# 0N THE ANNIHILATORS 0F THE SIMPLE SUBQU0TIENTS 0F THE PRINCIPAL SERIES $\left({ }^{( }\right)$ 

By A. JOSEPH

Abstract. - Let $g$ be a complex semisimple Lie algebra and denote by $U(g)$ its enveloping algebra. The main result of this paper (Th.5.2) gives a formula for the annihilators of the simple subquotients of the (spherical) principal series in terms of the annihilators of simple quotients of Verma modules. The proof involves a description of the principal series in terms (Th. 5.1) of products of the almost minimal primitive ideals of $\mathrm{U}(\mathrm{g})$. It was motivated by an attempt to find a method for distinguishing primitive ideals of $U(g)$. In particular for $g$ of type $A_{n}$ (Cartan notation) it is shown (Cor. 6.6) that a conjecture of Jantzen ( $[1], 5.9$ ) is equivalent to the simple subquotients of the principal series having distinct annihilators.

Index of notation. - Symbols frequently used in the text are given below in order of appearance.

## 1. Introduction

1.1. Let $\mathfrak{g}$ be a complex semisimple Lie algebra with triangular decomposition $\mathfrak{g}=\mathfrak{n}^{+} \oplus \mathfrak{h} \oplus \mathfrak{n}^{-}([8], 1.10 .14)$. Let $\mathrm{R} \subset \mathfrak{h}^{*}$ denote the set of non-zero roots, $\mathrm{R}^{+} \subset \mathbf{R}$ a system of positive roots, $B \subset R^{+}$a $Z$ basis for $R, \rho$ the half sum of the positive roots, W the Weyl group for the pair $\mathfrak{g}, \mathfrak{h}, \Sigma$ the subset of involutions of $W, s_{\alpha}$ the reflection corresponding to the root $\alpha$. Fix a Chevalley base for $\mathfrak{g}$, let $X_{\alpha}$ denote an element of weight $\alpha \in \mathrm{R}$ of this base, set $\mathrm{H}_{\alpha}=\left[\mathrm{X}_{\alpha}, \mathrm{X}_{-\alpha}\right]$ and $\alpha^{\nu}=2 \alpha /(\alpha, \alpha)$. Let $\mathrm{Q}(\mathrm{R})$ $[$ resp. $P(R)] \subset \mathfrak{h}^{*}$ denote the lattice of radicial (resp. integral) weights.
1.2. For each Noetherian C-algebra A, let $\mathbf{J}(A)$ (resp. Spec A, Prim A) denote the set of two-sided (resp. prime, primitive) ideals of A. For each C-Lie algebra $\mathfrak{a}$, let $\mathfrak{a}^{\wedge}$ denote the set of classes of finite dimensional irreducible representations of $\mathfrak{a}, U(\mathfrak{a})$ the enveloping algebra of $\mathfrak{a}, Z(\mathfrak{a})$ the centre of $U(\mathfrak{a})$. For each $\mathbf{C}$-vector space $V$, let $S(V)$ denote the symmetric algebra over V and $\mathrm{V}^{*}$ the dual of V .
1.3. The principal aim of this paper is the study of $\operatorname{Prim} U(g)$. In this recall [3], (3.2) that $\pi: I \mapsto I \cap Z(g)$ is a surjection of $\operatorname{Prim} U(g)$ onto $\operatorname{Max} Z(g)$. For each $\lambda \in \mathfrak{b}^{*}$, set $\mathbf{R}_{\lambda}=\left\{\alpha \in \mathbf{R}:\left(\lambda, \alpha^{2}\right) \in \mathbf{Z}\right\}, \mathbf{R}_{\lambda}^{+}=\mathbf{R}_{\lambda} \cap \mathbf{R}^{+}, \mathrm{B}_{\lambda} \subset \mathrm{R}_{\lambda}^{+}$a $\mathbf{Z}$ basis for $\mathrm{R}_{\lambda}, \mathrm{W}_{\lambda}$ the subgroup of W generated by the $s_{\alpha}: \alpha \in \mathrm{B}_{\lambda}$. Set

$$
\Sigma_{\lambda}=\Sigma \cap \mathbf{W}_{\lambda}, \quad \mathrm{D}_{\lambda}=\left\{w \in \mathrm{~W}: \quad w \mathrm{R}_{\lambda}^{+} \subset \mathrm{R}^{+}\right\}
$$

and $w_{\lambda}$ the unique element of $W_{\lambda}$ taking $B_{\lambda}$ to $-B_{\lambda}$. Call $\lambda$ dominant if $\left(\lambda, \alpha^{2}\right) \notin \mathbf{N}^{-}$, for all $\alpha \in \mathrm{R}^{+}$and regular if $(\lambda, \alpha) \neq 0$, for all $\alpha \in \mathrm{R}$. Let $\hat{\lambda}$ denote the orbit of $\lambda$ under W With $\mathfrak{b}:=\mathfrak{n}^{+} \oplus \mathfrak{h}$, let $\mathrm{E}_{\lambda}:=\mathbf{C} e_{\lambda}$ denote the one-dimensional $\mathfrak{b}$ module defined through $\mathbf{X} e_{\lambda}=0: X \in \mathfrak{n}^{+}, H e_{\lambda}=(H, \lambda) e_{\lambda}: H \in \mathfrak{h}$, and set $\mathrm{M}(\lambda):=\mathrm{U}(\mathfrak{g}) \otimes_{\mathrm{U}(b)} \mathrm{E}_{\lambda-\mathrm{p}}$, considered as a left $\mathrm{U}(\mathrm{g})$ module (cf. [8], Chaps. 5, 7). Recalling [8] (8.4.4), set $\mathrm{I}_{\hat{\lambda}}=$ Ann $\mathrm{M}(\lambda)$, $Z_{\hat{\lambda}}=\pi\left(I_{\hat{\lambda}}\right) . \quad$ Recalling [8] (7.1.11), let $\overline{M(\lambda)}$ denote the unique maximal submodule of $M(\lambda)$ and set $L(\lambda)=M(\lambda) / \overline{M(\lambda)}, I_{\lambda}=A n n L(\lambda)$ and $\mathbf{X}_{\hat{\lambda}}=\left\{I_{\mu}: \mu \in \hat{\lambda}\right\}$ considered as an ordered set (by inclusion of elements). (After Duflo [7], II, Thm. 1.)

Theorem. - For each $\hat{\lambda} \in \mathfrak{h}^{*} / \mathrm{W}$, one has $\mathbf{X}_{\hat{\lambda}}=\pi^{-1}\left(\mathrm{Z}_{\hat{\lambda}}\right)$.
This reduces the study of Prim $U(\mathfrak{g})$ to that of finite sets $\mathbf{X}_{\hat{\lambda}}: \lambda \in \mathfrak{h}^{*}$. Now the BorhoJantzen translation principle ([3], 2.12), shows that it suffices to determine $\mathbf{X}_{\hat{\lambda}}$ for $\lambda$ regular and then fixing $-\lambda \in \mathfrak{h}^{*}$ dominant and regular, the $\operatorname{map} \varphi_{\hat{\lambda}}: w \mapsto \mathrm{I}_{w \lambda}$ is a surjection of W onto $\pi^{-1}\left(Z_{\hat{\hat{\lambda}}}\right)$. Furthermore if we write $w=w_{1} w_{2}: w_{1} \in \mathrm{D}_{\lambda}, \mathrm{w}_{2} \in \mathrm{~W}_{\lambda}$, then by [10] (4.2), we have $\varphi_{\hat{\lambda}}(w)=\varphi_{\hat{\lambda}}\left(w_{2}\right)$. That is $\varphi_{\hat{\lambda}}$ factors through $W_{\lambda}$ giving a map $\varphi$ of $W_{\lambda}$ onto $\pi^{-1}\left(Z_{\hat{\lambda}}\right)$. The Borho-Jantzen translation principle for say $\lambda \in P(R)$ shows that $\varphi$ is in a natural sense independent of $\hat{\lambda}$ and suggests that in general $\varphi$ should only depend on $W_{\lambda}$. In [10], we indicated what this dependence might be by exhibiting a partition of $W_{\lambda}$ into cells so that each point in a given cell defines the same ideal. The main question that remains is to show that points in different cells define discinct ideals. Now this and the calculations of Borho-Jantzen on the low rank cases ([3], [4]), indicate that

[^0]Duflo's upper bound, namely card $\mathbf{X}_{\hat{\lambda}} \leqq \operatorname{card} \Sigma_{\lambda}([7]$, II, 2 ) should be very nearly saturated, that is one should expect to have card $\mathbf{X}_{\hat{\lambda}} \geqq \sqrt{\text { card } \mathbf{W}_{\lambda}}$. Let us see how such a bound might arise.
1.4. Let $u \mapsto^{t} u$ (resp. $u \mapsto \check{u}$ ) denote the involutory antiautomorphism of $\mathrm{U}(\mathfrak{g})$ defined by ${ }^{t} \mathrm{X}_{\alpha}=\mathrm{X}_{-\alpha}$, for all $\alpha \in \mathrm{R}$ and ${ }^{t} \mathrm{H}=\mathrm{H}$, for all $\mathrm{H} \in \mathfrak{h}$ (resp. $\check{\mathrm{X}}=-\mathrm{X}$, for all $\mathrm{X} \in \mathfrak{g}$ ). As noted by Duflo ([7], I, Modules de Verma), one has:

Lemma. - ${ }^{t} \mathrm{I}_{\lambda}=\mathrm{I}_{\lambda}$, for all $\lambda \in \mathfrak{h}$.
1.5. Identity $\mathrm{U}:=\mathrm{U}(\mathfrak{g}) \otimes \mathrm{U}(\mathfrak{g})$ canonically with $\mathrm{U}(\mathfrak{g} \oplus \mathfrak{g})$. Define the embedding $j: \mathfrak{g} \rightarrow \mathfrak{g} \oplus \mathfrak{g}$ through $j(\mathrm{X})=\left(\mathrm{X},-{ }^{t} \mathrm{X}\right)$, for all $\mathrm{X} \in \mathfrak{g}$ and set $\mathfrak{f}=j(\mathfrak{g})$ which is naturally isomorphic to $g$. In this $\mathfrak{f}^{\wedge}$ identifies canonically with $P(R) / W$ and we let $F_{\hat{v}}: v \in P(R)$ denote the unique simple finite dimensional $\mathfrak{f}$ module with extreme weight $v$. For each $\mu \in \mathfrak{h}^{*}$, let $\mathrm{F}_{\hat{v}}(\mu)$ denote the subspace of $\mathrm{F}_{\hat{v}}$ spanned by vectors of weight $\mu$. Given $\lambda$ $\mu \in \mathfrak{h}^{*}$, consider $(M(-\lambda) \otimes M(-\mu))^{*}$ as a $U$ module by transposition and let $L(\lambda, \mu)$ denote the subspace spanned by all $\mathfrak{f}$ finite elements (which is a $U$ submodule). As noted in say [6] (3.2), Frobenius reciprocity ([8], 5.5.7, 5.5.8) gives:

Lemma. - For all $\lambda, \mu \in \mathfrak{h}^{*}, \hat{v} \in \mathrm{P}(\mathrm{R}) / \mathrm{W}$, one has

$$
m t p(\hat{v}, \mathrm{~L}(\lambda, \mu))=\operatorname{dim} \mathrm{F}_{\hat{v}}(\lambda-\mu)
$$

In particular $L(\lambda, \mu)=0$, unless $\lambda-\mu \in P(R)$. Again if $\lambda-\mu \in \hat{v}$, then $\hat{v}$ occurs with multiplicity one in $L(\lambda, \mu)$ and we denote this component by $L^{0}(\lambda, \mu)$. Let $V(\lambda, \mu)$ denote the unique simple quotient of $\mathrm{UL}^{0}(\lambda, \mu)$ admitting a $\mathfrak{f}$ submodule of type $\hat{\mathbf{v}}$. These modules which are said to belong to the principal series have been systematically studied. The results are reviewed in [6].
1.6. After Duflo ([7], Prop. 7), one has:

Proposition. - For all $\lambda, \mu \in \mathfrak{h}^{*}: \lambda-\mu \in \mathrm{P}(\mathrm{R})$, there exist $\lambda^{\prime} \in \hat{\lambda}, \mu^{\prime} \in \hat{\mu}$ such that

$$
\operatorname{Ann} V(-\mu,-\lambda)=\check{I}_{\mu^{\prime}} \otimes \mathrm{U}(\mathfrak{g})+\mathrm{U}(\mathfrak{g}) \otimes \check{\mathrm{I}}_{\lambda^{\prime}}
$$

Consider the special case when $\lambda$ is regular and $\mu \in \hat{\lambda}$. Then $\mu=w \lambda$, for some $w \in \mathrm{~W}_{\lambda}$ and through the isomorphisms of the $\mathrm{V}(-w \lambda,-\lambda)([6], 4.1)$, we can assume $-\lambda$ fixed and say dominant. It follows that if the (non-isomorphic) U modules $\mathrm{V}(-w \lambda,-\lambda): w \in \mathrm{~W}_{\lambda}$, have distinct annihilators, then $\left(\operatorname{card} \mathbf{X}_{\hat{\lambda}}\right)^{2} \geqq \operatorname{card} \mathrm{~W}_{\lambda}$. Unfortunately we shall see that the former assertion is generally false; yet it is obviously of interest to determine a precise formula for Ann $\mathrm{V}(-w \lambda,-\lambda)$. Our main result (Th. 5.2) shows that under the above hypotheses we can take $\mu^{\prime}=w_{\lambda} w \lambda, \lambda^{\prime}=w_{\lambda} w^{-1} \lambda$ (recall that the $\mathrm{I}_{w^{\prime} \lambda}: w^{\prime} \in \mathrm{W}_{\lambda}$ are not all distinct). For $W_{\lambda}$ simple of type $A_{n}$ (Cartan notation) it is further shown (Sect. 6) that the Ann $\mathrm{V}(-w \lambda,-\lambda): w \in \mathrm{~W}_{\lambda}$, are pairwise distinct if and only if card $\mathbf{X}_{\hat{\lambda}}=\operatorname{card} \Sigma_{\lambda}$. In this we recall that if $\lambda \in P(R)$, then Borho and Jantzen ([3], [4]) have shown that the former equality holds up to $n=5$. Perhaps the most interesting results are those of Section 4 which give remarkable sum and product formulae for the "almost minimal" primitive ideals which generalize [8] (7.8.12) and [7] (Prop. 12).
1.7. The proofs we give are entirely algebraic; but depend on results on complex Lie groups, so we have preferred to simply assume $\mathfrak{g}$ defined over $\mathbf{C}$. The use of the principal antiautomorphism $U$ is not strictly necessary; but it seemed preferable to stick to the notational conventions of ([5], [6], [7]) where logically possible. I should like to thank M. Duflo for many discussions concerning these papers. Part of this work was done during a stay at the Sonderforschungsbereich, Bonn and I should like to thank W. Borho for a preview of his recent results with Jantzen concerning $\mathbf{X}_{\hat{\lambda}}$.

## 2. Two order relations on the Weyl group

2.1. For each $\lambda \in \mathfrak{h}^{*}, w \in W_{\lambda}$ set

$$
\mathrm{S}_{\lambda}(w)=w^{-1} \mathrm{R}_{\lambda}^{-} \cap \mathrm{R}_{\lambda}^{+}, \quad l_{\lambda}(w)=\operatorname{card} \mathrm{S}_{\lambda}(w), \quad \tau_{\lambda}(w)=\mathrm{S}_{\lambda}(w) \cap \mathrm{B}_{\lambda}
$$

Recall that $l_{\lambda}(w)$ is just the least number of ways of writing $w$ as a product of the generating reflections $\left\{s_{\alpha}: \alpha \in \boldsymbol{B}_{\lambda}\right\}$ and such a product is called a reduced decomposition for $w$. The group $\mathrm{W}_{\lambda}$ admits an order relation $\leqq$ defined as follows. Let

$$
w=s_{1} s_{2} \ldots s_{n}, \quad s_{i}=s_{\alpha_{i}}, \quad \alpha_{i} \in \mathrm{~B}_{\lambda}
$$

be a reduced decomposition for $w$. Then $w^{\prime} \leqq w$ iff we can write $w^{\prime}=s_{i_{1}} s_{i_{2}} \ldots s_{i_{m}}$, where $1 \leqq i_{1}<i_{2}<\ldots<i_{m} \leqq n$. It is easy to show that the expression for $w^{\prime}$ can be assumed reduced and then by [8] (7.7.4), this is the same order relation as that defined in [8] (7.7.3).

