COMPUTATIONAL COMPLEXITY

On the geometry of polynomials
and a theory of cost:

Part I

BY MIKE SHUB AND STEVE SMALE (*)

The main goal of this paper is to show that the number of iterations required for a
certain fast algorithm to find a zero of a complex polynomial of degree $d$, is linear in $d$,
provided that an arbitrarily small set of problems is excluded.

The algorithm which does this is an “incremental” version of that of Newton and
Euler.

This result is part of a broad study of algorithms for polynomial root finding. Our
work could also be considered as an investigation into the geometry of a complex
polynomial $f$. This geometry is especially concerned with the foliation of the complex
numbers $\mathbb{C}$ defined by the lifting of rays by $f^{-1}$. This curve family branches at the
critical points $\theta$ of $f$ and constitutes solutions to Newton’s differential equation

$$\frac{dz}{dt} = -\frac{f(z)}{f'(z)}.$$

Let $P_d(1)$ be the set of polynomials $f(z) = z^d + a_{d-1} z^{d-1} + \ldots + a_1 z + a_0$ satisfying
$|a_i| \leq 1$. Let $S_k^d$ be the set of complex numbers $z_0$ with $|z_0| = R$ and $D_k^d$ be the set of
complex numbers $z_0$ with $|z_0| \leq R$. Impose Lebesque measure on $S_k^d \times P_d(1)$ or
$D_k^d \times P_d(1)$ normalized to total measure 1. An approximate zero of a polynomial $f$ is a
complex $z$ for which Newton’s (and Euler’s) method converges in a very strong sense
(see the Corollary to Theorem 1). As a consequence of Proposition 3 of section 2 one
has that the measure of the set of $(z, f)$ in $D_k^d \times P_d(1)$ such that $z$ is an approximate
zero of $f$ is greater than $c/d^5$ where $c$ is about $1/1,000$. This gives an answer to Problem
7 Smale.

(*) Both authors received partial support from the N.S.F.
Main Theorem. — Given $0 < \mu < 1$, $d > 1$, there is an $R = R(\mu, d) > 0$ and an iterative algorithm $E = E(\mu, d)$ such that for $(z_0, f)$ in $S^2 \times \mathcal{P}_d(1)$, with probability $1 - \mu$, and

$$s = L_1 d \left( \frac{|\log \mu|}{\mu} \right)^{1 + (1/\log d)} + L_2,$$

then $z = (E)^4(z_0)$ is an approximate zero.

Here $L_1, L_2$ are constants, $L_1$ less than 20, $L_2$ smaller yet, and $E(\mu, d)$ is a variation of an algorithm that was used by Euler. It is robust and executed with relatively small cost.

The $s$ is the number of steps in the iteration. The main feature of this result is the good estimate for $s$. It is already difficult to obtain any polynomial bound (in Smale, a result is obtained using Newton’s method with $d^9$; this reference also gives some background to our paper here).

The algorithm $E(\mu, d)$ is incremental Euler $E_k$ where we give the increment $h$ as an explicit function of $\mu, d$. It is noteworthy that the $k$ depends on $d$ and is simply the smallest integer greater than $\log d$. From the definition of $E_k$, $k$ is the number of derivatives evaluated at each step and so depends on $d$ simply. The idea perhaps could be useful in the practice of equation solving.

One problem the result poses is why choose $|z_0| = R$ which grows like $d$ and contributes the factor $d$ in the estimate of $s$? It would seem that choosing $|z_0| \leq 1$ is more sensible, but the corresponding analysis becomes especially difficult.

As it stands now the above theorem, besides requiring the long proof below, depends on mathematics related to the Bieberbach conjecture. The Bieberbach conjecture itself would only slightly improve the constants in the result.

The main theorem of this paper does not distinguish between the intrinsic difficulty of finding an approximate zero for a particular $f$, and the difficulty of finding a good starting point $z_0$ for $f$. In part II of this paper we will separate these problems and show that the $k$-th incremental Euler algorithms may be adapted to produce probabilistic and deterministic algorithms for finding approximate zeros for $f \in \mathcal{P}_d(1)$ with the average number of steps and arithmetic operations required $O(d \log d)$ and $O(d^2 \log d)$ respectively.

