Ordinary dichotomy and perturbations of the coefficient matrix of the linear impulsive differential equation

NEDELCHO VELEV MILEV and DRUMI DIMITROV BAINOV

1. Introduction

In relation to numerous applications in science and technology, in the last five years the theory of impulsive differential equations has developed intensively [3], [4], [5], [6], [10]. In the present paper one of the important properties of the ordinary dichotomy for linear impulsive differential equations is studied, namely that it is not destroyed under small perturbations of the coefficient matrix. We shall note that analogous questions about ordinary differential equations were considered in [7], [2], [1], [9].

2. Preliminary notes

Let \( t_0 < t_1 < \cdots < t_i < \cdots \), \( \lim t_i = \infty \) as \( i \to \infty \), be a given sequence of real numbers. Consider the linear differential equation with impulses at

fixed moments

\[ \frac{dx}{dt} = A(t)x, \quad t \neq t_i; \]

\[ x(t_i + 0) = B_i x(t_i), \quad i = 1, 2, \ldots \tag{1} \]

where the \((n \times n)\)-coefficient matrix \(A(t)\) is piecewise continuous in the interval \([t_0, +\infty)\) with points of discontinuity of the first kind at \(t = t_i\) and the impulse matrices \(B_i, i = 1, 2, \ldots\) are constant. The underlying vector space \(E\) is \(\mathbb{R}^n\) or \(\mathbb{C}^n\).

Remark 1. — For \(t \in [t_i + 0, t_{i+1}]\) the fundamental matrix \(X(t)\) of equation (1) admits the representation

\[ X(t) = U(t)U^{-1}(t_i + 0)B_iU(t_i)U^{-1}(t_i - 1 + 0)B_{i-1} \cdots B_1U(t_1)U^{-1}(t_0) \]

where \(U(t)\) is the fundamental matrix of the equation \(dx/dt = A(t)x\).

The matrix \(X(t)\) is continuously differentiable for \(t \neq t_i\) with points of discontinuity of the first kind at \(t = t_i\), i.e. \(X(t_i + 0) = B_iX(t_i)\). The fundamental matrix \(X(t)\) is invertible if and only if the impulse matrices \(B_i, i = 1, 2, \ldots\), are nonsingular.

Together with equation (1) we shall consider the perturbed equation

\[ \frac{dx}{dt} = (A(t) + \tilde{A}(t))x, \quad t \neq t_i; \]

\[ x(t_i + 0) = B_i x(t_i), \quad i = 1, 2, \ldots \tag{2} \]

where the matrix \(\tilde{A}(t)\) is piecewise continuous on the interval \([t_0, +\infty)\) with points of discontinuity of the first kind for \(t = t_i, i = 1, 2, \ldots\).

Let \(\tau_0\) be a fixed real number, \(\tau_0 \geq t_0\).

Definition 1 ([8]). — The subspace \(Y\) of the underlying vector space \(E\) induces an ordinary dichotomy of the solutions of equation (1) on the interval \([\tau_0, +\infty)\) if for some subspace \(Z\) supplementary to \(Y\) there exists a constant \(N\) such that all solutions \(x, y, z\) of equation (1) for which \(x = y + z\), \(y(\tau_0) \in Y\) and \(z(\tau_0) \in Z\) satisfy the conditions

\[ |y(t)| \leq N|x(s)| \text{ for } t \geq s \geq \tau_0 \text{ and } |z(t)| \leq N|x(s)| \text{ for } t \geq s \geq \tau_0. \tag{3} \]

When the fundamental matrix \(X(t)\) is invertible, Definition 1 can be written down in the following form.
**Ordinary dichotomy and perturbations of the coefficient matrix**

**Definition 2 ([8]).** The subspace $Y$ of the underlying vector space $E$ induces an ordinary dichotomy of the solutions of equation (1) on the interval $[\tau_0, +\infty)$ if for some projector $P(P^2 = P)$ with range $R(P) = Y$ there exists a constant $N$ such that

$$
\begin{align*}
&\left| X(t)X^{-1}(\tau_0)PX(\tau_0)X^{-1}(s) \right| \leq N \quad \text{for } t \geq s \geq \tau_0 \\
&\left| X(t)X^{-1}(\tau_0)(I - P)X(\tau_0)X^{-1}(s) \right| \leq N \quad \text{for } s \geq t \geq \tau_0
\end{align*}
$$

(4)

where $I$ stands for the unit matrix.

**Definition 3.** Let $P$ be a projector ($P^2 = P$). The function

$$
G(t, s) = \begin{cases} X(t)PX^{-1}(s) & \text{for } t \geq s \geq \tau_0; \\ X(t)(P - I)X^{-1}(s) & \text{for } s \geq t \geq \tau_0, \end{cases}
$$

will be called Green's function for equation (1).