Lemma. - For all $w, w^{\prime} \in \mathrm{W}_{\lambda}$,
(i) $w \leqq w^{\prime} \Leftrightarrow w^{-1} \leqq w^{-1}$;
(ii) $w \leqq w^{\prime} \Leftrightarrow w_{\lambda} w \geqq w_{\lambda} w^{\prime}$.
(i) is clear. (ii) follows from [8] (7.7.3) and the relation $l_{\lambda}\left(w_{\lambda}\right)=l_{\lambda}\left(w_{\lambda} w\right)+l_{\lambda}(w)$ (cf. [10], 3.1).
2.2. Recall that the map $\mathrm{S}_{\lambda}: w \mapsto \mathrm{~S}_{\lambda}(w)$ of $\mathrm{W}_{\lambda}$ into $\mathbf{P}\left(\mathrm{R}_{\lambda}^{+}\right)$is injective ([10], 3.9). The group $\mathrm{W}_{\lambda}$ admits an order relation $\subseteq$, defined through $w^{\prime} \subseteq w$ iff $\mathrm{S}_{\lambda}\left(w^{\prime}\right) \subseteq \mathrm{S}_{\lambda}(w)$. By say [10] (3.1), we have:

Lemma. - For each $w \in \mathrm{~W}_{\lambda}, \alpha \in \tau_{\lambda}\left(w^{-1}\right)$ one has $s_{\alpha} w \subseteq w . \quad$ Moreover $\left\{s_{\alpha} w: \alpha \in \tau_{\lambda}\left(w^{-1}\right)\right\}$ is the set of all maximal elements of $\mathrm{W}_{\lambda}$ strictly less than $w($ for $\subseteq)$.

In particular $w \subseteq w^{\prime}$ implies $w \leqq w^{\prime}$.
2.3. Let $\alpha, \beta$ be distinct elements of $B_{\lambda}$ and suppose that $(\alpha, \alpha) \leqq(\beta, \beta)$. Then $\left(\alpha^{2}, \beta\right)=-k$, with $k=0,1,2$, or 3 . One has

$$
s_{\alpha} s_{\beta}=s_{\beta} s_{\alpha}: \quad k=0, \quad s_{\alpha} s_{\beta} s_{\alpha}=s_{\beta} s_{\alpha} s_{\beta}: \quad k=1, \quad\left(s_{\alpha} s_{\beta}\right)^{k}=\left(s_{\beta} s_{\alpha}\right)^{k}: \quad k=2,3
$$

For the appropriate $k$ we call this a pair relation (for the pair $\alpha, \beta$ ). Recall that $W_{\lambda}$ is generated by the involutions $s_{\alpha}: \alpha \in \mathrm{B}_{\lambda}$ satisfying all possible pair relations.

Lemma. - Let $w \in \mathrm{~W}_{\lambda}$. Any two reduced decompositions of $w$ can be transformed into one another through just the pair relations (i. e. without using the identities $\left.s_{\alpha}^{2}=1: \alpha \in B_{\lambda}\right)$.

```
    4e série - tome 10 - 1977 - No 4
```

The proof is by induction on $l_{\lambda}(w)$. If $l_{\lambda}(w)=0$, then $w=1$ and the assertion is trivial. Suppose in the respective reduced decompositions we have $w=s_{\alpha} w_{1}$, $w=s_{\beta} w_{2}: \alpha, \beta \in \mathrm{B}_{\lambda}$. We can assume $\alpha \neq \beta$ and then by say the first part of [10] (3.6), we have $\alpha \in \tau_{\lambda}\left(w_{2}^{-1}\right), \beta \in \tau_{\lambda}\left(w_{1}^{-1}\right)$. By the induction hypothesis and 2.2 , we can write $w_{1}=s_{\beta} w_{3}, w_{2}=s_{\alpha} w_{4}$ up to pair relations. If $k=0$, then $w_{3}=w_{4}$ and the assertion holds in this case. Otherwise by [10] (3.6), we have as above $w_{3}=s_{\alpha} w_{5}, w_{4}=s_{\beta} w_{6}$, up to pair relations. This process eventually gives the required assertion.
Remark. - This elementary (but for us important) fact is for example noted in [17] (Lemma $83 a$ ) where its proof is left as an exercise.

## 3. The principal series

3.0. Fix $\lambda, \mu \in \mathfrak{h}^{*}$, with $\lambda-\mu \in \mathrm{P}(\mathrm{R})$. We start by summarizing some classical results on the modules $\mathrm{M}(\lambda), \mathrm{L}(\lambda, \mu), \mathrm{V}(\lambda, \mu)$.
3.1. Theorem. - (cf. [6], I, 4):
(i) $\mathrm{V}(\lambda, \mu)$ is isomorphic to $\mathrm{V}\left(\lambda^{\prime}, \mu^{\prime}\right)$ iff $\lambda^{\prime}=w \lambda, \mu^{\prime}=w \mu$, for some $w \in \mathrm{~W}$;
(ii) $\mathrm{UL}^{0}(\lambda, \mu)=\mathrm{L}(\lambda, \mu)$, if $\lambda$ or $\mu$ is dominant;
(iii) $\mathrm{UL}^{0}(\lambda, \mu)=\mathrm{V}(\lambda, \mu)$, if $-\lambda$ or $-\mu$ is dominant;
(iv) $\mathrm{L}(\lambda, \mu)$ has finite length as a U module, its simple factors are amongst the $V\left(\lambda^{\prime}, \mu^{\prime}\right): \lambda^{\prime} \in \hat{\lambda}, \mu^{\prime} \in \hat{\mu}$, with $V(\lambda, \mu)$ occurring exactly once.
3.2. Theorem. - (cf. [7], [8], 7.6.23. Suppose $-\lambda \in \mathfrak{b}^{*}$ dominant and regular. For each pair $w, w^{\prime} \in \mathrm{W}_{\lambda}, \mathrm{M}\left(w^{\prime} \lambda\right)\left[r e s p . \mathrm{L}\left(w^{\prime} \lambda\right)\right]$ is a submodule (resp. subquotient) of $\mathrm{M}(w \lambda)$ iff $w \geqq w^{\prime}$.
3.3. Consider $\operatorname{Hom}_{\mathbf{c}}(\mathrm{M}(\mu), \mathrm{M}(\lambda))$ as a U module through $((a \otimes b) . \mathrm{T}) m=\left({ }^{\mathrm{t}} \hat{\mathrm{a}} \mathrm{T} \check{b}\right) m$, for all $\mathrm{T} \in \operatorname{Hom}_{\mathrm{c}}(\mathrm{M}(\mu), \mathrm{M}(\lambda)), a, b \in \mathrm{U}(\mathrm{g}), m \in \mathrm{M}(\mu)$. Let $\mathrm{L}(\mathrm{M}(\mu), \mathrm{M}(\lambda))$ denote the subspace of $\operatorname{Hom}_{\mathbf{C}}(\mathbf{M}(\mu), M(\lambda))$ spanned by all $\mathfrak{f}$ finite elements (which is a $U$ submodule).
Suppose $M(\lambda)$ is a submodule of $M(\mu)$ and suppose given $I \in \mathbf{J}\left(U(g) / I_{\hat{\mu}}\right)$ satisfying IM $(\mu) \subset M(\lambda)$. Then the representation of $U(g)$ in $M(\mu)$ defines an embedding of $I$ in $L(M(\mu), M(\lambda))$.
3.4. Let $P$ denote the projection of $U(\mathfrak{g})$ onto $U(\mathfrak{h})$ [which identifies with $S(\mathfrak{h})$ ] defined by the decomposition $U(\mathfrak{g})=\mathbf{U}(\mathfrak{h}) \oplus\left(\mathfrak{n}^{-} \mathrm{U}(\mathfrak{g})+\mathbf{U}(\mathfrak{g}) \mathfrak{n}^{+}\right)$. For each $\left.\lambda \in \mathfrak{b}\right)^{*}$, define $P_{\lambda}: U(g) \rightarrow \mathbf{C}$, through $P_{\lambda}(a)=(P(a), \lambda-\rho)$. Given $I \in J(U(g))$, set

$$
\mathscr{V}(\mathrm{I})=\left\{\lambda \in \mathfrak{h}^{*}: \quad \mathrm{P}_{\lambda+\mathrm{p}}(a)=0, \text { for all } a \in \mathrm{I}\right\} .
$$

Define a bilinear form on $\mathrm{M}(\lambda)$ through $\left.\left\langle a e_{\mu-\rho}, b e_{\alpha-\rho}\right\rangle=\mathrm{P}_{\lambda}{ }^{( }{ }^{t} a b\right)$ (which we recall is $\mathfrak{f}$ invariant and determined up to a scalar by this latter property). Identify $\mathrm{E}_{\mu-\rho}$ (resp. $\mathrm{E}_{\lambda-\rho}$ ) with the corresponding weight space in $\mathrm{M}(\mu)$ [resp. $\mathrm{M}(\lambda)$ ]. Given $T \in L(M(\mu), M(\lambda))$ define

$$
\psi_{T} \in \operatorname{Hom}_{\mathbf{c}}\left(\mathrm{U}, \operatorname{Hom}_{\mathbf{c}}\left(\mathrm{E}_{\mu-\rho}, \mathrm{E}_{\lambda-\rho}\right)\right)
$$

through

$$
\left\langle e_{\lambda-\rho}, \psi_{\mathrm{T}}(a \otimes b) e_{\mu-\rho}\right\rangle=\left\langle a e_{\lambda-\rho}, \mathrm{T} b e_{\mu-\rho}\right\rangle,
$$

for all $a, b \in \mathrm{U}(\mathrm{g})$. After Conze-Berline, Duflo ([5], 5.3, 5.5), we have
annales scientifiques de l'école normale supérieure

Proposition. - The map $\psi: \mathrm{T} \mapsto \psi_{\mathrm{T}}$ is a U module homomorphism of $\mathrm{L}(\mathrm{M}(\mu), \mathrm{M}(\lambda))$ into $\mathrm{L}(-\lambda,-\mu)$. Furthermore:
(i) $\operatorname{ker} \psi=\{\mathrm{T} \in \mathrm{L}(\mathrm{M}(\mu), \mathrm{M}(\lambda))$ such that $\mathrm{TM}(\mu) \subset \overline{\mathrm{M}(\lambda)}\}$;
(ii) given $\mathrm{M}(\lambda)$ simple, then $\psi$ is an isomorphism.

Remark. - Assume $-\lambda \in \mathfrak{b}^{*}$ dominant. Then as noted in [5] (6.3), it follows from 3.1 (ii), 3.2, 3.4 (ii) that $\psi$ induces a $U$ module isomorphism of $U(\mathfrak{g}) / I_{\hat{\lambda}}$ onto $\mathrm{L}(-\lambda,-\lambda)$ and we identify these modules.
3.5. We require the following refinement of 3.4. Take $-\lambda \in \mathfrak{b}^{*}$ dominant and $w \in \mathrm{~W}_{\lambda}$. Suppose we have $\mathbf{J} \in \mathbf{J}\left(\mathrm{U}(\mathrm{g}) / \mathrm{I}_{\hat{\hat{\lambda}}}\right)$ satisfying $m t p\left((\lambda-w \lambda)^{\wedge}, \mathbf{J}\right)=1, \mathrm{JM}\left(w_{\lambda} \lambda\right)=\mathrm{M}\left(w_{\lambda} w \lambda\right)$ and generated as a $U$ module by its component of type $(\lambda-w \lambda)^{\wedge}$.

## Theorem:

(i) given J 丮 $\mathrm{K} \in \mathbf{J}\left(\mathrm{U}(\mathrm{g}) / \mathrm{I}_{\hat{\lambda}}\right)$, then $\mathrm{KM}\left(w_{\lambda} \lambda\right) \subset \overline{\mathrm{M}\left(w_{\lambda} w \lambda\right)}$;
(ii) if $\mathrm{J} \nsubseteq \mathrm{I}_{w_{\lambda} w \lambda}$, then $\left(\mathrm{J}+\mathrm{I}_{w_{\lambda} w \lambda}\right) / \mathrm{I}_{w_{\lambda} w \lambda}$ is isomorphic to $\mathrm{V}(-w \lambda,-\lambda)$ as a U module.

Consider J as a submodule of $\mathrm{L}\left(\mathrm{M}\left(w_{\lambda} \lambda\right), \mathrm{M}\left(w_{\lambda} w \lambda\right)\right)$ and restrict $\psi$ defined in 3.4 to J. Then

$$
\begin{array}{rll}
\operatorname{ker} \psi & =\{a \in \mathrm{~J}: & \left.a \mathrm{M}\left(w_{\lambda} \lambda\right) \subset \overline{\mathrm{M}\left(w_{\lambda} w \lambda\right)}\right\} \\
& \subset\{a \in \mathrm{~J}: & \left.a \mathrm{M}\left(w_{\lambda} w \lambda\right) \subset \overline{\mathrm{M}\left(w_{\lambda} w \lambda\right)}\right\} \subset \mathrm{I}_{w_{\lambda} w \lambda} .
\end{array}
$$

Through the hypothesis $\mathrm{JM}\left(w_{\lambda} \lambda\right)=\mathrm{M}\left(w_{\lambda} w \lambda\right)$, we have $\operatorname{Im} \psi \neq 0$ and since J is generated as a U module by a $\mathfrak{f}$ submodule of type $\left(w_{\lambda} \lambda-w_{\lambda} w \lambda\right)^{\wedge}$ it follows that $\operatorname{Im} \psi=\mathrm{UL}^{0}\left(-w_{\lambda} w \lambda,-w_{\lambda} \lambda\right)$. Yet $w_{\lambda} \lambda$ is dominant and so by 3.1 (i) and 3.1 (iii), $\operatorname{Im} \psi$ is isomorphic to the simple U module $\mathrm{V}(-w \lambda,-\lambda)$.
If $\mathrm{K} \mp \mathrm{J}$, then $\psi(\mathrm{K})$ can have no component of type $(\lambda-w \lambda)^{\wedge}$ and so is a strict submodule of $\mathrm{V}(-w \lambda,-\lambda)$. By 3.4 (i), this gives (i).

If $\mathbf{J} \ddagger \mathbf{I}_{w_{\lambda} w \lambda}$, then $\operatorname{ker} \psi=\mathbf{J} \cap \mathbf{I}_{w_{\lambda} w \lambda}$ by the simplicity of $\operatorname{Im} \psi$. This gives (ii).
3.6. Fix $-\lambda \in \mathfrak{b}^{*}$ dominant and regular. By [7] (Cor. 2 to Prop. 10), $\left\{\mathrm{I}_{s_{\alpha}}: \alpha \in \mathrm{B}_{\lambda}\right\}$, is the set of smallest primitive ideals of $\mathrm{U}(\mathrm{g})$ strictly containing the minimal primitive ideal $\mathrm{I}_{\lambda}=\mathrm{I}_{\hat{\lambda}}$. We call then the almost minimal primitive ideals. Set $\mathrm{I}_{\alpha}:=\mathrm{I}_{s_{\alpha}} / \mathrm{I}_{\lambda}$. Take $w \in W_{\lambda}$ and recall 3.2. The injection $\mathrm{M}(\lambda) \leftrightarrows \mathrm{M}(w \lambda)$ defines by transposition a $U$ module homomorphism $\theta_{w}$ of $L(-\lambda,-w \lambda)$ into $L(-\lambda,-\lambda)$ and by restriction a $U$ module homomorphism $\Theta_{w}$ of $L(M(w \lambda), M(\lambda))$ into $L(M(\lambda), M(\lambda))$. Define $\psi$ (resp. $\psi^{\prime}$ ) as in 3.4 with $\mu=w \lambda$ (resp. $\mu=\lambda$ ). This gives the commutative diagram

Since $-\lambda$ is dominant, $M(\lambda)$ is simple and so by 3.4 (ii) $\psi, \psi^{\prime}$ are isomorphisms.
Set $\mathrm{I}=\mathrm{Ann} \mathbf{M}(w \lambda) / \mathrm{M}(\lambda)$ [computed in $\mathrm{U}(\mathrm{g})$ ] and define $\operatorname{Dim}$ as in [15] (2.1). It follows exactly as in 4.7 that $\operatorname{Dim} U(g) / I=\operatorname{card} R-2=\operatorname{Dim} U(g) / I_{\lambda}-2$ and so $\mathrm{I} / \mathrm{I}_{\lambda} \neq 0$. Recalling that $\operatorname{Ann} \mathrm{M}(w \lambda)=\operatorname{Ann} \mathrm{M}(\lambda)$ and 3.3, it follows that the repre-

```

```

sentation of $U(\mathfrak{g})$ in $M(w \lambda)$ defines an embedding of $\mathrm{I} / \mathrm{I}_{\lambda}$ in $\mathrm{L}(\mathrm{M}(w \lambda), \mathrm{M}(\lambda))$ and the restriction of $\Theta_{w}$ to $I / I_{\lambda}$ is injective. Hence $\theta_{w} \neq 0$.

