JOHN TATE

Residues of differentials on curves

Annales scientifiques de l’É.N.S. 4e série, tome 1, n° 1 (1968), p. 149-159

<http://www.numdam.org/item?id=ASENS_1968_4_1_1_149_0>
RESIDUES OF DIFFERENTIALS ON CURVES (')

BY JOHN TATE,
Harvard University.

This lecture contains a definition of the residues of differentials on curves, in terms of traces of certain linear operators on infinite dimensional vector spaces. All the standard theorems on residues follow easily from this definition, by proofs which are natural and independent of the characteristic of the ground field. In particular, the fact that "the sum of the residues is zero on a complete curve X" results directly, without computation, from the finiteness of the cohomology groups $H^i(X, \mathcal{O}_X)$, for $i = 0$ and 1, almost as though one had an abstract Stokes's Theorem available. I arrived at this treatment of residues by considering the special features of the one-dimensional case, after discussing with Mumford an approach of Cartier to Grothendieck's higher dimensional residue symbol (see Hartshorne, Residues and Duality, Springer lecture notes in Mathematics, vol. 20, 1966, p. 195).

For a good general account of the subject of residues and duality on curves, with references to other approaches, see Serre, Groupes algèbriques et corps de classes, Hermann, Paris, 1959, p. 24-35 and also p. 76-81.

1. TRACES. — Let $k$ be a fixed ground field and $V$ a vector space over $k$. We say that an endomorphism $\theta$ of $V$ is finite potent if $\theta^n V$ is finite dimensional for some $n$. For such $\theta$, a trace $\text{Tr}_V(\theta) \in k$ may be defined, having the properties:

(T) If $V$ is finite dimensional, then $\text{Tr}_V(\theta)$ is the ordinary trace;

\(')\) This paper is a slight revision and expansion of a lecture given at the Advanced Science Seminar in Algebraic Geometry, sponsored by the National Science Foundation, held at Bowdoin College, Brunswick, Maine, in the Summer of 1967. I wish to thank James Milne who wrote up the Notes of that lecture, which served as a first draft of this paper.
(T₁) If \( W \) is a subspace of \( V \), and \( \theta W \subseteq W \), then
\[
\text{Tr}_V(\theta) = \text{Tr}_W(\theta) + \text{Tr}_{V/W}(\theta);
\]

(\( T₃ \)) If \( \theta \) is nilpotent, then \( \text{Tr}_V(\theta) = 0 \).

Note that \( T₁, T₂, T₃ \) characterize traces; if \( W \) is a finite dimensional subspace of \( V \) such that \( \theta W \subseteq W \) and \( \theta^n V \subseteq W \), for some \( n \), then \( \text{Tr}_V(\theta) = \text{Tr}_W(\theta) \). Such \( W \) exist, for we may take \( W = \theta^n V \) for some large \( n \). (In fact, there is a unique minimal such \( W \), which equals \( \theta^n V \) for all sufficiently large \( n \).)

(\( T₄ \)) If \( F \) is a finite potent subspace of \( \text{End}(V) \) (i.e., if there exists an \( n \) such that for any family of \( n \) elements \( \theta_1, \ldots, \theta_n \in F \), the space \( \theta_1 \ldots \theta_n V \) is finite dimensional) then \( \text{Tr}_V : F \to k \) is \( k \)-linear.

Proof. — We may take \( F \) to be finite dimensional and compute the traces of all elements of \( F \) on the finite dimensional subspace \( W = F^n V \).

Property \( (T₄) \) seems the natural linearity property for \( \text{Tr}_V \), and is sufficient for our applications. I doubt whether the rule
\[
\text{Tr}_V(\theta_1 + \theta_2) = \text{Tr}_V(\theta_1) + \text{Tr}_V(\theta_2)
\]
holds in general, i.e., whenever all three endomorphisms \( \theta_1, \theta_2 \) and \( \theta_1 + \theta_2 \) are finitepotent, although I do not know a counter example. (If a counter example exists at all, then there will be one with \( \theta_1 \) and \( \theta_2 \) nilpotent, because every finitepotent endomorphism is the sum of a nilpotent one and one with finite range.)