Section 1

An incremental algorithm is given by a map

$$I_{k, f} : S^2 \to S^2, \quad z' = I_{k, f}(z) = I(z),$$

parameterized by $0 \leq h \leq 1$ and complex polynomials $f$. Here $S^2$ denotes the Riemann sphere of complex numbers. We suppose always that

$$I_{0, f}(z) = z$$
and so $I_{h,f}$ is a parameterized family of algorithms starting at the identity. Eventually continuity conditions will be put on $I$.

To solve $g(z)=0$ by using an incremental algorithm $I_{h,f}$, one lets $z_0$ be a complex number, and chooses $h$ appropriately. In a number of situations, the sequence

$$z_n = I_{h,g}(z_{n-1}) = h_{h,g}(z_0), \quad n = 1, 2, 3, \ldots,$$

will converge to a solution of $g(z)=0$.

Most of our examples of incremental algorithms are derived from some standard iterative process or scheme for solving either non-linear systems or ordinary differential equations. We frequently call the maps $I_{h,f}$ iterative or iteration processes or schemes. We will sometimes assume $f(z) \neq 0$, and $f'(z) \neq 0$ when the context requires it, for example to be sure we are not dividing by zero below.

**Example 1.** — Incremental Newton’s method (see Smale for background)

$$I_{h,f}(z) = z - \frac{hf(z)}{f'(z)}.$$  

The special case $N(z) = z - f(z)/f'(z)$ (for $h=1$) is Newton’s method.

**Example 2a.** — Derived from $k$-th order Taylor’s method, $k = 1, 2, \ldots$ (see Atkinson)

$$I(z) = z + \sum_{i=1}^{k} \frac{d^i}{dt^i} \left( \frac{\varphi_i(z)}{i!} \right)_{t=0} h^i,$$

where $\varphi_i(z)$ is the solution of the differential equation

$$\frac{dz}{dt} = -\frac{f(z)}{f'(z)} = F(z),$$

with initial condition $\varphi_0(z) = z$.

The quantities $(d^i/dt^i) \varphi_i(z)_{t=0}$ are of course computable from $F$ and its derivatives. Examples 2a and Example 1 coincide. Example 2a is explicitly given by:

$$I(z) = z + F(z) \left( h + \frac{h^2}{2} F'(z) \right); \quad F' = \frac{f'' f}{(f')^2} - 1.$$

Example 2a is:

$$I(z) = z + F(z) \left[ h + \frac{h^2}{2} F'(z) + \frac{h^3}{3} ((F'(z))^2 + F''(z) F(z)) \right].$$

We continue to write

$$F \quad \text{for} \quad \frac{f}{f'}.$$
Example 3. — (derived from simple Runge-Kutta; see Atkinson)

\[ I(z) = z + \frac{h}{2 F(z)} [F(z) + F(z + hF(z))]. \]

Example 4. — We have taken this algorithm from Durand, p. 25 ff., where it appears with \( h = 1 \)

\[ I(z) = z - \frac{hf(z)f'(z)}{(f'(z))^2 - (1/2) hf'(z) f''(z)} = z + F(z) \left( \frac{h}{1 - (1/2) h [F(z) f''(z)/(f'(z))^2]} \right). \]

In Durand, p. 69 it is pointed out that this iterative method (with \( h = 1 \)) has order 3 for simple zeros.

The following construction is important for the next example and is also used throughout our analysis.

Given a polynomial \( f \) and a point \( z \) such that \( f'(z) \neq 0 \), denote the map given by a power series for example, which takes \( f(z) \) to \( z \) and is a compositional inverse to \( f \) by \( f^{-1} \). Note as in Smale that the radius of convergence \( r = r(f, z) \) of \( f^{-1} \) is \( |f(z) - f(\theta_*)| \) for some \( \theta_* \) such that \( f'(\theta_*) = 0 \). Thus \( f^{-1}_*: \Delta_r(f(z)) \to \mathbb{C} \) is an injective analytic function sending \( f(z) \) to \( z \), where \( \Delta_r(f(z)) \) is the disk of radius \( r \) about \( f(z) \). It is a “branch” of \( f^{-1} \).