Theorem. - For all $w \in \mathrm{~W}_{\lambda}, \alpha \in \mathrm{B}_{\lambda}$ :
(i) there exists a U module monomorphism $\theta_{w}^{\prime}\left(\right.$ resp. $\left.\theta_{w}^{\prime \prime}\right)$ of $\mathrm{L}(-w \lambda,-\lambda)[$ resp. $\mathrm{L}(-\lambda,-w \lambda)]$ into $\mathrm{L}(-\lambda,-\lambda)$;
(ii) $m t p\left(\mathrm{~V}\left(-w_{\lambda} \lambda,-\lambda\right), \mathrm{L}(-w \lambda,-\lambda)\right)=m t p\left(\mathrm{~V}\left(-w_{\lambda} \lambda,-\lambda\right), \mathrm{L}(-\lambda,-w \lambda)\right)=1$;
(iii) any non-zero U module homomorphism of $\mathrm{L}(-w \lambda,-\lambda)[\operatorname{resp} . \mathrm{L}(-\lambda,-w \lambda)]$ into $\mathrm{L}(-\lambda,-\lambda)$ is injective and coincides up to a scalar with $\theta_{w}^{\prime}$ (resp. $\left.\theta_{w}^{\prime \prime}\right)$. In particular we can take $\theta_{w}^{\prime \prime}$ to be $\theta_{w}$;
(iv) $\mathrm{L}\left(-\lambda,-s_{\alpha} \lambda\right)=\mathrm{L}\left(-s_{\alpha} \lambda,-\lambda\right)=\mathrm{I}_{\alpha}$, considered as submodules of $\mathrm{L}(-\lambda,-\lambda)$.

The first part of (i) follows on taking a reduced decomposition of $w$ and repeated application of the first part of [7], Lemma 5. Consider $L(-w \lambda,-\lambda)$ as a submodule of $\mathrm{U}(\mathfrak{g}) / \mathrm{I}_{\lambda}$. Then as noted in [7] (Prop. 9), ${ }^{t} \mathrm{~L}(-w \lambda,-\lambda)$ is isomorphic as a U module to $\mathrm{L}(-\lambda,-w \lambda)$. This proves the second part of (i).

The proofs of the two parts of (ii) and (iii) are similar and we consider only $L(-w \lambda,-\lambda)$. By [7] (Prop. 4), $m t p\left(\mathrm{~V}\left(-w_{\lambda} \lambda,-\lambda\right), \mathrm{L}(-w \lambda,-\lambda)\right) \geqq 1$. By (i) it suffices to reverse this inequality in the case when $w=1$. By (i) and 3.1 (iii), $\mathrm{V}\left(-w_{\lambda} \lambda,-\lambda\right)$ identifies with a submodule of $L(-\lambda,-\lambda)$ and so by 3.4 , there exists $I \in J(U(\mathfrak{g}))$ such that $\mathrm{I} / \mathrm{I}_{\lambda}=\mathrm{V}\left(-w_{\lambda} \lambda,-\lambda\right)$ up to isomorphism. Yet $\mathrm{I}_{\lambda}$ is prime (in fact completely prime) and so by [2] (3.6), one has $\operatorname{Dim} U(g) / I<\operatorname{Dim} U(g) / I_{\lambda}$. It follows from say [2] (5.5), that $U(g) / I$ is too small to admit a subquotient isomorphic to $I / I_{\lambda}$. This proves (ii).

We have seen that $\mathrm{L}(-\lambda,-\lambda)$ admits a submodule V isomorphic to $\mathrm{V}\left(-w_{\lambda} \lambda,-\lambda\right)$. By [7], Remark preceeding Proposition 12, $\mathrm{L}(-\lambda,-\lambda)$ admits a unique simple submodule which must hence coincide with V. By (i), $\mathrm{L}(-w \lambda,-\lambda)$ admits just one simple submodule and this is necessarily isomorphic to $V$. Now let $\theta$ be a $U$ module homomorphism of $L(-w \lambda,-\lambda)$ into $L(-\lambda,-\lambda)$. If $\operatorname{Im} \theta \neq 0$, then it contains $V$. If $\operatorname{ker} \theta \neq 0$, it contains a submodule isomorphic to $V$. Then (iii) follows from (ii). (iv) follows from [7] (Lemme 5 and Proposition 10).

Remarks. - The assertions corresponding to (ii) and (iii) for Verma modules are wellknown [8] (7.6.6), and the proof of (ii) was inspired by the improved Borho-Jantzen proof of [8] (7.6.6). The way to obtain (iii) from (i) and (ii) was pointed out to me by Duflo.

### 3.7. Hypotheses 3.6

Corollary. - For each $w \in \mathrm{~W}_{\lambda}$, one has ${ }^{t} \mathrm{~L}(-w \lambda,-\lambda)=\mathrm{L}(-\lambda,-w \lambda)$, considered as submodules of $\mathrm{U}(\mathrm{g}) / \mathrm{I}_{\lambda}$.

As remarked in [7] (Prop. 9), the above are isomorphic as $U$ submodules of $U(g) / I_{\lambda}$. Hence the assertion follows from 3.4 and 3.6 (iii).
3.8. Notation and Hypotheses 3.6. Consider $L(-\lambda,-w \lambda)$ as a two-sided ideal of $U(g) / I_{\lambda}$.

Proposition. - For all $w, w^{\prime} \in \mathrm{W}_{\lambda}$ :
(i) $\operatorname{ker} \Theta_{w}=0$;
(ii) $\mathrm{L}(-\lambda,-w \lambda) \supset \operatorname{Ann} \mathrm{M}(w \lambda) / \mathrm{M}(\lambda)\left[\right.$ computed in $\left.\mathrm{U}(\mathrm{g}) / \mathrm{I}_{\lambda}\right]$;
(iii) $\mathrm{L}(-\lambda,-w \lambda) \supset \mathrm{L}\left(-\lambda,-w^{\prime} \lambda\right)$, if $w \leqq w^{\prime}$.

Through the commutative diagram defined in 3.6 , we obtain (i) from 3.6 (iii) and (ii) from 3.3, 3.4 and 3.6 (iii). Given $w^{\prime} \geqq w$, we obtain from 3.2 the injections $\mathrm{M}(\lambda) \subseteq \mathrm{M}(w \lambda) \subsetneq \mathrm{M}\left(w^{\prime} \lambda\right)$ and hence by restriction the homomorphisms

$$
\mathrm{L}\left(\mathrm{M}\left(w^{\prime} \lambda\right), \mathrm{M}(\lambda)\right) \xrightarrow{\ominus} \mathrm{L}(\mathrm{M}(w \lambda), \mathrm{M}(\lambda))
$$

and

$$
L(M(w \lambda), M(\lambda)) \xrightarrow{\boldsymbol{\theta}_{\omega}} L(M(\lambda), M(\lambda)) .
$$

Clearly $\Theta_{w} \Theta=\Theta_{w^{\prime}}$ and so $\Theta$ is injective by (i). This gives (iii).
3.9. Fix $-\lambda \in \mathfrak{b}^{*}$ dominant and regular. For each $w \in W_{\lambda}$, set

$$
\begin{array}{ll}
\operatorname{LAnn} \mathrm{V}(-w \lambda,-\lambda)=\{a \in \mathrm{U}(\mathrm{~g}): & (\check{a} \otimes 1) \mathrm{V}(-w \lambda,-\lambda)=0, \\
\operatorname{RAnn} \mathrm{~V}(-w \lambda,-\lambda)=\{a \in \mathrm{U}(\mathrm{~g}): & (1 \otimes \check{a}) \mathrm{V}(-w \lambda,-\lambda)=0\} .
\end{array}
$$

In the notation of 1.6 taking $\mu=w \lambda$, we have LAnn $V(-w \lambda,-\lambda)=\mathrm{I}_{\mu^{\prime}}$ and RAnn $V(-w \lambda,-\lambda)=\mathrm{I}_{\lambda^{\prime}}$. We set $\mu^{\prime}=w_{1} \lambda, \lambda^{\prime}=w_{2} \lambda: w_{1}, w_{2} \in \mathrm{~W}_{\lambda}$.

Proposition. - For all $w \in \mathrm{~W}_{\lambda}$ :
(i) $w_{1} \leqq w_{\lambda} w$;
(ii) $\operatorname{LAnn} \mathrm{V}(-w \lambda,-\lambda)=\operatorname{RAnn} \mathrm{V}\left(-w^{-1} \lambda,-\lambda\right)$;
(iii) $\left\{\operatorname{LAnn} V(-\sigma \lambda,-\lambda): \sigma \in \Sigma_{\lambda}\right\}=\mathbf{X}_{\hat{\lambda}}$ (Duflo [7]).

Recall the argument of [7] (Prop. 7). By 3.1 (i), (iii), $\mathrm{V}(-w \lambda,-\lambda)$ identifies with a submodule of $L\left(-w_{\lambda} w \lambda,-w_{\lambda} \lambda\right)$ and then its orthogonal M in $\mathrm{M}\left(w_{\lambda} w \lambda\right) \otimes \mathrm{M}\left(w_{\lambda} \lambda\right)$ is a proper submodule of the latter. Let $\mathrm{M}^{\prime}$ be a submodule (not necessarily unique) of $\mathrm{M}\left(w_{\lambda} w \lambda\right) \otimes \mathrm{M}\left(w_{\lambda} \lambda\right)$ containing M such that $\mathrm{M}^{\prime} / \mathrm{M}$ is simple. By $3.2, \mathrm{M}^{\prime} / \mathrm{M}$ is isomorphic to $\mathrm{L}\left(w_{1} \lambda\right) \otimes \mathrm{L}\left(w_{2} \lambda\right)$, for some $w_{1}, w_{2} \in \mathrm{~W}_{\lambda}$ with $w_{1} \leqq w_{\lambda} w$. By duality this gives (i). (ii) follows from 1.4, 3.1 (i), 3.1 (ii) and 3.7. (iii) is just [7] (Prop. 9).
Remark. - By (ii), (iii) one has card $\mathbf{X}_{\hat{\imath}}=\operatorname{card} \Sigma_{\lambda}$, iff the Ann $\mathrm{V}(-\sigma \lambda,-\lambda): \sigma \in \Sigma_{\lambda}$ are pairwise distinct (cf. 1.6 and 6.6).

## 4. The almost minimal primitive ideals

4.0. In this section we fix $-\lambda \in \mathfrak{b}^{*}$ dominant and regular. For all $\alpha \in B_{\lambda}$, we set $I_{\alpha}:=I_{s_{\alpha}} / I_{\lambda}$ and $I_{\alpha}^{*}:=I_{\omega_{\lambda} s_{\alpha} \alpha} / I_{\lambda}$ (this latter notation is motivated by a conjecture of BorhoJantzen [3], 2.19). For all $\mathrm{B}^{\prime} \subset \mathrm{B}_{\lambda}$, we set $\mathrm{I}_{\mathbf{B}^{\prime}}=\mathrm{I}_{\mathbf{w}_{B^{\prime}} / \mathrm{I}_{\lambda}}$.
4.1. Define a map $\tau: \mathbf{X}_{\hat{\lambda}} \rightarrow \mathbf{P}\left(B_{\lambda}\right)$, through $\tau\left(I_{w \lambda}\right)=\left\{\alpha \in B_{\lambda}: I_{w \lambda} \supset I_{s_{\alpha} \lambda}\right\}$. BorhoJantzen and Duflo established independantly [cf. [10], 4.4 (ii)] that

Theorem. $-\tau\left(\mathrm{I}_{w \lambda}\right)=\tau_{\lambda}(w)$, for all $w \in \mathrm{~W}_{\lambda}$.

$$
4^{\circ} \text { série - tome } 10-1977-\mathrm{N}^{\circ} 4
$$

4.2. Corollary. - For all $w \in \mathrm{~W}_{\lambda}, \alpha \in \mathrm{B}_{\lambda}$ one has $\mathrm{I}_{\alpha} \mathrm{M}(w \lambda)=\mathrm{M}(w \lambda)$ iff $\alpha \notin \tau_{\lambda}(w)$ :

$$
\mathbf{I}_{\alpha} \mathbf{M}(w \lambda) \subset \overline{\mathbf{M}\left(w_{i} \lambda\right)} \Leftrightarrow \mathrm{I}_{\alpha} \subset \mathrm{I}_{w \lambda} / \mathrm{I}_{\lambda} \Leftrightarrow \mathbf{I}_{s_{\alpha} \lambda} \subset \mathrm{I}_{w \lambda} \Leftrightarrow \alpha \in \tau_{\lambda}(w),
$$

by 4.1.
4.3. Lemma. - Suppose $w \in \mathrm{~W}_{\lambda}$. Then LAnn $\mathrm{V}(-w \lambda,-\lambda)=\mathrm{I}_{w_{\lambda} \lambda}$, iff $w=1$.

In the identification $U(\mathfrak{g}) / I_{\lambda}=L(-\lambda,-\lambda)$, the image of 1 is the unique trivial $\mathfrak{f}$ submodule of $\mathrm{L}(-\lambda,-\lambda)$. Then recalling 3.1 (ii) we have $\mathrm{V}(-\lambda,-\lambda)=\mathrm{U}(\mathrm{g}) / \mathrm{I}_{w_{\lambda} \lambda}$, which gives sufficiency. Necessity follows from 2.9 (i).
4.4. Lemma. - For each $\mathrm{B}^{\prime} \subset \mathrm{B}_{\lambda}, \alpha \in \mathrm{B}^{\prime}$, one has:
(i) $\mathrm{I}_{\mathrm{B}_{\lambda}}^{2}=\mathrm{I}_{\mathrm{B}_{\lambda}}$;
(ii) $\mathrm{I}_{\alpha}+\mathrm{I}_{\alpha}^{*}=\mathrm{I}_{\mathrm{B}_{\alpha}}$;
(iii) $\left(\mathrm{I}_{\alpha}^{*}+\mathrm{I}_{\mathrm{B}^{\prime}}\right) / \mathrm{I}_{\alpha}^{*}$ [and hence $\left.\mathrm{I}_{\mathbf{B}^{\prime}} /\left(\mathrm{I}_{\alpha}^{*} \cap \mathrm{I}_{\mathbf{B}^{\prime}}\right)\right]$ is isomorphic to the simple U module $\mathrm{V}\left(-s_{\alpha} \lambda,-\lambda\right)$;
(iv) $\mathrm{I}_{\alpha}^{2}=\mathrm{I}_{\alpha}$.