(\( T₅ \)) If \( \varphi : V \to V \) and \( \psi : V \to V \) are \( k \)-linear and \( \varphi \psi \) is finite potent, then \( \psi \varphi \) is finite potent, and
\[
\text{Tr}_V(\varphi \psi) = \text{Tr}_V(\psi \varphi).
\]

Indeed, for large \( n \) the maps \( \varphi \) and \( \psi \) induce mutually inverse isomorphisms between the subspaces \( W' = (\psi \varphi)^n V' \) and \( W = (\varphi \psi)^n V \), under which the endomorphisms \( \psi \varphi | W' \) and \( \varphi \psi | W \) correspond.

Fix \( V \). A subspace \( A \) of \( V \) is "not much bigger" than a subspace \( B \) (notation \( A < B \)) if \( (A + B)/B \) is finite dimensional, or equivalently, if \( A \subseteq (B + W) \) for some finite dimensional \( W \); and \( A \) is "about the same size" as \( B \) (notation \( A \sim B \)) if \( A < B \) and \( B < A \). The following rules are easy to check:

- \( A < B \) and \( B < C \implies A < C \);
- \( A < B \implies \varphi(A) < \varphi(B) \), for any \( k \)-linear map \( \varphi \), and
\[
\sum_{i=1}^{n} A_i \subseteq \bigcap_{j=1}^{n} B_j \iff A_i \subseteq B_j \quad \text{all } i \text{ and } j.
\]
Fix a subspace $A$ of $V$; then define subspaces $E, E_0, E_1, E_2$ of $\text{End}(V)$ by

$$
0 \in E \iff \forall A < A, \quad 0 \in E_1 \iff \forall V < A, \quad 0 \in E_2 \iff \forall A < (o),$$
$$
0 \in E_0 \iff \forall 0 < A \quad \text{and} \quad \forall 0 < (o).
$$

**Proposition 1.** — $E$ is a $k$-subalgebra of $\text{End}(V)$; the $E_i$ are two-sided ideals in $E$; the $E$'s depend only on the $\sim$-equivalence class of $A$; we have $E_1 \cap E_2 = E_0$ and $E_1 + E_2 = E$; and $E_0$ is finite potent.

**Proof.** — Let $\pi : V \to A$ be a linear projection. Then $\pi - \pi \in E_2, \pi \in E_1$ and $\pi + (\pi - \pi) = 1$, so $E_1 + E_2 = E$. The other statements are obvious.

Thus there is a $k$-linear map $\text{Tr}_V : E_0 \to k$.

**Proposition 2.** — Suppose either $\varphi \in E_0$ and $\psi \in E_i$ or $\varphi \in E_i$ and $\psi \in E_2$. Then the commutator $[\varphi, \psi] = \varphi \psi - \psi \varphi$ is in $E_0$ and has zero trace.

**Proof.** — Trivial from the definition of the $E_i$ and (T$_*$).

2. **Abstract Residues.** — Let $K$ be a commutative $k$-algebra (with $1$), $V$ a $K$-module, and $A$ a $k$-subspace of $V$ such that $fA < A$ for all $f \in K$. With notations $E$ and $E_i$ (relative to $V$ and $A$) as above, this last condition means that $K$ operates on $V$ through $E \subseteq \text{End}_k(V)$, and we shall in what follows habitually use the same letter $f$ to denote an element of $K$ and its image in $E$.

**Theorem 1 (Definition of residue).** — In the situation just described there exists a unique $k$-linear "residue map"

$$
\text{res}_v : \Omega^1_{k/k} \to k
$$

such that for each pair of elements $f$ and $g$ in $K$ we have

$$
\text{res}_v(fdg) = \text{Tr}_V([f_1, g_1])
$$

for every pair of endomorphisms $f_1$ and $g_1$ in $E$ satisfying the following conditions:

(a) Both $f \equiv f_1 (\text{mod } E_2)$ and $g \equiv g (\text{mod } E_2)$;

(b) Either $f \in E_1$ or $g \in E_1$.

