## COMMENTS ON A PAPER OF BROWN AND GUIVARC'H

BY CALVIN C. MOORE <sup>(1)</sup> AND JONATHAN ROSENBERG <sup>(2)</sup>

---

In a recent paper [2], Brown and Guivarc'h announce a proof of the following conjecture from [1]: Let  $G$  be a connected Lie group with radical  $R$  such that  $G/R$  has finite center; then  $G$  is type T in the sense of [1] if and only if the eigenvalues of  $\text{ad}(X)$  restricted to the Lie algebra  $\mathcal{L}(R)$  of  $R$  are purely imaginary for every  $X$  in the Lie algebra  $\mathcal{L}(G)$  of  $G$ . The proof given, however, has a gap in it, and in particular the crucial Proposition 4 is clearly false as stated. The difficulty occurs in the next to last sentence of the proof of this Proposition for it is surely possible for  $G \cap V$  to leave invariant a compact set in  $\mathcal{G}_p(V)$ , for instance a one point set consisting of an affine subspace containing  $G \cap V$ . We shall show how the difficulty can be repaired by modifying both Propositions 4 and 5; in the end, the modified version is a bit more direct than the original version. We also show that the condition in the theorem that  $G/R$  have finite center is necessary; in fact, we show that the universal covering group of  $SL_2(\mathbf{R})$  fails to have property T.

Specifically, Proposition 4 should be modified to read as follows:

**PROPOSITION 4'.** — *Let  $G$  be a connected Lie group contained in the affine group of a vector space  $V$ . If  $G \supset V$ , and if  $G$  is type T, then  $G$  is type R.*

*Proof.* — The given proof applies directly except that the affine Grassmann manifold  $\mathcal{G}_r(V)$  (use some letter other than  $p$ ) must be chosen so that  $0 < r < \dim V$  which is possible by the proof of Proposition 3. The next to last sentence of the proof must be changed; the point is that if a compact subset  $C$  of  $\mathcal{G}_r(V)$  is invariant under a subspace  $V'$  of  $V$ , then  $C$  must consist of affine subspaces parallel to  $V'$ . In particular, if  $V' = V$ , we have an impossibility since  $r < \dim V$ . This completes the proof.

Now Proposition 5 has to be strengthened as follows:

**PROPOSITION 5'.** — *Let  $G$  be a connected Lie group with radical  $R$  (which is non-compact) and nil-radical  $N$ . Then there exists a homomorphism  $h$  of  $G$  onto a group  $h(G)$  such that*

the kernel of  $h$  operates unipotently on  $\mathcal{L}(\mathbf{R})$  and such that either: (i)  $h(\mathbf{G}) \subset \text{GA}(\mathbf{V})$  for some vector space  $\mathbf{V}$  and  $h(\mathbf{N}) \supset \mathbf{V}$ , or else, (ii)  $h(\mathbf{G})$  is a solvable group.

*Proof.* — Exactly as in the paper, one reduces to the case when  $\mathbf{N}$  is a vector group. Let  $\mathcal{S}$  be a Levi factor for  $\mathcal{L}(\mathbf{G})$  so that  $\mathcal{L}(\mathbf{G}) = \mathcal{L}(\mathbf{R}) + \mathcal{S}$ . Now let  $\mathcal{L}(\mathbf{N}_0)$  be the subspace of  $\mathcal{L}(\mathbf{N})$  where  $\mathcal{S}$  acts trivially and let  $\mathbf{N}_0$  be the corresponding vector subgroup of  $\mathbf{N}$ . If  $\mathbf{N} = \mathbf{N}_0$ , then as  $\mathcal{S}$  acts trivially on  $\mathcal{L}(\mathbf{R})/\mathcal{L}(\mathbf{N})$  and as  $\mathcal{S}$  is semisimple,  $\mathcal{S}$  acts trivially on  $\mathcal{L}(\mathbf{R})$  so that  $\mathcal{L}(\mathbf{G})$  is the Lie algebra direct sum of  $\mathcal{L}(\mathbf{R})$  and  $\mathcal{S}$ . The commutator subalgebra of  $\mathcal{L}(\mathbf{G})$  is  $[\mathcal{L}(\mathbf{R}), \mathcal{L}(\mathbf{R})] + \mathcal{S} \subset \mathcal{L}(\mathbf{N}) + \mathcal{S}$  which acts nilpotently on the radical  $\mathcal{L}(\mathbf{R})$ . Hence, the commutator subgroup  $[\mathbf{G}, \mathbf{G}]$  of  $\mathbf{G}$  acts unipotently on  $\mathcal{L}(\mathbf{R})$  and hence so does its closure  $\mathbf{G}_1$ . In this case, we choose  $h$  to be the projection of  $\mathbf{G}$  onto  $\mathbf{G}/\mathbf{G}_1$  and (ii) holds.