Suppose (i) is false. Then by 3.1 (iv) and 3.4 , there exists $\mathbf{J} \in \mathbf{J}\left(\mathrm{U}(\mathrm{g}) / \mathrm{I}_{\lambda}\right)$ containing $\mathrm{I}_{\mathrm{B}_{\lambda}}^{2}$ such that $\mathrm{I}_{\mathrm{B}_{\lambda} / J}$ is isomorphic to $\mathrm{V}(-w \lambda,-\lambda)$, for some $w \in \mathrm{~W}_{\lambda}$. Then clearly LAnn $V(-w \lambda,-\lambda)=I_{w_{2} \lambda}$ and so $w=1$, by 4.3. Yet this is impossible since $I_{B_{\lambda}}$ does not contain the trivial $\mathfrak{f}$ submodule. Hence (i). Now suppose $\mathbf{J} \in \mathbf{J}\left(\mathbf{I}_{\mathrm{B}_{\lambda}}\right)$ strictly contains some $I_{\alpha}^{*}$. Then since $I_{w_{\alpha} s_{\alpha} \lambda}$ is almost maximal (cf. [3], 2.19) it follows that $\sqrt{J}=I_{B_{\lambda}} . \quad$ Hence $J=I_{B_{\lambda}}$ by (i). Combined with 4.1, this gives (ii) and (iii). Suppose (iv) is false. By 3.6 (ii) and 3.1 (ii), $\mathrm{I}_{\alpha}$ admits a unique maximal submodule and by (iii) taking $\mathbf{B}^{\prime}=\{\alpha\}$, it follows that this coincides with $\mathrm{I}_{\alpha}^{*} \cap \mathrm{I}_{\alpha}$. Then $\mathrm{I}_{\alpha}^{2} \subset \mathrm{I}_{\alpha}^{*} \cap \mathrm{I}_{\alpha}$, which contradicts 4.1. Hence (iv).
4.5. The best we could do to prove that $\mathrm{I}_{\mathrm{B}^{\prime}}^{2}=\mathrm{I}_{\mathrm{B}^{\prime}}$ for all $\mathrm{B}^{\prime} \subset \mathrm{B}_{\lambda^{\prime}}$ is the following:

Proposition. - For all $\mathrm{B}^{\prime} \subset \mathrm{B}_{\lambda}$, the following statements are equivalent:
(i) $\mathrm{I}_{\mathrm{B}^{\prime}}^{2}=\mathrm{I}_{\mathrm{B}^{\prime}}$;
(ii) $\mathrm{I}_{\mathrm{B}^{\prime}}$ admits exactly card $\mathbf{B}^{\prime}$ distinct simple quotients;
(iii) $\mathrm{I}_{\mathrm{B}^{\prime}}=\sum_{\alpha \in \mathbf{B}^{\prime}} \mathrm{I}_{\alpha}$.

Recalling 3.4, we have

$$
\mathscr{V}\left(\sum_{\alpha \in \mathbf{B}^{\prime}} \mathrm{I}_{s_{\alpha} \alpha}\right)=\bigcap_{\alpha \in \mathbf{B}^{\prime}} \mathscr{V}\left(\mathrm{I}_{s_{\alpha} \alpha}\right)=\mathscr{V}\left(\mathrm{I}_{w_{\mathbf{B}^{\prime}}}\right),
$$

by [10] [4.5 (ii)]. Then $I_{w_{B^{\prime}}}=\sqrt{\sum_{x \in B^{\prime}}} I_{s_{\alpha_{\alpha}} \lambda}$, by [10] (2.1) and so (i) $\Rightarrow$ (iii).
Through 4.4 (iii), it follows that (ii) $\Rightarrow$ (i) as in the proof of 4.4 (iv). Now let K be a maximal submodule of $\mathrm{I}_{\mathbf{B}^{\prime}}$. If (iii) holds, then $\mathrm{K} \cap \mathrm{I}_{\alpha} \nsubseteq \mathrm{I}_{\alpha}$ for some $\alpha \in \mathrm{B}^{\prime}$ and so $\mathrm{I}_{\mathrm{B}^{\prime}} / \mathrm{K}=\mathrm{I}_{\alpha} /\left(\mathrm{I}_{\alpha} \cap \mathrm{K}\right)=\mathrm{I}_{\alpha} /\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\alpha}^{*}\right)$ where the last equality follows by 3.6 (iv), 3.1 (ii) and 4.4 (iii). Hence (iii) $\Rightarrow$ (ii).

Remarks. - By [7] (Prop. 12), (iii) holds if $\mathrm{B}^{\prime} \subset \mathrm{B}$ and by [10] (4.2), it is sufficient that there exists $w \in \mathrm{~W}$ such that $w \mathrm{~B}^{\prime} \subset \mathrm{B}$. Conversely by 4.4 (i) and 4.5 , we have

$$
I_{w_{\lambda} \lambda}=\sum_{\alpha \in B_{\lambda}} I_{s_{\alpha} \lambda} .
$$

This shows that for all $\lambda \in \mathfrak{h}^{*}$ regular the maximal ideal in the fibre $\pi^{-1}\left(Z_{\hat{\lambda}}\right)$ (i. e. $\left.I_{w_{2} \lambda}\right)$ though generally not itself induced ( $c f .[3], 4.2$ ) is nevertheless a sum of the induced ideals $I_{s_{\alpha} \lambda}: \alpha \in B_{\lambda}$.
4.6. Proposition. - For all $w \in \mathrm{~W}_{\lambda}, \alpha \in \tau_{\lambda}(w)$, one has $\mathrm{I}_{\alpha} \mathrm{M}(w \lambda)=\mathrm{M}\left(w s_{\alpha} \lambda\right)$. Since $\alpha \in \tau_{\lambda}(w)$, we have $w \geqq w s_{\alpha}$ by 2.2 and so by $3.2, \mathrm{M}\left(w s_{\alpha} \lambda\right)$ is a submodule of $\mathrm{M}(w \lambda)$. Then $\mathrm{I}_{\alpha} \mathrm{M}(w \lambda) \supset \mathrm{I}_{\alpha} \mathrm{M}\left(w s_{\alpha} \lambda\right)=\mathrm{M}\left(w s_{\alpha} \lambda\right)$, by 4.2.

For the opposite inclusion, let $\varepsilon$ be a real positive number and set

$$
\mathrm{C}_{\alpha, \lambda, \varepsilon}=\left\{v \in \mathfrak{h}^{*}:(v, \alpha)=0, \mathrm{~B}_{\lambda+v} \subset \mathrm{~B}_{\lambda},(v, v)<\varepsilon\right\}
$$

Assume $\varepsilon$ sufficiently small so that $\lambda+C_{\alpha, \lambda, \varepsilon}$ lies in a fixed Weyl chamber (and hence $-(\lambda+v): v \in C_{\alpha, \lambda, \varepsilon}$ is dominant). Observe that $\alpha \in B_{\lambda+v}$ and set

$$
C_{\alpha, \lambda, \varepsilon}^{0}=\left\{v \in C_{\alpha, \lambda, \varepsilon}: B_{\lambda+v}=\{\alpha\}\right\}
$$

Set $\mu:=w(\lambda+v)-w s_{\alpha}(\lambda+v)=w \lambda-w s_{\alpha} \lambda=\left(\alpha^{v}, \lambda\right) w \alpha \in \mathbf{N R}^{+} \backslash\{0\}$ and set $\beta=w \alpha$ Then $s_{\beta} w=w s_{\alpha}$, so by [8] (7.6.23), $\mathrm{M}\left(w s_{\alpha}(\lambda+v)\right)$ is a submodule of $\mathrm{M}(w(\lambda+v))$ and (cf. [8], 7.5):
( $\boldsymbol{*}$ )

$$
\operatorname{ch} \frac{\mathrm{M}(w(\lambda+v))}{\mathrm{M}\left(w s_{\alpha}(\lambda+v)\right)}=e^{w v} \operatorname{ch} \frac{\mathrm{M}(w \lambda)}{\mathrm{M}\left(w s_{\alpha} \lambda\right)} .
$$

for all $v \in \mathrm{C}_{\alpha, \lambda, \varepsilon}$. Identify (cf. [8], 7.1.5) $\mathrm{M}(w(\lambda+v))$ canonically with $\mathrm{U}\left(\mathfrak{n}^{-}\right)$. Then by [11] (Lemma 1), there exists a polynomial map $v \mapsto a_{v}$ of $\mathrm{C}_{\alpha, \lambda, \varepsilon}$ into $\mathrm{U}\left(\mathfrak{n}^{-}\right)$such that $\mathrm{M}\left(w s_{\alpha}(\lambda+v)\right)$ identifies with $\mathrm{U}\left(\mathfrak{n}^{-}\right) a_{v}$. By $(\star)$ the dimension of each weight space of $U\left(n^{-}\right) / U\left(n^{-}\right) a_{v}$ is independent of $v$. Hence the representation of $U(\mathfrak{g})$ in $\mathbf{M}(w(\lambda+v)) / \mathrm{M}\left(w s_{\alpha}(\lambda+v)\right)$ depends rationally on $v$ about $v=0$.

By [7] (Prop. 1), there exists a U module homomorphism

$$
\mathbf{B}\left(s_{\alpha},-\lambda-v,-\lambda-v\right): \quad \mathbf{L}(-\lambda-v,-\lambda-v) \rightarrow \mathbf{L}\left(-s_{\alpha}(\lambda+v),-s_{\alpha}(\lambda+v)\right)
$$

with $\operatorname{ker} B\left(s_{\alpha},-\lambda-v,-\lambda-v\right)=I_{s_{\alpha}(\lambda+v)} / I_{\lambda+v}$, [7] (Prop. 10). By [7] (Lemma 5), and 3.1 (ii), $\mathrm{I}_{s_{\alpha}(\lambda+v)} / \mathrm{I}_{\lambda+v}$ is generated by a simple $\mathfrak{f}$ submodule of type $\left(\lambda-s_{\alpha} \lambda\right)^{\wedge}$ in $\mathrm{L}(-\lambda-v,-\lambda-v)$ and hence by the lowest weight vector $f_{v}$ of this submodule. The restriction $b_{v}$ of $\mathrm{B}\left(s_{\alpha},-\lambda-v,-\lambda-v\right)$ to the lowest weight space of the isotypical component of type $\left(\lambda-s_{\alpha} \lambda\right)^{\wedge}$ in $\mathrm{L}(-\lambda-v,-\lambda-v)$ has for image the lowest weight space in the isotypical component of type $\left(\lambda-s_{\alpha} \lambda\right)^{\wedge}$ in $L\left(-s_{\alpha}(\lambda+v),-s_{\alpha}(\lambda+v)\right)$ and for suitable $n$ ( $c f .1 .5$ ) is an $n \times n$ matrix with entries depending rationally on $v$, [7] (Prop. 1). Since $-\lambda-v$ is always dominant the singularities in $b_{v}$ lie outside $\mathrm{C}_{\alpha, \lambda, \varepsilon}$. (This is made explicit in [6], III, 3.8, 4.7.) Evidently rank $b_{v}=n-1$, for all $v \in \mathrm{C}_{\alpha, \lambda, \varepsilon}$. Choose a cofactor $b_{v}^{k j}$ which is non-zero at $v=0$. Then we may write $f_{v}=\left(b_{v}^{j 1}, b_{v}^{j 2}, \ldots, b_{v}^{j n}\right)$ and so it follows that the map $v \mapsto f_{v}$ is rational in $v$ about $v=0$.

By 4.2, we have $\mathrm{I}_{s_{\alpha}(\lambda+v)} \mathrm{M}(w(\lambda+v)) \subset \overline{\mathrm{M}(w(\lambda+v))}$, and for all $v \in \mathrm{C}_{\alpha, \lambda, \varepsilon}^{0}$ one has $\overline{\mathrm{M}(w(\lambda+v))}=\mathrm{M}\left(w s_{\alpha}(\lambda+v)\right)$ by [9] (Satz 3). Let $\bar{e}_{w(\lambda+v)-\rho}$ be the representative of $e_{w(\lambda+v)-\rho}$ in $\mathrm{M}(w(\lambda+v)) / \mathrm{M}\left(w s_{\alpha}(\lambda+v)\right)$. We have shown that $f_{v} \bar{e}_{w(\lambda+v)-\rho}$ depends rationally on $v$ about $v=0$ and vanishes in the Zariski dense set $\mathrm{C}_{\alpha, \lambda, \varepsilon}^{0}$. Hence it vanishes at $v=0$ and so $\mathrm{I}_{\alpha} \mathrm{M}(w \lambda) \subset \mathrm{M}\left(w s_{\alpha} \lambda\right)$, as required.

$$
4^{\text {e }} \text { SÉRIE }- \text { TOME } 10-1977-\mathrm{N}^{\circ} 4
$$

Remarks. - The special case when $\mathfrak{g}$ is simple of type $\mathrm{A}_{2}$ and $\lambda=\rho$ was given by Dixmier [8] (7.8.12). It is not known if an arbitrary induced ideal depends rationally on the available parameters (but it does depend continuously [3], 3.9 b), and in fact the crucial point in the above argument is the description of $\mathrm{I}_{\alpha}$ through the Kunze-Stein intertwining operators. The equality $\mathrm{I}_{\alpha} \mathrm{M}(w \lambda)=\mathrm{M}\left(w s_{\alpha} \lambda\right)$ would not have followed from the second part of the proof and only follows from the deep fact noted in 4.1. (In this connection see [10], 4.6.)
4.7. We note the following fact which finds application in 7.2.

Corollary. - For each $\alpha \in \mathrm{B}_{\lambda}$, and each $w \in \mathrm{~W}_{\lambda}$ satisfying $\alpha \in \tau_{\lambda}(w)$ one has $\mathrm{I}_{s_{\alpha} \lambda}=\operatorname{Ann} \mathbf{M}(w \lambda) / \mathrm{M}\left(w s_{\alpha} \lambda\right)$.
Set $\mathrm{M}_{w}=\mathrm{M}(w \lambda) / \mathrm{M}\left(w s_{\alpha} \lambda\right)$ and $\mathrm{K}_{w}=\operatorname{Ann} \mathrm{M}_{w}$. By 4.6, one has $\mathrm{K}_{w} \supset \mathrm{I}_{s_{\alpha} \lambda}$ with equality if $w=s_{\alpha}$. Define $\operatorname{Dim}$ as in [15] (2.1). Since each $\mathrm{M}_{w}$ identifies with $\mathrm{U}\left(\mathfrak{n}^{-}\right) / \mathrm{U}\left(\mathfrak{n}^{-}\right) a_{w}$, for suitable $a_{w} \in \mathrm{U}\left(\mathfrak{n}^{-}\right)$, it follows that $\operatorname{Dim} \mathrm{M}_{w}=\operatorname{dim} \mathfrak{n}^{-}-1$. Again (cf. [2], 3.1) one has

$$
\operatorname{Dim}_{w}=\sup \left\{\operatorname{Dim} \mathrm{L}: \mathrm{L} \in \mathscr{J} \mathscr{H} \mathrm{M}_{w}\right\}
$$

and

$$
\operatorname{Dim} U(\mathfrak{g}) / K_{w}=\sup \left\{\operatorname{Dim} U(\mathfrak{g}) / \operatorname{Ann} \mathrm{L}: \mathrm{L} \in \mathscr{J} \mathscr{H} \mathrm{M}_{w}\right\} .
$$

Hence by 3.2 and [15], 2.7 it follows that $\operatorname{Dim} U(\mathfrak{g}) / \mathrm{K}_{w}=\operatorname{card} \mathrm{R}-2=\operatorname{Dim} \mathrm{U}(\mathrm{g}) / \mathrm{I}_{\mathrm{s}_{\alpha}}$. Yet $I_{s_{\alpha} \lambda}$ is a prime ideal and so by [2] (3.6), one has $K_{w}=I_{s_{\alpha} \lambda}$, as required.
4.8. For each $w \in \mathrm{~W}_{\lambda}$, consider $\mathrm{L}(-w \lambda,-\lambda)$ as a U submodule of $\mathrm{U}(\mathrm{g}) / \mathbf{I}_{\lambda}(c f .3 .7)$. Recalling 3.9, choose $w_{1} \in \mathrm{~W}_{\lambda}$ (not necessarily unique) such that L Ann $\mathrm{V}(-w \lambda,-\lambda)=\mathrm{I}_{w_{1} \lambda}$.