Given $f$ and $g$ in $K$ it is always possible to find $f_1$ and $g_1$ satisfying (a) and (b) because $E = E_1 + E_2$. Then $[f_1, g_1] \in E_1$ by (b) and $[f_1, g_1] = [f, g] = 0 (\text{mod } E_2)$ by (a). Hence $[f_1, g_1] \in E_1 \cap E_2 = E_0$ and $\text{Tr}_V([f_1, g_1])$ is defined. By proposition 2 this quantity is unaltered if $f_1$ or $g_1$ is changed by an element of $E_2$ provided that the other is in $E_1$, and by (T$_*$) it is a $k$-bilinear function of $f$ and $g$. Thus there is a linear map $r : K \otimes_k K \to k$, such that $r(f \otimes g) = \text{Tr}_V([f_1, g_1])$. Recall that by the very definition of $\Omega^1$ there is a $k$-linear map

$$
c : K \otimes_k K \to \Omega^1_{k/k}
$$
such that \( c(f \otimes g) = f^g \) and such that:

(i) \( c \) is surjective;
(ii) \( \ker(c) \) is generated over \( k \) by elements of the form

\[ f \otimes gh - fg \otimes h - fh \otimes g. \]

By (i), \( \text{res}^i \) (if it exists) can only be the unique map \( r' \) such that \( r'c = r \) in the diagram

\[
\begin{array}{ccc}
K \otimes_k K & \xrightarrow{c} & k \\
\downarrow & & \downarrow \\
\Omega_{k/k} & \xrightarrow{r} & \text{res}^i
\end{array}
\]

Such a map \( r' \) exists if and only if \( r \) vanishes on the kernel of \( c \). To see that it does, let \( f, g, \) and \( h \in K \), choose suitable \( f', g', \) and \( h' \) in \( E_i \), and then use \( (f^g)_i = f'_i g'_i \), etc., and the identity

\[
[f, g, h] - [f, g', h'] - [f, h', g] = 0.
\]

Thus \( \text{res}^i \) exists and is unique.

**Remark.** — For given \( f \) and \( g \) in \( K \), the computation of \( \text{Res}(f \otimes dg) \) can be effected in finite terms as follows. Let

\[
B = A + fA, \\
C = B \cap f^{-1}(A) \cap (f^g)^{-1}(A) = \{ v \in B \mid f^v \in A \text{ and } f^v v \in A \}.
\]

Let \( \pi \) be a \( k \)-linear projection of \( (A + fA + fgA) \) onto \( A \). Then \( \dim(B/C) \) is finite and

\[
\text{res}^i(f \otimes dg) = \text{Tr}_{B/C}(\{ \pi f, g \}).
\]

Indeed, if we extend \( \pi \) to a projection of all of \( V \) onto \( A \), then \( \pi f \in E_i \) and \( \pi f = f \mod E_i \), so \( \text{res}_i(f dg) = \text{Tr}_v(\{ \pi f, g \}) \). On the other hand \( \{ \pi f, g \} = \pi fg - g \pi f \) maps \( V \) into \( B \), and \( C \) into \( 0 \) (because \( f g = g f \)). Hence \( (\star) \) holds by property \( (T_3) \) of \( \text{Tr}_v \).

**Properties of \( \text{res}^i \):**

(R1) *If \( V \supseteq V' \supseteq A \) and \( KV' = V' \), then \( \text{res}^i = \text{res}^{i'} \). Moreover \( \text{res}_i = \text{res}_i^0 \) if \( A \sim A' \).*

These statements are obvious from the above remark and from the definition of \( \text{res} \). In view of the first statement we can usually omit the superscript \( V \) on \( \text{res}_i \) from now on.

(R2) *(Continuity in \( f \) and \( g \)) If \( fA + f^gA \subseteq A \) then \( \text{res}_i(f \otimes dg) = 0 \). In particular, this is so if \( fA \subseteq A \) and \( gA \subseteq A \). The function \( \text{Res}_i \) is identically 0 if \( A \) is a \( K \)-submodule of \( V \).*
Proof. — The first condition on $f$ and $g$ implies $B = C$ in the above remark, and the later statements follow from the first.

(R$_3$) Let $g \in K$. Then $\text{res}_A(g^n dg) = 0$ for all integers $n \geq 0$, and moreover the same holds for all $n \leq -2$ if $g$ is invertible in $K$. In particular, $\text{res}_A(dg) = 0$ for all $g \in K$.

Proof. — Choose $g_1 \in E_1$, such that $g_1 \equiv g \pmod{E_2}$. Then if $n \geq 0$ we have $\text{res}_A(g^n dg) = \text{Tr}_V([g^n, g_1]) = 0$ because $g_1^n$ and $g_1$ commute. If $g$ is invertible then $g^{2-n}dg = -(g^{-1})^n d(g^{-1})$, which has zero residue by the preceding statement, if $n \geq 0$.