Now if  $\mathbf{N}_0 \neq \mathbf{N}$ , we note that  $\mathbf{N}_0$  is a normal subgroup of  $\mathbf{G}$  since  $\mathbf{N}$  is abelian and since  $\mathcal{L}(\mathbf{R}/\mathbf{N})$  is central in  $\mathcal{L}(\mathbf{G}/\mathbf{N})$ . Since  $\mathcal{S}$  is semisimple and acts trivially on  $\mathcal{L}(\mathbf{R})/\mathcal{L}(\mathbf{N})$ , we may find a subspace  $\mathcal{A}$  of  $\mathcal{L}(\mathbf{R})$  complementary to  $\mathcal{L}(\mathbf{N})$  which is centralized by  $\mathcal{S}$ . Since  $[\mathcal{A}, \mathcal{A}]$  is also centralized by  $\mathcal{S}$ , it is contained in  $\mathcal{L}(\mathbf{N}_0)$ . Dividing out by  $\mathbf{N}_0$ , let  $\mathbf{G}' = \mathbf{G}/\mathbf{N}_0$ ,  $\mathbf{R}' = \mathbf{R}/\mathbf{N}_0$ ,  $\mathbf{N}' = \mathbf{N}/\mathbf{N}_0$ , and let  $\mathcal{A}' \simeq \mathcal{A}$ ,  $\mathcal{S}' \simeq \mathcal{S}$  be the images of  $\mathcal{A}$  and  $\mathcal{L}$  in  $\mathcal{L}(\mathbf{G}')$ . (Note that  $\mathbf{R}'$  is the radical of  $\mathbf{G}'$ , but that  $\mathbf{N}'$  may be smaller than the nil-radical of  $\mathbf{G}'$ .) Then  $\mathcal{A}'$  is an abelian subalgebra and  $\mathcal{S}' + \mathcal{A}'$  is a complement to  $\mathcal{L}(\mathbf{N}')$  so that  $\mathcal{L}(\mathbf{G}')$  is the semi-direct product of  $\mathcal{L}(\mathbf{N}')$  and  $\mathcal{S}' + \mathcal{A}'$ . Now let  $\mathbf{H}$  be the connected subgroup of  $\mathbf{G}$  with Lie algebra  $\mathcal{S}' + \mathcal{A}'$ , and let  $\overline{\mathbf{H}}$  be its closure. Then  $\overline{\mathbf{H}} \cap \mathbf{N}'$  consists of elements  $n$  such that  $\text{Ad}(n)$  is trivial on  $\mathcal{L}(\mathbf{N}')$  and on  $\mathcal{L}(\mathbf{G}')/\mathcal{L}(\mathbf{N}')$  and which stabilize  $\mathcal{S}' + \mathcal{A}'$ . That implies that  $\text{Ad}(n)$  is the identity, or in other words, that  $n$  is in the center of  $\mathbf{G}'$ . However, by the construction of  $\mathbf{N}_0$ , and semi-simplicity of  $\mathcal{S}'$ , this implies that  $n = e$ . Thus,  $\overline{\mathbf{H}} \cap \mathbf{N}' = \{e\}$  so  $\mathbf{H} = \overline{\mathbf{H}}$  is closed and  $\mathbf{G}'$  is the semi-direct product of  $\mathbf{N}'$  and  $\mathbf{H}$ .

We choose our vector space  $\mathbf{V}$  to be  $\mathbf{N}'$ ; for  $g \in \mathbf{G}$ , let  $g'$  be its image in  $\mathbf{G}'$  and write  $g' = \tau(g)\rho(g)$  with  $\tau(g) \in \mathbf{V}$ , and  $\rho(g) \in \mathbf{H}$ . Now we let  $h(g)v = g'vg'^{-1} + \tau(g)$  for  $v \in \mathbf{V}$ ; then  $h$  is a homomorphism of  $\mathbf{G}$  into  $\text{GA}(\mathbf{V})$ . Moreover  $h(\mathbf{N}) = \mathbf{V}$  and the kernel of  $h$  consists of elements  $g \in \mathbf{G}$  whose projection in  $\mathbf{G}'$  lies in  $\mathbf{H}$  and which act trivially on  $\mathbf{V}$ . Thus the kernel surely acts unipotently on  $\mathcal{L}(\mathbf{R})$  and (i) holds. Proposition 5' is proved.

The proof of the main theorem now proceeds as in [2] if  $h$  satisfies (i) and is trivial if  $h$  satisfies (ii).

We turn now to the second point about necessity of the condition that  $\mathbf{G}/\mathbf{R}$  have finite center. Let  $\mathbf{G}$  be semisimple with center  $\mathbf{Z}$ . By Proposition V.1 of [1]  $\mathbf{G}$  will fail to have property T if and only if there is an open semigroup  $\mathbf{S}$  in  $\mathbf{G}$  such that  $\mathbf{S}\mathbf{S}^{-1} \cap \mathbf{Z}$  has infinite index in  $\mathbf{Z}$ . Now let  $\mathbf{G}$  be universal covering group of  $\mathbf{G}_0 = \text{SL}_2(\mathbf{R})$ , so that  $\mathbf{Z} = \mathbf{Z}$ , the integers, and let  $\mathbf{S}_0$  be the open semigroup of  $\text{SL}_2(\mathbf{R})$  consisting of matrices with all entries strictly positive. It is known that  $\mathbf{S}_0\mathbf{S}_0^{-1}$  meets the center of  $\mathbf{G}_0$  in only one point. Now on page 46 of [3], there is constructed a very explicit cross section  $s: \mathbf{G}_0 \rightarrow \mathbf{G}$  for the group extension so that the corresponding cocycle  $b$  from  $\mathbf{G}_0 \times \mathbf{G}_0$  into  $\mathbf{Z}$  defined

by  $s(g)s(h) = b(g,h)s(gh)$  is explicitly computable. The cross section  $s$  is continuous and hence a homeomorphism on a dense open set  $D$ , specifically, the dense double coset of the triangular subgroup of  $G_0$ . It is clear that  $S_0 \subset D$ , and a direct calculation using the formulas on page 46 of [3] shows that the cocycle is trivial on  $S_0 \times S_0$  and that  $s(g^{-1}) = s(g)^{-1}$  for  $g \in S_0$ . It follows that  $s$  is a homomorphism on  $S_0$  and that  $S = s(S_0)$  is an open semigroup in  $G$ , and that  $SS^{-1} \cap Z = \{e\}$ . Thus  $G$  fails to have property T.