If \( f'(z) = 0 \), let \( r(f, z) = 0 \).

If \( f(z) \neq 0 \) define \( h_1 = h_1(f, z) = r(f, z)/|f(z)| \). Thus

\[ h_1(f, z) \geq \min_{\theta : f' = 0} \frac{|f(z) - f(\theta)|}{|f(z)|}. \]

If \( \theta_*=\theta_*(f, z) \) is one of the critical points \( \theta \) for which \( r = |f(z) - f(\theta_*)| \), then

\[ h_1(f, z) = \frac{|f(z) - f(\theta_*)|}{|f(z)|}. \]

Example 5. — Incremental Euler, \( k = 1, 2, \ldots, \infty \).

This is our most important example and we take some time to develop it carefully. The evidence of this paper suggests it is the most appropriate for practically computing zeros of complex polynomials.

If \( h < h_1(f, z) \) we may solve the equation

\[ \frac{f(z')}{f(z)} = 1 - h, \]

by setting \( z' = f^{-1}_z((1 - h) f(z)) \).
Expanding around \( f(z) \), (Taylor’s Series) we obtain

\[
E_\infty(z) = z = z + \sum_{i=1}^{\infty} \frac{(f^{-1}_z) f^{(i)}(z)}{i!} (-hf(z))^i.
\]

Evaluation of \((5_\infty)\) is usually computationally infeasible, so we truncate. Let \(\tau_d\) be the operation of truncating a power series,

\[
\tau_d \left( \sum_{i=0}^{\infty} a_i h^i \right) = \sum_{i=0}^{d} a_i h^i.
\]

The \( k \)-th incremental Euler \( E_k \) or \( E_k(b, f) \) is given by

\[
E_k(z) = \tau_k \left( \frac{f_z^{-1}}{h} ((1-h) f(z)) = z + \sum_{i=1}^{k} \frac{(f^{-1}_z) f^{(i)}(z)}{i!} (-hf(z))^i. \right)
\]

We end our discussion of this example by a series of remarks:

1. Suppose \( h > 1 \). Then one can put \( h=1 \) in \((5_{\infty})\) to obtain a power series representation of a solution to \( f(z) = 0 \).

2. One can easily write down

\[
E_4(z) = z - \frac{f(z)}{f'(z)} \left( h - \sigma_2 h^2 + (2 \sigma_2^2 - \sigma_3) h^3 + (5 \sigma_2^3 - 5 \sigma_2 \sigma_3 + \sigma_4) h^4 \right),
\]

adapting the computations of Durand, p. 5 and using

\[
\sigma_i = (-1)^{i-1} \frac{f^{(i)}(z)}{i! (f'(z))^i}.
\]

Note that by keeping only the first \( k \) powers of \( h \), \( k = 1, 2 \) or 3, we obtain \( E_k \) for those values. In particular \( E_4 \) is just incremental Newton of Example 1.

In the literature the algorithms \( E_k \) with \( h=1 \) are sometimes accredited to Euler and sometimes to Shroeder. According to Durand, the case \( E_{\infty} \) with \( h=1 \) was reasoned by Euler. On the other hand both Henrici and Householder refer to Shroeder for algorithms which seem to amount to \( E_k \) with \( h=1 \). Ostrowski says that the power series for the solution goes back to Newton and Euler. Euler in his Caput IX, De Usu Calculi Differentialis in Aequationibus Resolvendis writes, p. 428:

"Siigitur \( f \) ponatur designare istum ipsius \( x \)
valorem quod erit radix aequationis \( y=0 \), quoniam
\( x \) abit in \( f \), si statuat \( y=0 \), erit per ea,
quae supra [§ 67] sunt demonstrata,

\[
f = x - y \frac{dx}{dy} + \frac{y^2}{2} \frac{d^2x}{dy^2} - \frac{y^3}{6} \frac{d^3x}{dy^3} + \frac{y^4}{24} \frac{d^4x}{dy^4} - \text{etc.},
\]

In qua aequatione statuitor differentiale \( dy \) constans."