(R$_4$) If $g$ is invertible in $K$, and $h \in K$ is such that $hA \subseteq A$, then

$$\text{res}_A(hg^{-1} dg) = \text{Tr}_{A/[A \cap gA]}(h) - \text{Tr}_{gA/[A \cap gA]}(h).$$

In particular, if $g$ is invertible and $gA \subseteq A$, then

$$\text{res}_A(g^{-1} dg) = \dim_k (A/gA).$$

Proof. — Take $f = hg^{-1}$ and apply the above remark. We have $[\pi f, g] = \pi h - \pi g^{-1}$, where $\pi = g \pi g^{-1}$ is a projection of $V$ onto $gA$. Since both $A$ and $gA$ are stable under $h$ we have

$$\text{res}_A(f dg) = \text{Tr}_{A+gA/[A \cap gA]}(\pi h) - \text{Tr}_{gA/[A \cap gA]}(g \pi g^{-1} h)$$

and the result follows.

(R$_5$) Suppose that $B$ is another $k$-subspace of $V$ such that $fB < B$ for all $f \in K$, then

$$f(A + B) \subseteq A + B \quad \text{and} \quad f(A \cap B) \subseteq A \cap B, \quad \text{for all } f \in K,$$

and we have

$$\text{res}_A + \text{res}_B = \text{res}_{A + B} + \text{res}_{A \cap B}.$$

Proof. — It is easy to see that we can choose projections $\pi_A$, $\pi_B$, $\pi_{A+B}$, $\pi_{A \cap B}$ of $V$ onto $A$, $B$, $A + B$, $A \cap B$ respectively, such that

$$\pi_A + \pi_B = \pi_{A+B} + \pi_{A \cap B}.$$ 

Notice that if we knew that $\text{Tr}_V$ was linear, we would be finished. Nevertheless, both $[\pi_A f, g]$ and $[\pi_{A+B} f, g]$ carry $V$ into $A + B$, and $A + B$ into $A$, and $A$ into $(0)$ (mod finite dimensional subspaces), so they belong to a finite potent subspace of $V$. Hence,

$$\text{res}_A f dg - \text{res}_{A+B} f dg = \text{Tr}_V([\pi_A f, g]) - \text{Tr}_V([\pi_{A+B} f, g])$$

$$= \text{Tr}_V([\pi_A - \pi_{A+B}] f, g])$$

$$= \text{Tr}_V([\pi_{A \cap B} - \pi_B] f, g])$$

which, by a similar argument, may be shown to equal $\text{res}_{A \cap B} f dg - \text{res}_B f dg$. 

Let $K'$ be a commutative $K$ algebra which is a free $K$-module of finite rank. Let $V' = K' \otimes_K V$ and let $A' = \sum x_i \otimes A \subset V'$, where $(x_i)$ is a $K$-base for $K'$. Then $f' A' < A'$ for all $f' \in K'$, the $\sim$-equivalence class of $A'$ depends only on that of $A$, not on the choice of basis $(x_i)$, and we have

$$\text{Res}_A(f \ d g) = \text{Res}_A((\text{Tr}_{K'/K} f) \ d g) \quad \text{for } f' \in K' \text{ and } g \in K.$$

**Proof.** — A $k$-endomorphism $\varphi$ of $V'$ can be expressed as an $n \times n$ matrix $(\varphi_{ij})$ of endomorphisms of $V$ by the rule

$$\varphi \left( \sum_{i} x_i \otimes v_i \right) = \sum_{i} x_i \otimes \varphi_{ij} v_i$$

for $v_i \in V$. If $F$ is a finite potent subspace of $\text{End}_k V$, then the $\varphi$'s such that $\varphi_{ij} \in F$ for all $i, j$ form a finite potent subspace $F'$ of $\text{End}_k V'$, and we have $\text{Tr}_V \varphi = \sum \text{Tr}_V (\varphi_{ij})$ for all $\varphi \in F'$, as one sees by decomposing the matrix $(\varphi_{ij})$ into the sum of a diagonal matrix and two nilpotent triangular matrices, one of the latter having zeros on and below the diagonal, the other having zeros on and above the diagonal. Now write $f' x_j = \sum x_i f_{ij}$ with $f_{ij} \in K$. Let $\pi$ be a $k$-linear projection of $V$ on $A$ and put $\pi' \left( \sum x_i \otimes v_i \right) = \sum x_i \otimes \pi v_i$. Then $\pi'$ is a projection of $V'$ onto $A'$, and

$$[f' \pi', g]_{ij} = [f_{ij} \pi, g].$$

The desired result follows now because $\text{Tr}_{K'/K} f = \sum_{i} f_{ii}$.