We shall use the following properties of Green's function which are verified immediately:

$$
\frac{\partial G(t, s)}{\partial t} = A(t)G(t, s) \quad \text{for } t \neq s,
$$

$$
G(t_i + 0, t) = B_i G(t_i, t)
$$

and $$
G(t, t + 0) - G(t, t - 0) = -I \quad \text{for } t \neq t_i, i = 1, 2, \ldots
$$

**3. Main results**

**Theorem 1.** Let the impulse matrices $B_i, i = 1, 2, \ldots,$ of equation (1) be nonsingular and let the subspace $Y$ induce an ordinary dichotomy of the solutions of equation (1) on the interval $[t_0, +\infty)$ with a projector $P$ and a constant $N$. If

$$
\int_{t_0}^{\infty} \left| \tilde{A}(\theta) \right| \, d\theta = K < \frac{1}{N(2N + 1)}
$$

(5)

then the perturbed equation (2) also has an ordinary dichotomy on interval $[t_0, +\infty)$. 

- 129 -
Proof. — Let $X(t)$ be the fundamental matrix of equation (1) for which $X(t_0) = I$. The bounded solutions $y(t)$ of equation (2) are just the bounded solutions of the integral equation

$$y(t) = X(t)\eta + \int_{t_0}^{\infty} G(t, \theta)\tilde{A}(\theta)y(\theta)\,d\theta, \quad \eta \in Y,$$

since for $t \neq t_i$

$$\frac{dy(t)}{dt} = X'(t)\eta + \frac{d}{dt} \left( \int_{t_0}^{t} G(t, \theta)\tilde{A}(\theta)y(\theta)\,d\theta + \int_{t}^{\infty} G(t, \theta)\tilde{A}(\theta)y(\theta)\,d\theta \right) =$$

$$= A(t)X(t)\eta + \int_{t_0}^{\infty} A(t)G(t, \theta)\tilde{A}(\theta)y(\theta)\,d\theta +$$

$$+ G(t, t - 0)\tilde{A}(t)y(t) - G(t, t + 0)\tilde{A}(t)y(t) =$$

$$= (A(t) + \tilde{A}(t))y(t),$$

and for $t = t_i$

$$y(t_i + 0) = X(t_i + 0)\eta + \int_{t_0}^{\infty} G(t_i + 0, \theta)\tilde{A}(\theta)y(\theta)\,d\theta =$$

$$= B_i X(t_i)\eta + \int_{t_0}^{\infty} B_i G(t_i, \theta)\tilde{A}(\theta)y(\theta)\,d\theta = B_i y(t_i).$$

Denote by $H$ the Banach space of all bounded piecewise continuous vector-valued functions $y(t)$ in the interval $[t_0, +\infty)$ with points of discontinuity of the first kind at $t = t_i$, $i = 1, 2, \ldots$ and with a norm

$$||y|| = \sup_{t \geq t_0} |y(t)|.$$

The linear operator $Ty(t) = \int_{t_0}^{\infty} G(t, \theta)\tilde{A}(\theta)y(\theta)\,d\theta$ maps $H$ into itself since

$$|Ty(t)| \leq \int_{t_0}^{\infty} |G(t, \theta)||\tilde{A}(\theta)||y(\theta)|\,d\theta \leq NK||y||.$$

This implies that $|T| \leq NK < 1$ and by the contraction mapping principle the integral equation (6) for each $\eta \in Y$ has exactly one solution $y \in H$ which depends linearly on $\eta$, i.e. $y(t) = F(t)\eta$ where $F(t)$ is a bounded piecewise continuous matrix on the interval $[t_0, +\infty)$ with points of discontinuity of the first kind at $t = t_i$, $i = 1, 2, \ldots$ Moreover, from $y = X(t)\eta + Ty$ we obtain

$$||y|| \leq N|\eta| + |T||y| \leq N|\eta| + NK||y||,$$

- 130 -
Ordinary dichotomy and perturbations of the coefficient matrix

i.e.

\[ ||y|| \leq \frac{N}{1 - NK} |\eta| \quad \text{and} \quad |F(t)| \leq \frac{N}{1 - NK}. \]

Let \( \widetilde{Y} \) be the subspace of \( E \) consisting of the initial values \( y(t_0) \) of the bounded solutions of the integral equation (6)

\[
y(t_0) = \eta + \int_{t_0}^{\infty} \mathcal{G}(t_0, \theta) \tilde{A}(\theta) F(\theta) \eta \, d\theta =
\]

\[
= \eta - (I - P) \left( \int_{t_0}^{\infty} X^{-1}(\theta) \tilde{A}(\theta) F(\theta) \, d\theta \right) \eta =
\]

\[
= (I - (I - P)QP) \eta,
\]

where

\[
Q = (I - P) \left( \int_{t_0}^{\infty} X^{-1}(\theta) \tilde{A}(\theta) F(\theta) \, d\theta \right) P.
\]