## Lemma:

(i) $\tau_{\lambda}\left(w_{1}\right)=\mathrm{B}_{\lambda}$, iff $w=1$;
(ii) $\mathrm{B}_{\lambda} \backslash \tau_{\lambda}\left(w_{1}\right)=\left\{\alpha \in \mathrm{B}_{\lambda}: \mathrm{I}_{\alpha} \mathrm{L}(-w \lambda,-\lambda)=\mathrm{L}(-w \lambda,-\lambda)\right\}$.
(i) follows from 4.3. (ii) follows from 3.1 (ii) which implies that $\mathrm{L}(-w \lambda,-\lambda)$ has a unique maximal submodule and the quotient is isomorphic to $\mathrm{V}(-w \lambda,-\lambda)$.
4.9. Given $w \in \mathrm{~W}_{\lambda} \backslash\{1\}$, let $w=s_{1} s_{2} \ldots s_{n}: s_{i}=s_{\alpha_{i}}: \alpha_{i} \in \mathrm{~B}_{\lambda}$, be a reduced decomposition $r$ of $w$ and set $\mathrm{J}_{w, r}:=\mathrm{I}_{\alpha_{n}} \mathrm{I}_{\alpha_{n-1}} \ldots \mathrm{I}_{\alpha_{1}}$. (We shall eventually see that $\mathrm{J}_{w, r}$ is independent of $r$.)

Proposition. - For all $w, w^{\prime} \in \mathrm{W}_{\lambda}$ with reduced decompositions $r, r^{\prime}$ one has:
(i) $\mathrm{J}_{w, r} \mathrm{M}\left(w_{\lambda} \lambda\right)=\mathrm{M}\left(w_{\lambda} w \lambda\right)$;
(ii) $\mathrm{J}_{w, r} \subset{ }^{t}(\operatorname{Ann} \mathrm{M}(w \lambda) / \mathrm{M}(\lambda)) \subset \mathrm{L}(-w \lambda,-\lambda)$;
(iii) $\mathrm{J}_{w, r} \subset \mathrm{~J}_{w^{\prime}, r}$ implies that $w \geqq w^{\prime}$.
(i) obtains on successive application of 4.6. Combined with 2.1 (ii) and 3.2, this gives (iii). Again successive application of 4.6 gives ${ }^{t} \mathrm{~J}_{w, r} \mathrm{M}(w \lambda)=\mathrm{M}(\lambda)$. Combined with 3.7 and 3.8 (ii) this gives (ii).
4.10. Recalling 2.3, let $\alpha, \beta$ be distinct elements of $B_{\lambda}$ and suppose $(\alpha, \alpha) \leqq(\beta, \beta)$. Set $k=-\left(\alpha^{\wedge}, \beta\right)$.
annales scientifiques de l’école normale supérieure

## Lemma:

(i) $\mathrm{I}_{\alpha} \mathrm{I}_{\beta}=\mathrm{I}_{\beta} \mathrm{I}_{\alpha}: k=0$;
(ii) $\mathrm{I}_{\alpha} \mathrm{I}_{\beta} \mathrm{I}_{\alpha}=\mathrm{I}_{\beta} \mathrm{I}_{\alpha} \mathrm{I}_{\beta}: k=1$;
(iii) $\left(\mathrm{I}_{\alpha} \mathrm{I}_{\beta}\right)^{k}=\left(\mathrm{I}_{\beta} \mathrm{I}_{\alpha}\right)^{k}: k=2,3$.

By 3.6 (iv), $3.7,3.8$ (iii) and 4.9 (ii) we have $\mathrm{I}_{\beta} \mathrm{I}_{\alpha} \subset \mathrm{L}\left(-s_{\alpha} s_{\beta} \lambda,-\lambda\right) \subset \mathrm{I}_{\alpha} \cap \mathrm{I}_{\beta}$. Choose $\gamma \in \mathrm{B}_{\lambda} \backslash\{\alpha, \beta\}$. If $\gamma \notin \tau_{\lambda}\left(\left(s_{\alpha} s_{\beta}\right)_{1}\right)$ (notation 4.8 ), then by 4.8 (ii), we obtain $\mathrm{I}_{\beta} \mathrm{I}_{\alpha} \subset \mathrm{L}\left(-s_{\alpha} s_{\beta} \lambda,-\lambda\right) \subset \mathrm{I}_{\lambda} \mathrm{I}_{\alpha}$, which contradicts 4.9 (iii). Then by 4.8 (i) we must either have $\alpha \notin \tau_{\lambda}\left(\left(s_{\alpha} s_{\beta}\right)_{1}\right)$ or $\beta \notin \tau_{\lambda}\left(\left(s_{\alpha} s_{\beta}\right)_{1}\right)$. Suppose the first holds. Then by 4.8 (ii), we obtain $\mathrm{I}_{\beta} \mathrm{I}_{\alpha} \subset \mathrm{I}_{\alpha} \mathrm{I}_{\beta}$. By 4.9 (iii) this can only hold if $k=0$ and then by 1.4 we obtain (i). If $k \neq 0$, then we must have $\beta \notin \tau_{\lambda}\left(\left(s_{\alpha} s_{\beta}\right)_{1}\right)$ and so from 4.8 (ii) we obtain $\mathrm{I}_{\beta} \mathrm{I}_{\alpha}=\mathrm{L}\left(-s_{\alpha} s_{\beta} \lambda,-\lambda\right)$. A similar argument with $\alpha, \beta$ interchanged gives

$$
\mathrm{I}_{\alpha} \mathrm{I}_{\beta}=\mathrm{L}\left(-s_{\beta} s_{\alpha} \lambda,-\lambda\right)
$$

Substitution from 3.7, 3.8 (iii) and 4.9 (ii) gives

$$
\mathrm{I}_{\alpha} \mathrm{I}_{\beta} \mathrm{I}_{\alpha} \subset \mathrm{L}\left(-s_{\alpha} s_{\beta} s_{\alpha} \lambda,-\lambda\right) \subset \mathrm{I}_{\alpha} \mathrm{I}_{\beta} \cap \mathrm{I}_{\beta} \mathrm{I}_{\alpha}
$$

Then by 4.8 and 4.9 (iii) either $\alpha \notin \tau_{\lambda}\left(\left(s_{\alpha} s_{\beta} s_{\alpha}\right)_{1}\right)$ or $\beta \notin \tau_{\lambda}\left(\left(s_{\alpha} s_{\beta} s_{\alpha}\right)_{1}\right)$. Suppose $\beta \notin \tau_{\lambda}\left(\left(s_{\alpha} s_{\beta} s_{\alpha}\right)_{1}\right)$. Then by 4.8 (ii), $\mathrm{I}_{\alpha} \mathrm{I}_{\beta} \mathrm{I}_{\alpha} \subset \mathrm{I}_{\beta} \mathrm{I}_{\alpha} \mathrm{I}_{\beta}$ and so $k=1$ by 4.9 (iii). Yet as above:

$$
\mathrm{I}_{\beta} \mathrm{I}_{\alpha} \mathrm{I}_{\beta} \subset \mathrm{L}\left(-s_{\beta} s_{\alpha} s_{\beta} \lambda,-\lambda\right)=\mathrm{L}\left(-s_{\alpha} s_{\beta} s_{\alpha} \lambda,-\lambda\right)=\mathrm{I}_{\alpha} \mathrm{I}_{\beta} \cap \mathrm{I}_{\beta} \mathrm{I}_{\alpha}
$$

and since $\beta \notin \tau_{\lambda}\left(\left(s_{\alpha} s_{\beta} s_{\alpha}\right)_{1}\right)$, this gives $\mathrm{I}_{\beta} \mathrm{I}_{\alpha} \mathrm{I}_{\beta}=\mathrm{L}\left(-s_{\beta} s_{\alpha} s_{\beta} \lambda,-\lambda\right)$. Recalling 1.5, it follows from 3.5 (ii) that either $\mathrm{I}_{\beta} \mathrm{I}_{\alpha} \mathrm{I}_{\beta}=\mathrm{I}_{\alpha} \mathrm{I}_{\beta} \mathrm{I}_{\alpha}$ or $\mathrm{I}_{\alpha} \mathrm{I}_{\beta} \mathrm{I}_{\alpha} \mathbf{M}\left(w_{\lambda} \lambda\right) \mp \mathbb{M}\left(w_{\lambda} s_{\alpha} s_{\beta} s_{\alpha} \lambda\right)$. The latter contradicts 4.9 (i) and so we obtain (ii). The remaining cases follow similarly.
4.11. Corollary. - For each $w \in \mathrm{~W}_{\lambda} \backslash\{1\}, \mathrm{J}_{w, r}$ is independent of the reduced decomposition $r$ of $w$.
Apply 4.10 and 2.3.
4.12. Proposition. - Choose $\mathrm{B}^{\prime} \subset \mathrm{B}_{\lambda}$ for which 4.5 (iii) holds. Then

$$
\overline{\mathbf{M}\left(w_{B^{\prime}}, \lambda\right)}=\sum_{\alpha \in \mathbf{B}^{\prime}} \mathbf{M}\left(w_{\mathbf{B}^{\prime}} s_{\alpha} \lambda\right)
$$

Set $\mathbf{M}=\sum_{\alpha \in \mathbf{B}^{\prime}} \mathbf{M}\left(w_{\mathbf{B}^{\prime}}, s_{\alpha} \lambda\right)$. Certainly $\mathbf{M} \mp \mathbf{M}\left(w_{\lambda} \lambda\right)$. Recalling [8] [7.6.1 (i) ], let $\mathbf{M}^{\prime}$ be a submodule of $\mathbf{M}\left(w_{\mathbf{B}}, \lambda\right)$ strictly containing $\mathbf{M}$ such that $\mathbf{M}^{\prime} / \mathbf{M}$ is simple and hence isomorphic to $\mathrm{L}(w \lambda)$, for some $w \leqq w_{\mathrm{B}^{\prime}}$ (by 3.2). From the hypothesis and 4.6 we obtain $\mathrm{I}_{w_{\mathbf{B}^{\prime}} \lambda} \subset \operatorname{Ann} \mathrm{M}^{\prime} / \mathbf{M}=\mathrm{I}_{w \lambda}$. By 4.1, this gives $\tau(w) \supset \tau\left(w_{\mathbf{B}^{\prime}}\right)=\mathrm{B}^{\prime}$ and so $w=w_{B^{\prime}} . \quad$ Hence $\mathbf{M}^{\prime}=\mathbf{M}\left(w_{B^{\prime}}, \lambda\right)$ and so $\mathbf{M}=\overline{\mathbf{M}\left(w_{\mathrm{B}}, \lambda\right)}$.

Remark. - In particular by 4.4 and 4.5 , it follows that $\overline{\mathrm{M}\left(w_{\lambda} \lambda\right)}=\sum_{\alpha \in \mathrm{B}_{\lambda}} \mathrm{M}\left(w_{\lambda} s_{\alpha} \lambda\right)$ and so is generated by the Verma submodules it contains. This is well-known if $\lambda \in P(R)$ ([8], 7.2.5).

## 5. Main theorems

5.0. In this section we retain the conventions of 4.0 and in addition set $\mathrm{I}_{\mathbf{B}^{\prime}}^{*}=\mathrm{I}_{w_{\lambda} w_{\mathbf{B}^{\prime}}} / \mathrm{I}_{\lambda}$, for all $\mathrm{B}^{\prime} \subset \mathrm{B}_{\lambda}$. Identify $\mathrm{L}(-w \lambda,-\lambda)$ and $\mathrm{L}(-\lambda,-w \lambda)$ with U submodules of $\mathrm{U}(\mathfrak{g}) / \mathrm{I}_{\lambda}(c f .3 .6)$.
5.1. Set $\mathrm{J}_{1}=\mathrm{U}(\mathfrak{g}) / \mathrm{I}_{\lambda}=\mathrm{L}(-\lambda,-\lambda)(c f .3 .4)$. Given $w \in \mathrm{~W}_{\lambda} \backslash\{1\}$, let

$$
w=s_{1} s_{2} \ldots s_{n}, \quad s_{i}=s_{\alpha_{i}}, \quad \alpha_{i} \in \mathrm{~B}_{\lambda}
$$

be a reduced decomposition for $w$ and recalling 4.11 set $J_{w}:=I_{s_{n}} I_{s_{n-1}} \ldots I_{s_{1}}$.
Theorem. - For all $w, w^{\prime} \in \mathrm{W}_{\lambda}$ :
(i) $\mathrm{J}_{w}=\mathrm{L}(-w \lambda,-\lambda)$;
(ii) $\mathrm{L}(-w \lambda,-\lambda)=\mathrm{L}\left(-\lambda,-w^{-1} \lambda\right)$;
(iii) $L(-\lambda,-w \lambda)=\operatorname{Ann} M(w \lambda) / M(\lambda)$;
(iv) $\mathrm{L}(-\lambda,-w \lambda) \supset \mathrm{L}\left(-\lambda,-w^{\prime} \lambda\right)$, iff $w \leqq w^{\prime}$.

The proof of (i) is by induction of $l_{\lambda}(w)$. It has already been established for $l_{\lambda}(w)=0,1$ [cf. 3.6 (ii) and 3.4]. Take $w$ as above and set $w^{\prime}=s_{1} w$. Then $l_{\lambda}\left(w^{\prime}\right)=l_{\lambda}(w)-1$, so by $3.7,3.8$ (iii), 4.9 (ii) and the induction hypothesis we obtain
( $\star$ )

$$
\mathrm{J}_{w} \subset \mathrm{~L}(-w \lambda,-\lambda) \subset \mathrm{J}_{w^{\prime}}
$$

We show that $\tau_{\lambda}\left(w_{1}\right) \supset \mathrm{B}_{\lambda} \backslash \tau_{\lambda}(w)$ (notation 4.8). If this is false choose

$$
\alpha \in \mathrm{B}_{\lambda} \backslash\left(\tau_{\lambda}(w) \cup \tau_{\lambda}\left(w_{1}\right)\right)
$$

Since $\alpha \notin \tau_{\lambda}\left(w_{1}\right)$, we obtain from 4.8 (ii) and ( $\star$ ) that $\mathrm{J}_{w} \subset \mathrm{I}_{\alpha} \mathrm{J}_{w^{\prime}}=\mathrm{J}_{w^{\prime} s_{\alpha}}$ and so by 4.9 (iii) that $w \geqq w^{\prime} s_{\alpha}$. Yet $\alpha \notin \tau_{\lambda}(w)$ and so by [10], 3.1 (iii), we obtain

$$
l_{\lambda}\left(w s_{\alpha}\right)=l_{\lambda}(w)+1=l_{\lambda}\left(w^{\prime}\right)+2
$$

Further application of [10], 3.1 (iii) and 3.1 (iv) gives $l_{\lambda}\left(w^{\prime} s_{\alpha}\right)=l_{\lambda}(w)$ and so $w=w^{\prime} s_{\alpha}$ This contradicts $\alpha \notin \tau_{\lambda}(w)$.

Through the above inclusion and 4.8 (i) it follows that there exists $\alpha \notin \tau_{\lambda}(w)$ with $\alpha \notin \tau_{\lambda}\left(w_{1}\right)$. Set $w^{\prime \prime}=w s_{\alpha}$. Then $l_{\lambda}\left(w^{\prime \prime}\right)=l_{\lambda}(w)-1$, so by $3.7,3.8$ (iii) and the induction hypothesis we obtain $\mathrm{L}(-w \lambda,-\lambda) \subset \mathrm{J}_{w^{\prime \prime}}$. Then by 4.8 (ii) and 4.11, $\mathrm{L}(-w \lambda,-\lambda) \subset \mathrm{I}_{\alpha} \mathrm{J}_{w^{\prime \prime}}=\mathrm{J}_{w}$, which combined with $(\star)$ proves the required assertion.
(ii) follows from (i), 1.4 and 3.7. (iii) follows from (i), 3.7, 3.8, 4.9 (ii). (iv) follows from (i), 3.7, 3.8 (iii) and 4.9 (iii).