3. **Algebraic Curves.** — Let $X$ be a connected, regular scheme of dimension 1, proper over a ground field $k$, and let $\bar{K} = k(X)$ be its function field. Then $X$ is determined up to a $k$-isomorphism by $K$ and $K$ may be any function field in one variable over $k$.

The closed points $p$ of $X$ correspond to the discrete valuation rings $O_p$ with field of fractions $K$ which contain $k$. Write $A_p = \hat{O}_p$, the completion of $O_p$, and write $K_p$ for the field of fractions of $A_p$ (so $K_p$ is the completion of $K$ with respect to the valuation defined by $O_p$).

**Definition.** — $\text{res}_p : \Omega^1_{k/k} \to k$ is the $k$-linear map such that

$$\text{res}_p f \ d g := \text{res}_p^{\ast}(f \ d g).$$

This definition makes sense, for if $t_p$ is a prime element in $A_p$, then the residue field $k(p) = A_p/t_p A_p$ has finite dimension (equal to the degree of $p$ relative to $k$) and so, by induction, $A_p = t_p^n A_p$ for all integers $n$. 
Now, for any non-zero $f$ in $K$ (or $K_p$) we have $fA_p = t^nA_p$ for some $n$, hence in particular, $fA_p < A_p$ for all $f \in K_p$.

**Theorem 2.** — Let $p$ be a $k$-rational point of $X$, so $k[[t]] \approx A_p$ and $k((t)) \approx K_p$. If $f = \sum a_it^i$ and $g = \sum b_it^i$ are two elements of $K$ (or $K_p$), then

$$\text{res}_p f dg = \text{coefficient of } t^{-1} \text{ in } f(t)g'(t) = \sum_{v + \mu = 0} \mu a_v b_\mu.$$

**Proof.** — By (R$_3$), we may assume that only finitely many of the $a_v$ and $b_\mu$ are non-zero. Then $f dg = f(t)g'(t) dt$, and by (R$_3$) only the term in $t^{-1}$ can give non-zero residue. By (R$_1$) we have

$$\text{res}_A (t^{-1} dt) = \dim_k k(p) = 1.$$

**Remark.** — One often defines $\text{res}_p f dg$ by the above expression, but in characteristic $\neq 0$, it is not immediately obvious that the coefficient in question is independent of the choice of the uniformizing parameter $t$.

**Theorem 3.** — Let $S$ be any set of closed points $p$. Put $O(S) = \bigcap_{p \in S} O_p \subset K$

Then for $\omega \in \Omega^1_{k/k}$ we have

$$\sum_{p \in S} \text{res}_p(\omega) = \text{res}^K_{O(S)}(\omega),$$

almost all terms of the sum being zero.

**Corollary.** — We have $\sum \text{res}_p(\omega) = 0$ if the sum is taken over all closed points $p$ of the complete curve $X$.

The corollary follows from the theorem because, $X$ being proper over $k$, the space $O(X) = H^0(X, \mathcal{O}_X)$ is finite dimensional. Hence $\text{res}_{O(X)} = 0$, by (R$_1$), because $O(X) \sim (\omega)$.

To prove the theorem, let

$$A_S = \prod_{p \in S} A_p,$$

$$V_S = \prod_{p \in S} K_p = \{ f = (f_p) \mid f_p \in K_p \text{ for all } p \text{ and } f_p \in A_p \text{ for almost all } p \}.$$ 

We may assume $S$ non-empty. Then $K$ may be regarded as a subspace of $V_S$ by means of the diagonal embedding $f \mapsto (f_p)$, where $f_p = f$ for all
$p \in S$. Considering the lattice of subspaces of $V_S$ pictured at the right, and using (Rs) we conclude that

$$
\text{res}_{\Lambda_\psi} + \text{res}_K = \text{res}_0(S) + \text{res}_{(K + \Lambda_\psi)} .
$$

\begin{equation}
\begin{array}{ll}
V_S & \\
| & \\
K + \Lambda_\psi & \\
| & \\
| & \\
K_\cap \Lambda_\psi = O(S) \\
(0)
\end{array}
\end{equation}