The operator \( Q \) is bounded

\[ |Q| \leq N \cdot K \cdot \frac{N}{1 - NK} \cdot |P|. \]

The operator \( I - (I - P)QP \) maps the subspace \( Y \) onto \( \widetilde{Y} \). It has a bounded inverse one \( I + (I - P)QP \). The operator

\[
\widetilde{P} = (I - (I - P)QP) P (I - (I - P)QP)^{-1} = P - (I - P)QP
\]

is a projector with range \( R(\widetilde{P}) = \widetilde{Y} \). The supplementary projector \( I - \widetilde{P} = (I - P)(I + QP) \) has a range \( R(I - \widetilde{P}) = Z \).

First we shall estimate the solutions issuing from \( \widetilde{Y} \). By (6)

\[
\eta = X^{-1}(s)y(s) - X^{-1}(s) \int_{t_0}^{\infty} \mathcal{G}(s, \theta) \tilde{A}(\theta) y(\theta) \, d\theta =
\]

\[
= X^{-1}(s)y(s) - \int_{t_0}^{s} PX^{-1}(\theta) \tilde{A}(\theta) y(\theta) \, d\theta
\]

\[
- \int_{s}^{\infty} (P - I) X^{-1}(\theta) \tilde{A}(\theta) y(\theta) \, d\theta =
\]

\[
= PX^{-1}(s)y(s) - \int_{t_0}^{s} PX^{-1}(\theta) \tilde{A}(\theta) y(\theta) \, d\theta,
\]

\[ - 131 - \]
Hence for \( t > s \)

\[
y(t) = X(t)\eta + \int_{t_0}^{\infty} G(t, \theta) \tilde{A}(\theta)y(\theta) \, d\theta = \\
= X(t)PX^{-1}(s)y(s) - X(t) \int_{t_0}^{s} PX^{-1}(\theta) \tilde{A}(\theta)y(\theta) \, d\theta + \\
+ \int_{t_0}^{\infty} G(t, \theta) \tilde{A}(\theta)y(\theta) \, d\theta = \\
= X(t)PX^{-1}(s)y(s) + \int_{s}^{\infty} G(t, \theta) \tilde{A}(\theta)y(\theta) \, d\theta.
\]

Hence for \( t \geq s \)

\[
|y(t)| \leq N|y(s)| + N \int_{s}^{\infty} |\tilde{A}(\theta)||y(\theta)| \, d\theta.
\]

Let us fix \( s \) and set \( N|y(s)| = \alpha \). The cone of the nonnegative piecewise continuous functions \( \varphi(t) = |y(t)| \) is invariant with respect to the linear operator \( L\varphi(t) = N \int_{s}^{\infty} |\tilde{A}(\theta)||\varphi(\theta)| \, d\theta \). Hence

\[
L|y(\theta)| \leq L\alpha + L^2|y(t)| = NK\alpha + NKL|y(t)|,
\]

i.e.

\[
|y(t)| \leq \alpha + L|y(t)| \leq \alpha + \frac{NK\alpha}{1-NK} = \frac{\alpha}{1-NK}.
\]

Hence for \( t \geq s \)

\[
|y(t)| \leq \frac{N|y(s)|}{1-NK}. \tag{7}
\]

Let \( z(t) \) be a solution with initial condition \( z(t_0) \in Z \). From the formula

\[
z(s) = X(s)z(t_0) + \int_{t_0}^{s} X(s)X^{-1}(\theta)\tilde{A}(\theta)z(\theta) \, d\theta
\]

we express \( z(t_0) \) and in view of \((I - P)z(t_0) = z(t_0)\) for \( t < s \) we obtain that

\[
z(t) = X(t)(I - P)X^{-1}(s)z(s) - \int_{t_0}^{s} X(t)(I - P)X^{-1}(\theta)\tilde{A}(\theta)z(\theta) \, d\theta + \\
+ \int_{t_0}^{t} X(t)X^{-1}(\theta)\tilde{A}(\theta)z(\theta) \, d\theta = \\
= X(t)(I - P)X^{-1}(s)z(s) + \int_{t_0}^{t} X(t)PX^{-1}(\theta)\tilde{A}(\theta)z(\theta) \, d\theta - \\
- \int_{t}^{s} X(t)(I - P)X^{-1}(\theta)\tilde{A}(\theta)z(\theta) \, d\theta
\]
and get to the integral inequality

\[ |z(t)| \leq N|z(s)| + N \int_{t_0}^{s} |\tilde{A}(\theta)||z(\theta)|\,d\theta. \]