Remarks. - Necessity in (iv) also follows from 3.1 (iv) and [7] (Prop. 4). By 3.1 (ii) the embedding defined in 5.1 (iv) is unique.
5.2. Theorem. - For all $w \in \mathrm{~W}_{\lambda}$, one has

$$
\operatorname{Ann} \mathrm{V}(-w \lambda,-\lambda)=\check{\mathrm{I}}_{w_{\lambda} w \lambda} \otimes \mathrm{U}(\mathrm{~g})+\mathrm{U}(\mathrm{~g}) \otimes \check{\mathrm{I}}_{w_{\lambda} w^{-1} \lambda}
$$

By 1.6 and 3.9 (ii) it is enough to show that LAnn $\mathrm{V}(-w \lambda,-\lambda)=\mathrm{I}_{w_{2} w \lambda} . \quad$ By 3.1 (ii), $\mathrm{L}(-w \lambda,-\lambda)$ admits a unique maximal submodule and so $\mathrm{I}_{w_{1} \lambda}:=\operatorname{LAnn} \mathrm{V}(-w \lambda,-\lambda)$
is just the largest element of $\mathbf{J}\left(\mathrm{U}(\mathfrak{g}) / I_{\lambda}\right)$ such that $\mathrm{I}_{w_{1} \lambda} \mathrm{~L}(-w \lambda,-\lambda) \mp \mathrm{L}(-w \lambda,-\lambda)$. By 5.1, 4.9 (i) and 3.5 (i) this is equivalent to $\mathrm{I}_{w_{1} \lambda} \mathrm{M}\left(w w_{\lambda} \lambda\right) \subset \overline{\mathrm{M}\left(w w_{\lambda} \lambda\right)}$, which gives the required assertion.
5.3. In [7] (II), Duflo notes that for each $\mathrm{I} \in \operatorname{Spec}\left(\mathrm{U}(\mathrm{g}) / \mathrm{I}_{\mathrm{N}}\right)$, there exists a unique smallest $\mathbf{J} \in \mathbf{J}\left(\mathbf{U}(\mathrm{g}) / \mathrm{I}_{\lambda}\right)$ strictly containing I . When $\mathrm{I}=\mathrm{I}_{\mathbf{B}^{*}}^{*}$ we compute $\mathbf{J}$ below.
Theorem. - For all $\mathrm{B}^{\prime} \subset \mathrm{B}_{\lambda}$ :
(i) $\mathbf{J}_{w_{\mathrm{B}^{\prime}}}$, is the smallest element of $\mathbf{J}\left(\mathrm{U}(\mathrm{g}) / \mathrm{I}_{\lambda}\right)$ with radical equal to $\bigcap_{\alpha \in \mathrm{B}^{\prime}} \mathrm{I}_{\alpha}$. In particular $\mathrm{J}_{w_{\mathrm{B}^{\prime}}}=\left(\bigcap_{\alpha \in \mathrm{B}^{\prime}} \mathrm{I}_{\alpha}\right)^{l}$, for all integer $l$ sufficiently large;
(ii) $\mathrm{J}_{\mathbf{w}_{\mathrm{B}^{\prime}}}+\mathrm{I}_{\mathbf{B}^{\prime}}^{*}$, is the unique smallest element of $\mathbf{J}\left(\mathrm{U}(\mathrm{g}) / \mathrm{I}_{\mathrm{A}}\right)$ strictly containing $\mathrm{I}_{\mathbf{B}^{\prime}}^{*}$ Furthermore $\left(\mathrm{J}_{w_{\mathbf{B}^{\prime}}}+\mathrm{I}_{\mathrm{B}^{\prime}}^{*}\right) / I_{\mathbf{B}^{\prime}}^{*}=\mathrm{V}\left(-w_{\mathbf{B}^{\prime}} \lambda,-\lambda\right)$, up to $a \mathrm{U}$ module isomorphism.
Choose $\mathbf{J} \in \mathbf{J}\left(\mathrm{U}(\mathfrak{g}) / \mathrm{I}_{\lambda}\right)$ such that $\sqrt{\mathbf{J}}=\bigcap_{\alpha \in \mathbf{B}^{\prime}} \mathrm{I}_{\alpha}$, and set $\mathrm{K}=\mathbf{J}+\mathrm{I}_{\lambda}$, considered as an element of $\mathbf{J}\left(\mathrm{U}(\mathrm{g})\right.$ ). By [10] [2.1 (v) (notation 3.4)] we have $\mathscr{V}(\mathrm{K})=\bigcup_{\alpha \in \mathrm{B}^{\prime}} \mathscr{V}\left(\mathrm{I}_{s_{\alpha}}\right)$,, Then by [10] [2.1 (i), 2.1 (ii)], the inclusion $K \subset I_{w_{\lambda} w_{B^{\prime}} \lambda}$ implies $w_{\lambda} w_{B}, \lambda \in \mathscr{V}\left(\mathrm{I}_{s_{\mathrm{A}} \lambda}\right)$, for some $\beta \in B^{\prime}$ and so by [10], 2.1 (i) that $I_{w_{\lambda} w_{B^{\prime} \lambda}} \supset I_{s_{\beta} \lambda}$. This contradicts 4.1. Hence $\left(\mathrm{J}+\mathrm{I}_{\mathrm{B}^{\prime}}^{*}\right) / I_{\mathrm{B}^{\prime}}^{*} \neq 0$. In particular we may take $\mathrm{J}=\mathrm{J}_{w_{\mathrm{B}^{\prime}}}$, and then by 5.1 (i) and 3.5 (ii) this gives (ii). Again if $\mathrm{J} \nsubseteq \mathrm{J}_{w_{\mathrm{B}^{\prime}}}$, then by 3.5 (i), $\mathrm{KM}\left(w_{\lambda} w_{\mathrm{B}^{\prime}}, \lambda\right) \subset \overline{\mathrm{M}\left(w_{\lambda} w_{\mathrm{B}^{\prime}}, \lambda\right)}$ which implies $K \subset I_{w_{\lambda} w_{B^{\prime}}}$. This contradiction gives (i).
5.4. Fix $w, w^{\prime} \in \mathrm{W}_{\lambda}$ satisfying $l_{\lambda}\left(w^{\prime} w\right)=l_{\lambda}\left(w^{\prime}\right)+l_{\lambda}(w)$. Then $\mathrm{M}\left(w^{\prime} \lambda\right)$ is a submodule of $\mathrm{M}\left(w^{\prime} w \lambda\right)$ and we set $\mathrm{J}_{w}^{w^{\prime}}=\operatorname{Ann} \mathbf{M}\left(w^{\prime} w \lambda\right) / \mathrm{M}\left(w^{\prime} \lambda\right), \overline{\mathrm{J}_{w}^{w^{\prime}}}=\mathrm{Ann} \mathrm{M}\left(w^{\prime} w \lambda\right) / \overline{\mathrm{M}\left(w^{\prime} \lambda\right)}$ computed in $\mathrm{U}(\mathrm{g}) / \mathrm{I}_{\lambda}$. Certainly $\overline{\mathbf{J}_{w} w^{\prime}} \subset \mathrm{J}_{w}^{w^{\prime}}$. Let $\mathrm{B}\left(w^{\prime},-\lambda,-w \lambda\right)$ be the U module homomorphism of $\mathrm{L}(-\lambda,-w \lambda)$ into $\mathrm{L}\left(-w^{\prime} \lambda,-w^{\prime} w \lambda\right)$ defined in [7] (Prop. 1), and let $\psi_{w^{\prime} w \lambda, w^{\prime} \lambda}($ or simply, $\psi)$ be the $U$ module homomorphism of $L\left(M\left(w^{\prime} w \lambda\right), M\left(w^{\prime} \lambda\right)\right)$ into $\mathrm{L}\left(-w^{\prime} \lambda,-w^{\prime} w \lambda\right)$ defined in 3.4.

Theorem:
(i) $\mathrm{L}(-\lambda,-w \lambda) \subset \mathrm{J}_{w}^{w^{\prime}}$, with equality if $w^{\prime}=1$ or $w=s_{\alpha}: \alpha \in \mathrm{B}_{\lambda}$;
(ii) $\left.\mathrm{UL}^{0}\left(-w^{\prime} \lambda,-w^{\prime} w \lambda\right)=\psi(\mathrm{L}(-\lambda,-w \lambda)) \subset \overline{\left(\mathrm{M}\left(w^{\prime} \lambda\right)\right.} \otimes \mathrm{M}\left(w^{\prime} w \lambda\right)\right)^{\perp}$;
(iii) up to a non-zero scalar (depending on $w^{\prime} w \lambda$ and $w^{\prime} \lambda$ ) the restriction of $\Psi_{w^{\prime} w \lambda, w^{\prime} \lambda}$ to $\mathrm{L}(-\lambda,-w \lambda)$ coincides with $\mathrm{B}\left(w^{\prime},-\lambda,-w \lambda\right)$;
(iv) $\operatorname{ker} \mathrm{B}\left(w^{\prime},-\lambda,-w \lambda\right)=\overline{\mathrm{J}_{w} w^{\prime}} \cap \mathrm{L}(-\lambda,-w \lambda)$.
(i) obtains from 4.6, 4.7 and 5.1. Then by 3.4 (i), 4.9, 5.1,

$$
\psi\left(\mathrm{L}^{0}(-\lambda,-w \lambda)\right)=\mathrm{L}^{0}\left(-w^{\prime} \lambda,-w^{\prime} w \lambda\right),
$$

which by 3.1 (ii) gives the first part of (ii). By [11] (Sect. 2), the bilinear form $\langle$, defined on $\mathrm{M}\left(w^{\prime} \lambda\right)$ has kernel $\overline{\mathrm{M}\left(w^{\prime} \lambda\right)}$. Hence $\left.\operatorname{Im} \psi \subset \overline{\left(\mathrm{M}\left(w^{\prime} \lambda\right)\right.} \otimes \mathrm{M}\left(w^{\prime} w \lambda\right)\right)^{\perp}$ which gives the second part of (ii). By 3.1 (ii), any $U$ module homomorphism of $\mathrm{L}(-\lambda,-w \lambda)$ into $\mathrm{L}\left(-w^{\prime} \lambda,-w^{\prime} w \lambda\right)$ is determined by its restriction to the lowest weight vector of the f -submodule $\mathrm{L}^{0}(-\lambda,-w \lambda)$. Hence (iii) and (iv).

$$
4^{\text {e }} \text { SÉRIE }- \text { tome } 10-1977-\text { No}^{\circ} 4
$$

Remarks. - The importance of (iii) is that it gives a new way of representing the KunzeStein intertwining operators $\mathrm{B}\left(w^{\prime},-\lambda,-w \lambda\right)$. Taking $w^{\prime} w=w_{\lambda}$ and recalling the argument of 3.9 , we see that (ii) implies 5.2 and is indeed a stronger result. Taking $w=1$ in (iv), we recover [7] (Prop. 10) as a special case. It would be rather useful to establish equality in (i). For example this would give ker B $\left(w^{\prime},-\lambda,-w \lambda\right)=\overline{\mathbf{J}_{w}}{ }_{w}^{w^{\prime}}$ and a further application is noted in 7.1. It is part of a general question raised in [8] (Prob. 30). By 4.7 and the definition of $\mathrm{J}_{w}$, it follows that $\mathrm{L}(-\lambda,-w \lambda)$ and $\mathrm{J}_{w}^{w^{\prime}}$ have the same radical. Again we note that

$$
\overline{\mathrm{J}}_{w}^{s_{\alpha}}=\operatorname{Ann~M}\left(s_{\alpha} w \lambda\right) / \mathrm{M}(\lambda)=\mathrm{L}\left(-\lambda,-s_{\alpha} w \lambda\right) \subset \mathrm{L}(-\lambda,-w \lambda),
$$

by 5.1 and so $\operatorname{ker} \mathrm{B}\left(s_{\alpha},-\lambda,-w \lambda\right)=\mathrm{L}\left(-\lambda,-s_{\alpha} w \lambda\right)$, which is essentially [7] (Lemma 5). Finally does one have $\operatorname{ker} \mathrm{B}\left(w^{\prime},-\lambda,-w \lambda\right)=\left(\mathrm{I}_{w^{\prime} \lambda} / \mathrm{I}_{\lambda}\right) \mathrm{L}(-\lambda,-w \lambda)$ ? By (iv) they have the same radical.
5.5 Take $w \in \mathrm{~W}_{\lambda}$. Then $\sum_{w^{\prime}<w} \mathrm{M}\left(w^{\prime} \lambda\right)$ is generally a strict submodule of $\overline{\mathrm{M}(w \lambda)}$. Recalling 3.1 (ii) let $\overline{\mathrm{L}(-\lambda,-w \lambda)}$ denote the unique maximal submodule of $\mathrm{L}(-\lambda,-w \lambda)$. By 1.5 and 5.1 (iv), $\sum_{w^{\prime}<w} \mathrm{~L}\left(-\lambda,-w^{\prime} \lambda\right)$ is contained in $\overline{\mathrm{L}(-\lambda,-w \lambda)}$ and we show that this inclusion is generally strict.
Lemma. - Take $\alpha \in \mathrm{B}_{\lambda}$ and set $\mathrm{B}^{\prime}=\mathrm{B}_{\lambda} \backslash\{\alpha\}$. If $\mathrm{I}_{\alpha}^{*} \nsupseteq \mathrm{I}_{\mathrm{B}^{\prime}}$, then $\mathrm{J}:=\sum_{w^{\prime}>s_{\alpha}} \mathrm{L}\left(-\lambda,-s_{\alpha} \lambda\right)$ is a strict submodule of $\overline{\mathrm{L}\left(-\lambda,-s_{\alpha} \lambda\right)}$.
By 4.1 and 5.1, $\mathrm{J}=\sum_{\beta \in \mathrm{B}^{\prime}}\left(\mathrm{I}_{\alpha} \mathrm{I}_{\beta}+\mathrm{I}_{\beta} \mathrm{I}_{\alpha}\right) \subset \mathrm{I}_{\alpha} \cap \mathrm{I}_{\mathrm{B}^{\prime}} . \quad$ By 4.4 and 4.5,

$$
\mathrm{I}_{\alpha} /\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\mathrm{B}^{\prime}}\right) \cong\left(\mathrm{I}_{\alpha}+\mathrm{I}_{\mathrm{B}^{\prime}}\right) / \mathrm{I}_{\mathrm{B}^{\prime}}=\mathrm{I}_{\mathrm{B}^{\prime} /} / \mathrm{I}_{\mathrm{B}^{\prime}}
$$

which by 4.4 (iii) is a simple $U$ module iff $\mathrm{I}_{\mathrm{B}^{\prime}}=\mathrm{I}_{\alpha}^{*}$. This establishes the required assertion.
Example. - Take R of type $\mathrm{A}_{3}$ with $\lambda \in \mathrm{P}(\mathrm{R})$ and $\alpha=\alpha_{2}$. By [3] (4.4, 4.17), one has $\mathrm{I}^{*} \mp \mathrm{I}_{\mathrm{B}^{\prime}}$. Also $\overline{\mathrm{M}\left(w_{\lambda} s_{\alpha} \lambda\right)}$ is not generated by the Verma modules it contains.
5.6. Fix $-\lambda \in \mathfrak{b}^{*}$ dominant and let $\mathrm{L}(\mathrm{L}(w \lambda), \mathrm{L}(w \lambda)): w \in \mathrm{~W}_{\lambda}$ denote the subspace of all $\mathfrak{f}$ finite elements of $\operatorname{Hom}(\mathrm{L}(w \lambda), \mathrm{L}(w \lambda)$ ) (which is a U submodule). Recalling 3.4, let $\langle$,$\rangle denote the non-degenerate bilinear \mathfrak{i}$ invariant form on $\mathrm{L}(w \lambda)$. Given $\mathrm{T} \in \mathrm{L}(\mathrm{L}(w \lambda), \mathrm{L}(w \lambda))$ define $\psi_{\mathrm{T}} \in(\mathrm{L}(w \lambda) \otimes \mathrm{L}(w \lambda))^{*}$ through $\left(\psi_{\mathrm{T}}, m \otimes n\right)=\langle m, \mathrm{~T} n\rangle$, for all $m, n \in \mathrm{~L}(w \lambda)$. Let $\overline{(\mathrm{M}(w \lambda) \otimes \mathrm{M}(w \lambda))}$ denote the unique maximal submodule of $\mathrm{M}(w \lambda) \otimes \mathrm{M}(w \lambda)$ and let $\overline{(\mathrm{M}(w \lambda) \otimes \mathrm{M}(w \lambda))^{\perp} \text { denote its orthogonal complement }}$ in $(M(w \lambda) \otimes M(w \lambda))^{*}$.