But $\text{res}_K = 0$ because $K$ is a $K$-module, and $\text{res}_{K + \Lambda_\psi} = 0$ because $V_S/(K + \Lambda_\psi)$ is finite dimensional (see below). Thus we have only to prove $\text{res}_{\Lambda_\psi}(\omega) = \sum_{\rho \in S} \text{res}_\rho(\omega)$.

Let $\omega = f dg$, let $S'$ be a finite subset of $S$ which contains all poles of $f$ or $g$, and let $T = S - S'$. Then

$$
V_S = V_T \times \prod_{\rho \in S'} K_\rho \quad \text{and} \quad A_S = A_T \times \prod_{\rho \in S'} A_\rho .
$$

From (Rs) it follows that

$$
\text{res}_{\Lambda_\psi}(f dg) = \text{res}_{\Lambda_\psi}(f dg) + \sum_{\rho \in S'} \text{res}_\rho(f dg) .
$$

But by our choice of $S'$, we have $\text{res}_{\Lambda_\psi}(f dg) = 0$ and $\text{res}_\rho(f dg) = 0$ for $\rho \in T$.

To prove that $V_S/(K + \Lambda_\psi)$ is finite dimensional it suffices to treat the case $S = X$ because the projection $V_X \to V_S$ is surjective. For $S = X$ we have $V_X/(K + \Lambda_\psi) \simeq H^1(X, \mathcal{O}_X)$ which is finite dimensional because $X$ is proper over $k$. This last well-known isomorphism follows from the exact sequence

$$
o \to \mathcal{O}_X \to K^0 \xrightarrow{\delta} K' \to 0
$$

of abelian sheaves on $X$, in which for any open $U \subset X$ we let $K^0(U) =$ Image of $K$ in $V_U$, and $K'(U) = V_U/A_U = \bigoplus_{\rho \in U} K_\rho/A_\rho$, the map $\delta(U)$ being induced by $V_U \to V_U/A_U$. The restriction maps for $U' \subset U$ are surjective; hence the sheaves $K'$ have trivial cohomology in dimensions greater than zero.
The homomorphism \( \delta \) is surjective because \( K + A_p = K_p \) for each \( p \), and \( (\text{Ker} \delta) = O_X \) because

\[
(\text{Ker} \delta) (U) = \text{Ker} (\delta (U)) = O(U) \quad \text{for each } U.
\]

Thus the sequence is exact, and

\[
H^1(X, \mathcal{O}_X) = \text{Coker} (\delta (X)) = V_X/(K + A_X).
\]

**Theorem 4.** — Let \( X' \to X \) be a surjective morphism of curves of the type we are considering, corresponding to the inclusion of function fields \( K \subset K' \). Then for \( f \in K' \), \( g \in K \), and \( p \in X \)

\[
\sum_{p' \mid p} \text{res}_{p'}(f' \, dg) = \text{res}_p ((\text{Tr}_{K/K}, f') \, dg).
\]

Similarly, if \( p' \in X' \) has image \( p \) in \( X \), \( f' \in K'_p \), and \( g \in K_p \), then

\[
\text{res}_{p'}(f' \, dg) = \text{res}_p ((\text{Tr}_{K'/K_p}, f') \, dg).
\]

These formulas (each of which implies the other in virtue of the fact that "the global trace is the sum of the local traces") both follow immediately from (Re), because the integral closure of \( O_p \) (resp. \( K_p \)) in \( K' \) (resp. \( K'_p \)) is a finite \( O_p \) (resp. \( A_p \)) module.

**Remark.** — The standard proof that the sum of the residues is zero is to use Theorem 4 to reduce to the case \( X \) is the projective line, and then to verify that the sum is zero by direct computation in that special case.

4. **Duality.** — For completeness we finish with a rough sketch of the "duality theorem". The idea is that for an arbitrary regular curve \( X \) proper over \( k \) there is a "dualizing sheaf" \( J_{X/k} \), and if \( X \) is smooth over \( k \), then \( J_{X/k} \) can be identified with \( \Omega^1_{X/k} \) via the theorems on residues.