The linear operator \( L_1 \varphi(t) = N \int_{t_0}^{s} |\tilde{A}(\theta)||\varphi(\theta)|\,d\theta \) is monotone and, as for (7), we obtain that for \( t \leq s \)

\[ |z(t)| \leq \frac{N}{1 - NK} |z(s)|. \] (8)

Now let \( x(t) = y(t) + z(t) \) be an arbitrary solution of the differential equation (2). From the formula

\[ x(s) = X(s)x(t_0) + \int_{t_0}^{s} X(s)X^{-1}(\theta)\tilde{A}(\theta)x(\theta)\,d\theta \]

we express \( x(t_0) \) and in view of (6) we obtain that

\[ y(s) = X(s)Px(t_0) + \int_{t_0}^{\infty} G(s,\theta)\tilde{A}(\theta)y(\theta)\,d\theta = \]

\[ = X(s)PX^{-1}(s)x(s) - \int_{t_0}^{s} X(s)PX^{-1}(\theta)\tilde{A}(\theta)x(\theta)\,d\theta + \]

\[ + \int_{t_0}^{s} X(s)PX^{-1}(\theta)\tilde{A}(\theta)y(\theta)\,d\theta + \]

\[ + \int_{s}^{\infty} X(s)(P - I)X^{-1}(\theta)\tilde{A}(\theta)y(\theta)\,d\theta = \]

\[ = X(s)PX^{-1}(s)x(s) - \int_{t_0}^{s} X(s)PX^{-1}(\theta)\tilde{A}(\theta)z(\theta)\,d\theta + \]

\[ + \int_{s}^{\infty} X(s)(P - I)X^{-1}(\theta)\tilde{A}(\theta)y(\theta)\,d\theta. \]

In view of (7) and (8) we get to the inequality

\[ |y(s)| \leq N|x(s)| + N \int_{t_0}^{s} |\tilde{A}(\theta)||z(\theta)|\,d\theta + N \int_{s}^{\infty} |\tilde{A}(\theta)||y(\theta)|\,d\theta \leq \]

\[ \leq N|x(s)| + \frac{N^2 K}{1 - NK} |z(s)| + \frac{N^2 K}{1 - NK} |y(s)| \leq \]

\[ \leq \frac{N}{1 - NK} |x(s)| + \frac{2N^2 K}{1 - NK} |y(s)|, \]
Moreover,

\[ |y(s)| \leq \frac{N}{1 - NK - 2N^2K} |x(s)|. \]

From (7), (8), (9) and (10) we obtain that for \( t > s > t_0 \), \( |y(t)| \leq N_1|x(s)| \) and for \( t > s > t_0 \), \( |z(t)| \leq N_1|x(s)| \) where

\[ N_1 = \frac{N(1 + N - NK - 2N^2K)}{(1 - NK)(1 - NK - 2N^2K)} > 0, \]

i.e. the perturbed equation (2) has an ordinary dichotomy as well.

**Lemma 1** ([8]). — Let \( \tau_0 \) and \( \tau \) be fixed real numbers in the interval \([\tau_0, +\infty)\) and let the impulse matrices \( B_i, i = 1, 2, \ldots \), of equation (1) be nonsingular. If equation (1) has an ordinary dichotomy on the interval \([\tau_0, +\infty)\), then it has an ordinary dichotomy on the interval \([\tau, +\infty)\) as well.

**Corollary 1.** — Let the impulse matrices \( B_i, i = 1, 2, \ldots \), be nonsingular and let equation (1) have an ordinary dichotomy on the interval \([\tau_0, +\infty)\). If

\[ \int_{t_0}^{\infty} |\tilde{A}(\theta)| \, d\theta < \infty \]

then the perturbed equation (2) also has an ordinary dichotomy on the interval \([t_0, +\infty)\).

**Proof.** — Since the integral \( \int_{t_0}^{\infty} |\tilde{A}(\theta)| \, d\theta \) is convergent, then a sufficiently large number \( \tau_0 \) can be found such that condition (5) should hold. Since the impulse matrices \( B_i, i = 1, 2, \ldots \), are nonsingular, then equation (1) has an ordinary dichotomy with the same constant \( N \) on the interval \([\tau_0, +\infty)\) as well. Then by theorem 1 the perturbed equation (2) also has an ordinary dichotomy on the interval \([\tau_0, +\infty)\) and by lemma 1 it has an ordinary dichotomy on each interval \([\tau, +\infty)\), \( \tau \geq t_0 \) as well.
Ordinary dichotomy and perturbations of the coefficient matrix