Lemma. - The map $\psi: \mathrm{T} \mapsto \psi_{\mathrm{T}}$ induces $a \mathrm{U}$ module isomorphism of $\mathrm{L}(\mathrm{L}(w \lambda), \mathrm{L}(w \lambda))$ onto $\mathrm{L}(-w \lambda,-w \lambda) \cap \overline{(\mathrm{M}(w \lambda) \otimes \mathrm{M}(w \lambda))^{\perp}}$.

It follows exactly as in [5], 5.5 that $\psi$ is a $U$ module isomorphism of $\mathrm{L}(\mathrm{L}(w \lambda), \mathrm{L}(w \lambda))$ onto the subspace of all $\mathfrak{f}$ finite elements of $(\mathrm{L}(w \lambda) \otimes \mathrm{L}(w \lambda))^{*}$ which further identifies with the subspace of all $f$ finite elements of $(\mathrm{M}(w \lambda) \otimes \mathrm{M}(w \lambda))^{\perp}$. This gives the required assertion.
5.7. From say 3.3 we obtain an embedding $\mathrm{U}(\mathfrak{g}) / \mathrm{I}_{w \lambda} \subseteq \mathrm{~L}(\mathrm{~L}(w \lambda), \mathrm{L}(w \lambda))$. This is generally strict (cf. [5], 6.5). Yet

Theorem. - For all - $\lambda \in \mathfrak{b}$ * dominant and regular one has

$$
\mathrm{U}(\mathrm{~g}) / \mathrm{I}_{w_{\lambda} \lambda}=\mathrm{L}\left(\mathrm{~L}\left(w_{\lambda} \lambda\right), \mathrm{L}\left(w_{\lambda} \lambda\right)\right) .
$$

Set $\mathrm{L}=\mathrm{L}\left(\mathrm{L}\left(w_{\lambda} \lambda\right), \mathrm{L}\left(w_{\lambda} \lambda\right)\right) . \quad$ By 3.1 (iv) and $5.6, \mathrm{~L}$ has finite length as a U module. Let V be one of its non-zero simple U subquotients. Since $\check{\mathrm{I}}_{w_{w_{\lambda} \lambda}} \mathrm{L}=0$, we obtain from 1.4 and 1.6 that LAnn $\mathrm{V} \supset \mathrm{I}_{w_{\lambda} \lambda}$. This by 4.3 and the maximality of $\mathrm{I}_{w_{2} \lambda}$ gives $\mathrm{V}=\mathrm{V}(-\lambda,-\lambda)$ up to isomorphism. By 3.1 (iv) and $5.6, \mathrm{~V}(-\lambda,-\lambda)$ occurs with multiplicity at most once in $L$ which is therefore itself a simple $U$ module. Hence $\mathrm{L}=\mathrm{U}(\mathrm{g}) / \mathrm{I}_{w_{\lambda} \lambda}$ as required.

Remark. - In the special case for which $\mathrm{B}_{\lambda} \subset \mathrm{B}$ this result is due to Conze-Berline and Duflo (combine 2.12, 6.2, 6.3 of [5]). More generally they show that

$$
\mathrm{L}\left(\mathrm{~L}\left(w_{\mathrm{B}}, \lambda\right), \mathrm{L}\left(w_{\mathrm{B}^{\prime}}, \lambda\right)\right)=\mathrm{U}(\mathfrak{g}) / \mathrm{I}_{w_{\mathrm{B}}, \lambda},
$$

for all $B^{\prime} \subset\left(B_{\lambda} \cap B\right)$ and $-\lambda$ dominant. For $\lambda$ regular we sketch an alternative proof based on 5.7. Let $\varepsilon$ be a real positive number and set $C_{B^{\prime}, \lambda, \varepsilon}=\left\{v \in \mathfrak{b}^{*}:(v, \alpha)=0: \alpha \in B^{\prime}\right.$, $\left.B_{\lambda+v} \subset B_{\lambda},(v, v)<\varepsilon\right\}$. Given $B^{\prime} \subset B$ and taking $\varepsilon$ sufficiently small it follows from [6], 3.9 and 4.3.3 (as pointed out to me by Duflo) that $B\left(w_{B^{\prime}},-(\lambda+v),-(\lambda+v)\right.$ ) is independent of $v \in C_{B^{\prime}, \lambda, \varepsilon}$. Hence by [7], Prop. 10, $I_{w_{B^{\prime}}(\lambda+v)} / I_{\lambda+v}$ is independent of $v$. By [10], 4.3, this also holds when $\mathrm{B}^{\prime}=\{\alpha\} \subset B$ and hence it is true for any subset $\mathrm{B}^{\prime}$ of B satisfying 4.5 (iii). Conversely since we can always choose $v \in C_{B^{\prime}, \lambda, \varepsilon}$ such that $\mathrm{B}^{\prime}=\mathrm{B}_{\lambda+v}$, the independence of $\mathrm{I}_{\mathbf{w}_{\mathbf{B}^{\prime}}(\lambda+v)} / \mathrm{I}_{\lambda+v}$ on $v$ implies 4.5 (iii). This gives an independent proof of [7], Proposition 12. By 4.5 (iii) and 4.12 it follows that $\mathrm{L}\left(w_{\mathrm{B}^{\prime}}(\lambda+\mathrm{v})\right)$ identifies with an induced module. Then by $5.6, \mathrm{~L}\left(\mathrm{~L}\left(w_{\mathrm{B}^{\prime}}(\lambda+v), w_{\mathrm{B}^{\prime}}(\lambda+v)\right)\right.$ identifies with a principle series module and so as a $\mathfrak{f}$ module is independent of $v$. Taking $v$ so that $\mathbf{B}^{\prime}=\mathbf{B}_{\lambda+v}$ the required assertion follows from 5.7.

## 6. The symmetric group

6.0. Theorem 5.2 is slightly unsatisfactory in the sense that the $\mathrm{I}_{w \lambda}: w \in \mathrm{~W}_{\lambda}$ are not pairwise distinct. Here we recast this formula into a better form when $W_{\lambda}$ is of type $A_{n-1}$ (that is when it is isomorphic to the symmetric group $S_{n}$ ). We follow the notation of [10] (Sect. 7), briefly outlined below.
6.1. Let $n$ be an integer $>0, \xi$ a partition of $n$ and set $|\xi|=n$. Let $\mathrm{S} t(\xi)$ [resp. $\mathrm{Yg}(\xi)]$ denote the set of standard (resp. Young) Tableaux of type $\xi$. Given $\mathrm{T} \in \mathrm{Yg}(\xi)$, let $\mathrm{T}^{i}$ (resp. $\mathrm{T}_{i}$ ):i=1,2,,$n$, denote the columns (resp. rows) of T and $m(\mathrm{~T})$ the set of positive integers (assumed pairwise distinct) occurring in T. We recall that by definition $m(\mathrm{~T})=\{1,2, \ldots, n\}$ iff $\mathrm{T} \in \mathrm{St}(\xi)$.
6.2. By an ordinal we mean an element of $\mathbf{N}^{+} \cup\{\infty\}$ given its natural order. Let $\mathbf{T}$ be a Young Tableau and $k, l$ positive integers not occurring in $m(\mathrm{~T})$. We define a new Table $T \vee k$ (resp. $T \cup l$ ) by the following rule. First complete $T$ to an infinite square

```
4e série - tome 10 - 1977 - No 4
```

array by putting $\infty$ into the empty places. Then define ordinals $k_{0} \leqq k_{1} \leqq k_{2} \leqq \ldots$ (resp. $l_{0} \leqq l_{1} \leqq l_{2} \leqq \ldots$ ) inductively as follows. Set $k_{0}=k$ (resp. $l_{0}=l$ ) and for each $i \in \mathbf{N}^{+}$, let $k_{i}\left(\right.$ resp. $\left.l_{i}\right)$ be the smallest ordinal $\geqq k_{i-1}$ (resp. $l_{i-1}$ ) in $\mathbf{T}^{i}$ (resp. $\mathrm{T}_{i}$ ). Finally set $(\mathrm{T} \vee k)^{i}=\left(\mathrm{T}^{i} \backslash\left\{k_{i}\right\}\right) \cup\left\{k_{i-1}\right\} \quad$ [resp. $\left.(\mathrm{T} \cup l)_{i}=\left(\mathrm{T}_{i} \backslash\left\{l_{i}\right\}\right) \cup\left\{l_{i-1}\right\}\right]$. The following result is due to Schensted [16] (Lemma 6).

Lemma. - Let T be a Young Tableau (possibly the trivial empty Tableau). Given $k, l \in \mathbf{N}^{+} \backslash m(\mathrm{~T})$ distinct, then $(\mathrm{T} \vee k) \cup l=(\mathrm{T} \cup l) \vee k$.

Define $k_{1}, k_{2}, \ldots$ (resp. $l_{1}, l_{2}, \ldots$ ) as above and call it the $k$ (resp. $l$ )-sequence. Observe, for example, that $l_{i-1}$ takes the place of $l_{i}$ in ( $\mathrm{T} \cup l$ ) and that the $l$-sequence moves downwards and to the left in T. Both sequences are increasing and hence have either exactly one common element which is finite, or (possibly) several infinite ones. Choose $r, s \in \mathbf{N}^{+}$such that $l_{r}=k_{s}$. We can assume without loss of generality that there are no further common elements and that $l_{r-1}, k_{s-1}<\infty$. One has $l_{r} \in \mathrm{~T}^{s}$ and so either $r=1$ or $l_{r-1} \in \mathrm{~T}^{v}$, for some $v \geqq s$. Again $s=1$ or $k_{s-1} \in \mathrm{~T}_{u}$, for some $u \geqq r$. Suppose $u=r$. Then $l_{r-1}>k_{s-1}$ by definition of the $l$-sequence and so $v>s$ (for otherwise $k_{s-1}>l_{r-1}$ by definition of the $k$-sequence). Now

$$
(\mathrm{T} \cup l)_{s}=\left(\mathrm{T}_{s} \backslash\left\{l_{s}\right\}\right) \cup\left\{l_{s-1}\right\} \quad \text { and } \quad(\mathrm{T} \vee k)_{s}=\left(\mathrm{T}_{s} \backslash\left\{k_{t}\right\}\right) \cup\left\{k_{t-1}\right\},
$$

for some ordinal $t \geqq v>s$. Hence $((\mathrm{T} \vee k) \cup l)_{s}=\left(\mathrm{T}_{s} \backslash\left\{l_{s}, k_{t}\right\}\right) \cup\left\{k_{t-1}, l_{s-1}\right\}$. Again since $l_{r}=k_{s}$, it follows from the definition of the $k$-sequence that $l_{r-1}$ is the smallest integer $>k_{s-1}$ in $(\mathrm{T} \cup l)^{s}$. Hence $((\mathrm{T} \cup l) \vee k)_{s}=\left(\mathrm{T}_{s} \backslash\left\{l_{s}, k_{t}\right\}\right) \cup\left\{k_{t-1}, l_{s-1}\right\}$, as required. The remaining rows coincide because they do not contain the intersection point of the sequences. The case $u>r, v>s, l_{r-1}>k_{s-1}$ is exactly the same and the remaining cases follow by interchanging rows and columns.
Remark. - The above proof is different and shorter than Schensted's which uses induction on $n$.
6.3. Given $\mathrm{T} \in \mathrm{Yg}(\xi)$, then after Robinson (cf. [10], 7.5 (i)), we can always write $\mathrm{T}=\left(\left(\ldots\left(l_{1} \cup l_{2}\right) \cup l_{3}\right) \cup \ldots \cup l_{n}\right.$, for some (pairwise distinct) $l_{i} \in \mathbf{N}^{+}$. Given $l \in \mathbf{N}^{+} \backslash m(\mathrm{~T})$, set $l \cup \mathrm{~T}:=\left(\left(\ldots\left(l \cup l_{1}\right) \cup l_{2}\right) \cup \ldots \cup l_{n}\right.$. Let $\mathrm{T}^{*}$ denote the Young Table obtained by rotating T about its main diagonal.

Corollary (Schensted [16], Lemma 7):
(i) $l \cup \mathrm{~T}=\mathrm{T} \vee l$;
(ii) $\left(\left(\ldots\left(l_{1} \cup l_{2}\right) \cup l_{3}\right) \cup \ldots \cup l_{n}\right)^{*}=\left(\left(\ldots\left(l_{n} \cup l_{n-1}\right) \cup l_{n-2}\right) \cup \ldots \cup l_{1}\right.$;
(i) follows easily from 6.2. For (ii), observe that $(\mathrm{T} \cup l)=\left(\mathrm{T}^{*} \vee l\right)^{*}=\left(l \cup \mathrm{~T}^{*}\right)^{*}$, by (i). Hence $\left(l \cup \mathrm{~T}^{*}\right)=(\mathrm{T} \cup l)^{*}$ and (ii) follows by induction on $n$.
6.4. Assume that $R$ is of type $A_{n-1}$. Then $W_{\lambda}$ is isomorphic to the symmetric group $\mathrm{S}_{n}$ which we consider as the permutation group of $\{1,2, \ldots, n\}$. For each $w \in \mathrm{~S}_{n}$, set $k_{i}=w^{-1} i: i=1,2, \ldots, n$ and $\mathrm{A}(w):=\left(\left(\ldots\left(k_{1} \cup k_{2}\right) \cup k_{3}\right) \cup \ldots \cup k_{n}\right.$, $\mathrm{B}(w):=\mathrm{A}\left(w^{-1}\right)$. Then after Robinson, Schensted and Schützenberger (cf. [10], 7.5), the map $\Phi: w \mapsto(\mathrm{~A}(w), \mathrm{B}(w))$ is a bijection of $\mathrm{S}_{n}$ onto $: \bigcup\{\mathrm{Yg}(\xi) \times \mathrm{Yg}(\xi):|\xi|=n\}$.

## Lemma:

(i) $\mathrm{A}\left(w_{\lambda} w\right)=\mathrm{A}(w)^{*}$;
(ii) $\mathrm{A}\left(w_{\lambda} w^{-1}\right)=\mathrm{B}(w)^{*}$.

One has $\left(w_{\lambda} w\right)^{-1} i=w^{-1}(n+1-i)=k_{n+1-i}$ and so (i) follows from 6.3 (ii). By (i), $\mathrm{B}(w)^{*}=\mathrm{A}\left(w^{-1}\right)^{*}=\mathrm{A}\left(w_{\lambda} w^{-1}\right)$, which is (ii).
6.5. Hypotheses 6.4. - For each $w \in \mathrm{~W}_{\lambda}$ define the involutions

$$
\left.\sigma_{1}(w):=\Phi^{-1}\left(\mathrm{~A}(w)^{*}\right), \mathrm{A}(w)^{*}\right) \quad \sigma_{2}(w):=\Phi^{-1}\left(\mathrm{~B}(w)^{*}, \mathrm{~B}(w)^{*}\right) .
$$

Through the injectivity of $\Phi$, the map $w \mapsto\left(\sigma_{1}(w), \sigma_{2}(w)\right)$ of $\mathrm{W}_{\lambda}$ into $\left(\Sigma_{\lambda}, \Sigma_{\lambda}\right)$ is injective.
Theorem ( $\mathrm{R}_{\lambda}$ of type $\mathrm{A}_{n-1}$ ). - For all $w \in \mathrm{~W}_{\lambda}$, one has

$$
\operatorname{Ann} \mathrm{V}(-w \lambda,-\lambda)=\check{\mathrm{I}}_{\sigma_{1}(w) \lambda} \otimes \mathrm{U}(\mathrm{~g})+\mathrm{U}(\mathrm{~g}) \otimes \check{\mathrm{I}}_{\sigma_{2}(w) \lambda} .
$$

This follows 5.2, 6.4, and [10] (5.1, 6.1 and 7.9).
6.6. Corollary ( $\mathrm{R}_{\lambda}$ of type $\mathrm{A}_{n-1}$ ). - The following two statements are equivalent:
(i) $\operatorname{card} \mathbf{X}_{\hat{\lambda}}=\operatorname{card} \Sigma_{\lambda}$;
(ii) card $\left\{\operatorname{Ann} \mathrm{V}(-w \lambda,-\lambda): w \in \mathrm{~W}_{\lambda}\right\}=\operatorname{card} \mathrm{W}_{\lambda}$.