Let \( X, K, \) etc., be as in the preceding section, and let \( V = V_X \) and \( A = A_X \). For each divisor \( D \) on \( X \), let

\[
V(D) = \{ f = (f_p) \in V | \text{ord}_p f_p \geq \text{ord}_p D \text{ for all } p \in X \}.
\]

Thus for example \( V(0) = A \). By the same method as in the paragraph before theorem 4 above, one shows that for each \( D \)

\[
H^1(X, \mathcal{O}_X(D)) \approx V/(K + V(D)).
\]
The "dualizing sheaf" on $X_{/k}$ is the invertible sheaf $J_{X/k}$ whose stalk at the generic point is

$$J_{k/k} = \{ \lambda \in \text{Hom}_k(V, k) \mid \lambda(K + V(D)) = 0 \text{ for some divisor } D \} \cong \lim_{\rightarrow} (H^0(X, \mathcal{O}_X(D))^*$$

where $*$ denotes $k$-linear dual, and whose stalk at each special point $p$ is

$$J_p = \{ \lambda \in J_{k/k} \mid \lambda(A_p) = 0 \},$$

so that for each open $U \subset X$ we have $J_{X/k}(U) = \bigcap_{p \in U} J_p \subset J_{k/k}$. For the proof that this $J_{X/k}$ is an invertible sheaf on $X$, see Serre, loc. cit., or Chevalley, Introduction to the theory of algebraic functions of one variable, Math. Surveys, VI, New York, 1951. The sheaf $J_{X/k}$ is just constructed in such a way that the duality theorem

$$H^p(J_{X/k}(-D)) = \text{Hom}_k(V/(K + V(D)), k) \cong H^0(X, \mathcal{O}_X(D))^*$$

is a tautology and more generally it is easy to show that

$$H^p(J_{X/k} \otimes \mathcal{O}_X L^{-1}) \cong H^p(X, L)^*$$

for every locally free sheaf $L$ of finite rank over $\mathcal{O}_X$.

There is a canonical homomorphism

$$\Omega_{X/k}^1 \to J_{X/k}$$

which is characterized by the following action at the generic stalk

$$(c\omega)(f) = \langle f, \omega \rangle = \sum_{p \in X} \text{res}_p(f_p \omega)$$

for $\omega \in \Omega_{X/k}^1$ and $f = (f_p) \in V$. [Note that $(c\omega)(K) = 0$ by the corollary to theorem 3, and $(c\omega)(V(D)) = 0$ for some $D$ by $(R_2)$. Property $(R_2)$ also shows that the given $c$ at the generic stalk extends uniquely to a sheaf homomorphism, since $J_{X/k}$ is torsion free.]

Chevalley (loc. cit.) defined the differentials of $K/k$ to be elements $\lambda \in J_{k/k}$, but then had to go to some length to explain his "differential" $dx$, and to even greater length to prove $d(x+y) = dx + dy$! The key fact is

**Theorem 5.** — The homomorphism $c : \Omega_{X/k}^1 \to J_{X/k}$ is an isomorphism at all points $p$ where $X$ is smooth over $k$.

(In particular the map $\Omega_{X/k}^1 \to J_{k/k}$ at the generic stalk is an isomorphism, i.e., non-zero, if $K/k$ is separably generated.)
Corollary. — If $X/k$ is smooth (and in particular if $k$ is perfect), then for every invertible sheaf $L$ on $X$ we have

$$H^i(X, L) \cong H^0(\Omega^{1}_{X/k} \otimes L^{-1}).$$

Proof of Theorem 5. — Suppose $X/k$ is smooth at $p$. Then $\Omega^1_p$ and $J_p$ are free $O_p$-modules of rank 1, and $J_p$ is generated by any element $\lambda \in J_p$ such that $\lambda \not\in t_p J_p$, i.e., such that $\lambda(t_p^{-1} A_p) \neq 0$, where $t_p$ is a prime element of $O_p$. The element $\lambda = c(d t_p)$ has this property if the residue field $k(p)$ is separable over $k$, by (R4). The general case can be reduced to this one by a ground field extension $k \rightarrow k'$, or can be treated directly by a projection of $X$ onto the projective line which is étale at $p$.