Remark. - If $\lambda \in \mathrm{P}(\mathrm{R})$, then after Borho-Jantzen ([3], [4]), (i) holds up to $n=6$.
6.7. If $B_{\lambda}$ admits roots $\alpha, \beta$ which span a subsystem of type $B_{2}$ or $G_{2}$ one has $I_{s_{\alpha} \lambda}=I_{s_{\alpha} s_{\beta} s_{\alpha} \lambda}$ by [10] (5.1). Then by 5.2

$$
\operatorname{Ann} \mathrm{V}\left(-w_{\lambda} s_{\alpha} \lambda,-\lambda\right)=\operatorname{Ann} \mathrm{V}\left(-w_{\lambda} s_{\alpha} s_{\beta} s_{\alpha} \lambda,-\lambda\right)
$$

and since $w_{\lambda}=-1$ (under the above hypothesis) this gives card $\mathbf{X}_{\hat{\lambda}}<\operatorname{card} \Sigma_{\lambda}$ by 3.9 (iii). Consequently card $\left\{\mathrm{V}(-w \lambda,-\lambda): w \in \mathrm{~W}_{\lambda}\right\}<$ card $\mathrm{W}_{\lambda}$ and one can expect this to also hold if $R_{\lambda}$ admits a subsystem of type $D_{n}$ or $E_{n}$. Yet it is plausible that

$$
\operatorname{Ann} \mathrm{V}(-w \lambda,-\lambda) \neq \operatorname{Ann} \mathrm{V}\left(-w^{-1} \lambda,-\lambda\right) \quad \text { if } \quad w \neq w^{-1}
$$

holds in general. In case $\mathrm{A}_{n-1}$ such a result would distinguish the $\left\{\mathrm{I}_{\sigma \lambda}: \sigma \in \Sigma_{\lambda}\right\}$ associated through $\Phi$ with standard Tableaux of the same form (i. e. defined by the same partition $\xi$ ). Furthermore if $\sigma=\Phi^{-1}(\mathrm{~A}, \mathrm{~A})$ with $\mathrm{A} \in \mathrm{S} t(\xi)$, then one expects that the zero variety of the graded ideal $\mathrm{gr}_{\mathrm{\sigma} \lambda}$ will admit a dense nilpotent orbit corresponding to $\xi$ (cf. [1], 5.9) and together these results would distinguish the $\left\{\mathrm{I}_{\sigma \lambda}: \sigma \in \Sigma_{\lambda}\right\}$. In [15] (4.2), when $\mathfrak{g}$ itself is of type $\mathrm{A}_{n-1}$ we have already shown that the zero variety of $\mathrm{gr} \mathrm{I}_{\mathrm{\sigma} \lambda}$ has the expected dimension. This is an important and rather non-trivial application of our main result 5.2. It further allows us to classify $\mathbf{X}_{\hat{\lambda}}$ when card $B_{\lambda}=3$, [15] (Sect. 5). Finally we remark that Spaltenstein [12] has pointed out in case $\mathrm{A}_{n-1}$ that the Robinson map $\Phi$ can be viewed as the inverse of a map recently introduced by Steinberg in connection with the unipotent variety. The Steinberg map is defined without restriction on type; but in the general case there is a tantalizing distinction between this map and what would be required to generalize 6.5 for arbitrary $W_{\lambda}$.

## 7. The rank 2 case

7.1. Retain the notation and conventions of 4.0. It is well-known and follows easily from 5.3 (i) that card $J\left(U(g) / I_{\lambda}\right)=1+\operatorname{card} B_{\lambda}$, if card $B_{\lambda} \leqq 1$. Here we consider the case when card $B_{\lambda}=2$. In this situation Jantzen [14], has recently shown that $\mathscr{J} \mathscr{H} \mathrm{M}\left(w_{\lambda} \lambda\right)$ is multiplicity free. It is natural to then ask if $\mathscr{J} \mathscr{H} \mathrm{L}(-\lambda,-\lambda)$ is also multiplicity free and we remark that such a result leads easily to a complete description of $\mathbf{J}\left(\mathrm{U}(\mathfrak{g}) / \mathrm{I}_{\lambda}\right)$. We can show that this would result from equality in 5.4 (iii) when $w^{\prime} u=w_{\lambda}$. Unfortunately we were not quite able to establish the latter; but to illustrate our method we give a new proof of [3] (Folg. 2.20). First we note an easy and well-known consequence of the fact that $\mathscr{J} \mathscr{H} \mathrm{M}\left(w_{\lambda} \lambda\right)$ is multiplicity free.

Lemma. - Set $\mathrm{B}_{\lambda}=\{\alpha, \beta\}$. Then

$$
\overline{\mathbf{M}\left(w_{\lambda} s_{\alpha} \lambda\right)}=\overline{\mathbf{M}\left(w_{\lambda} s_{\beta} \lambda\right)}=\mathbf{M}\left(w_{\lambda} s_{\alpha} \lambda\right) \cap \mathbf{M}\left(w_{\lambda} s_{\beta} \lambda\right)
$$

Remark. - When $\mathrm{B}_{\lambda}$ is of type $\mathrm{A}_{1} \times \mathrm{A}_{1}$ or $\mathrm{A}_{2}$, this also follows from [13] (Lemma 1).
7.2. Corollary. $-I_{\alpha}^{*}=I_{\beta}, I_{\beta}^{*}=I_{\alpha}$.

By definition $I_{\alpha} \subset I_{\beta}^{*}$. For the opposite inclusion, note that $I_{\beta}^{*} \subset I_{\alpha}+I_{\beta}$ by 4.4 (i) and 4.5 and so $I_{\beta}^{*}=I_{\beta}^{*} \cap I_{\beta}+I_{\alpha}$. By 4.4 (iii) taking $B^{\prime}=\{\beta\}$, we have $I_{\beta}^{*} \cap I_{\beta} \mp I_{\beta}$ and so by 3.5 (i) and 5.1 (i) it follows that $\left(\mathrm{I}_{\beta}^{*} \cap \mathrm{I}_{\beta}\right) \mathbf{M}\left(w_{\lambda} \lambda\right) \subset \overline{\mathrm{M}\left(w_{\lambda} s_{\beta} \lambda\right)} \subset \mathbf{M}\left(w_{\lambda} s_{\alpha} \lambda\right)$, by 7.1. Then by $4.6, \mathrm{I}_{\beta}^{*} \mathrm{M}\left(w_{\lambda} \lambda\right) \subset \mathrm{M}\left(w_{\lambda} s_{\alpha} \lambda\right)$ and so $\mathrm{I}_{\beta}^{*} \subset \mathrm{I}_{\alpha}$, by 4.7.

Remark. - It is clear that this result is equivalent to [3] (Folg. 2.20).
7.3. Set $\mathrm{B}_{\lambda}=\{\alpha, \beta\}$ and choose $l \in\left\{2,3, \ldots,(1 / 2)\right.$ card $\left.\mathrm{W}_{\lambda}-1\right\}$. Then there are exactly two distinct elements $w, w^{\prime} \in \mathrm{W}_{\lambda}$ satisfying $l_{\lambda}(w)=l_{\lambda}\left(w^{\prime}\right)=l$. Furthermore

Lemma (notation 5.1) :
(i) $\mathrm{J}_{w}+\mathrm{J}_{w^{\prime}}=\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\beta}\right)^{l-1}$;
(ii) $\mathrm{J}_{w} \cap \mathrm{~J}_{w^{\prime}}=\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\beta}\right)^{l}$;

Clearly $\left(I_{\alpha} \cap I_{\beta}\right) \supset I_{\alpha} I_{\beta}+I_{\beta} I_{\alpha}$ and any non-zero simple subquotient $V$ of

$$
\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\beta}\right) /\left(\mathrm{I}_{\alpha} \mathrm{I}_{\beta}+\mathrm{I}_{\beta} \mathrm{I}_{\alpha}\right)
$$

must satisfy LAnn $V=I_{\alpha}+I_{\beta}$. Then by $4.3,4.4$ (i) and $4.5, V=V(-\lambda,-\lambda)$ up to isomorphism which contradicts the fact that $\left(I_{\alpha} \cap I_{\beta}\right)$ does not admit the trivial $\mathfrak{f}$ submodule. This gives (i) for $l=2$ and the general case obtains by taking powers. Again $\mathrm{J}_{w} \cap \mathrm{~J}_{w^{\prime}} \supset\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\beta}\right)^{l}$ and $\mathrm{I}_{\alpha}\left(\mathrm{J}_{w} \cap \mathrm{~J}_{w^{\prime}}\right) \subset \mathrm{J}_{w s_{\alpha}} \cap \mathrm{J}_{w^{\prime} s_{\alpha}} \subset\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\beta}\right)^{l}$ by (i). Thus a similar argument gives (ii).
7.4. Set $\mathrm{B}_{\lambda}=\{\alpha, \boldsymbol{\beta}\}$ and define $k$ as in 2.3.

Proposition. - Suppose $k=0,1,2$. Then $\mathscr{J} \mathscr{H} \mathrm{L}(-\lambda,-\lambda)$ is multiplicity free. Suppose $B_{\lambda}$ is of type $B_{2}$. We show (see Fig.) that

$$
\left\{\mathrm{J}_{w}: w \in \mathrm{~W}_{\lambda}, \mathrm{I}_{\alpha}+\mathrm{I}_{\beta},\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\beta}\right)^{l}: l=1,2,3\right\}
$$

is the set of non-zero $U$ submodules of $U(\mathfrak{g}) / I_{\lambda}$. By 5.1 (i), (iv) and 7.3, these are pairwise distinct and satisfy the given inclusion relations. We show that each arrow defines a simple quotient. By 4.4 (i) and $4.5, \mathrm{I}_{\alpha}+\mathrm{I}_{\beta}$ is the unique maximal submodule. By [7] (II), there exists a unique minimal submodule which by 5.3 (i) is $\mathrm{L}\left(-w_{\lambda} \lambda,-\lambda\right)$ and this by the argument of 7.3 (i) and 4.10 (iii) equals $\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\beta}\right)^{3}$. By 7.3 and $\alpha, \beta$ interchange it suffices to prove simplicity for the arrows labelled $1,2,3$. For 1 , this follows from 7.2 and 4.4 (iii). Consider 2. By 3.1 (iv) and 3.4 any simple subquotient of $\mathrm{I}_{\alpha} \mathrm{I}_{\beta} /\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\beta}\right)^{2}$ is isomorphic to $\mathrm{V}(-w \lambda,-\lambda)$ for some $w \in \mathrm{~W}_{\lambda}$. Taking 4.3 into account it follows from 7.2 that

$$
\operatorname{Ann} \mathrm{V}(-w \lambda,-\lambda)=\check{\mathrm{I}}_{\beta} \otimes \mathrm{U}(\mathfrak{g})+\mathrm{U}(\mathrm{~g}) \otimes \check{\mathrm{I}}_{\alpha} .
$$

Substitution in 5.2 gives $w=s_{\beta} s_{\alpha}$. Yet $\mathrm{I}_{\alpha} \mathrm{I}_{\beta}=\mathrm{L}\left(-s_{\beta} s_{\alpha} \lambda,-\lambda\right)$ by 5.1 (i) and so by 3.1 (iv), $\mathrm{V}\left(-s_{\beta} s_{\alpha} \lambda,-\lambda\right)$ can only occur once in $\mathrm{I}_{\alpha} \mathrm{I}_{\beta} /\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\beta}\right)^{2}$ which is hence simple. Consider 3. Let $\mathrm{V}(-w \lambda,-\lambda): w \in \mathrm{~W}_{\lambda}$ be a simple subquotient of $\mathrm{I}_{\alpha} \mathrm{I}_{\beta} \mathrm{I}_{\alpha} /\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\beta}\right)^{3}$. Then Ann $V(-w \lambda,-\lambda)=\check{I}_{\beta} \otimes \mathrm{U}(\mathrm{g})+\mathrm{U}(\mathrm{g}) \otimes \check{\mathrm{I}}_{\beta}$ and so by $5.2, w=s_{\alpha}$ or $w=s_{\alpha} s_{\beta} s_{\alpha}$. The former choice contradicts [7] (Prop. 4) and the latter implies the simplicity of $\mathrm{I}_{\alpha} \mathrm{I}_{\beta} \mathrm{I}_{\alpha} /\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\beta}\right)^{3}$ as above.

The submodules of $U(g) / I_{\lambda}$ and their inclusion relations for $B_{\lambda}$ of type $B_{2}$. The notation $\mathrm{M} \rightarrow \mathrm{N}$ denotes $\mathrm{M} \supset \mathrm{N}$ with $\mathrm{M} / \mathrm{N}$ a simple U module.
$4^{e}$ série - tome $10-1977-\mathrm{N}^{\circ} 4$

By 4.4 (i) and $4.5, \mathrm{I}_{\alpha}+\mathrm{I}_{\beta}$ admits exactly two simple quotients. By 7.3 (i) and 3.1 (ii) the same is true of the $\left(\mathrm{I}_{\alpha} \cap \mathrm{I}_{\beta}\right)^{l}: l=1,2$. By 3.1 (ii) and 5.1 (i) the $\mathrm{J}_{w}: w \in \mathrm{~W}_{\lambda}$ admit exactly one simple quotient. Since each arrow defines a simple subquotient it follows that there can be no other submodules of $U(\mathfrak{g}) / I_{\lambda}$ than those given in the Figure.

Then by [7] (Prop. 4), or by direct computation it follows that $\mathscr{J} \mathscr{H} \mathrm{L}(-\lambda,-\lambda)$ is mulitplicity free for $\mathrm{B}_{\lambda}$ of type $\mathrm{B}_{2}$ (i. e. when $k=2$ ). The remaining cases follow similarly.

Remarks. The cases $k=0,1$ are unpublished results of Duflo. In genera ${ }^{1}$ $\mathscr{J} \mathscr{H} \mathrm{L}(-\lambda,-\lambda)$ is not multiplicity free if card $\mathrm{B}_{\lambda} \geqq 3$ (cf. [5], 7.1 and [7], Cor. 1 to Prop. 11). Recalling 4.6 and 5.1 one can also easily verify that the conclusion of the proposition implies that the map $\mathrm{I} \mapsto \mathrm{IM}\left(w_{\lambda} \lambda\right)$ is a bijection of $\mathbf{J}\left(\mathrm{U}(\mathrm{g}) / \mathrm{I}_{\lambda}\right)$ onto the set of submodules of $\mathbf{M}\left(w_{\lambda} \lambda\right)$ (cf. [8], Prob. 30). It would be important to show that this holds in general and we remark that the counterexample to surjectivity given in [13], Ex. 1 , is for $\lambda$ non-regular. More generally if $B_{\lambda}$ is of type $A_{2}$ (resp. $B_{2}$ ) with $\lambda$ on exactly one wall (i.e. subregular) then similar calculations show that card $\mathbf{J}\left(\mathbf{U}(\mathfrak{g}) / I_{\lambda}\right)=2$ (resp. 3) whereas after Jantzen [14], $M\left(w_{\lambda} \lambda\right)$ admits 3 (resp. 4) distinct proper submodules.