ANNALES SCIENTIFIQUES DE L’ÉCOLE NORMALE SUPÉRIEURE
which gives the power series solution for the root and is exactly $E_\infty$ with $h=1$. Euler goes on to solve equations iterating $E_k$ with $h=1$ up to $k=5$. We have thus called the algorithms $k$-th (incremental) Euler and denoted them $E_k$. Shroeder gives a much more systematic and modern treatment of these algorithms, dealing with such questions as convergence and order.

In the thesis of Gregg Saunders, these and related algorithms are studied from a little different point of view.

Next we generalize examples $5_k$.

**Example 6_k.** — Generalized Incremental Euler.

First suppose $c_1 > 0$, $c_2$, ..., $c_k$ are given real parameters. Let $P(h) = c_1 h + c_2 h^2 + \ldots + c_k h_k$. Then if $h$ is small enough so that $|P(h)| < h_1$, we may solve

$$\frac{f(z')}{f(z)} = 1 - P(h) \quad \text{by} \quad z' = f^{-1}_z((1 - P(h))f(z)).$$

This motivates

$$(6_k) \quad G_{E_{P_k}} f(z) = G_{E_k} f(z) = \tau_k f^{-1}_z((1 - P(h))f(z)),$$

or

$$G_{E_k} f(z) = z + \tau_k \sum_{l=1}^{\infty} \frac{(f^{-1}_z)^{(l)}(z)}{l!}((-P(h)f(z))^l).$$

Clearly $(5_k)$ is the special case of $(6_k)$ obtained by setting $c_1 = 1$, $c_i = 0$, $i > 1$. Moreover example $2_k$ (derived from $k$-th order Taylor’s method) is obtained by putting $c_i = (-1)^{i-1}/i!$, $i = 1, \ldots, k$. This may be seen as follows.

Let $\varphi_i(z)$ be the solution of the differential equation $dz/dt = -f(z)/f'(z)$ with initial condition $\varphi_0(z) = z$. Then it is easy to see that

$$f(\varphi_i(z)) = e^{-i} f(z)$$

and thus the $k$-th order Taylor expansion of $\varphi_i(z)$ is given by

$$\tau_k f^{-1}_z(e^{-i} f(z)) = z + \tau_k \sum_{i=1}^{\infty} \frac{(f^{-1}_z)^{(i)}(z)}{i!} \left( \sum_{i=1}^{\infty} \frac{(-t)^i}{i!} f(z) \right)^i,$$

where the derivatives of $f^{-1}_z$ are evaluated at $f(z)$.

Returning to the general case, we may express

$$G_{E_k} f(z) = z + F \sum_{j=0}^{k-1} P_j h^{j+1},$$

where $P_j$ are polynomials in the $c_i$ and $\sigma_i$, where $\sigma_i$ is defined above.
**Proposition 1:**

\[ P_0 = c_1, \]
\[ P_1 = c_2 - \sigma_1 c_1^2, \]
\[ P_2 = c_3 - 2\sigma_2 c_1 c_2 - (\sigma_3 - 2\sigma_2^2) c_1^3 \]

and \( P_k = P_k(\sigma_1, \ldots, \sigma_{k+1}, c_1, \ldots, c_{k+1}) \) has the property: in each term the subscripts of \( c_i \), \( \sigma_j \) times the powers to which they are raised sum to \( k \) less the number of factors. One can write down \( P_k \) explicitly inductively, in terms of \( P_i \) \( i < k \), \( \sigma_{k+1} \) and \( c_{k+1} \).

The easiest way to prove this proposition is to make a little detour. Introduce the polynomial \( \sigma(w) = \sum_{i=1}^{d} \sigma_i w_i \) where as above

\[ \sigma_i = (-1)^{i-1} \frac{f^{(i)}(z) (f(z))^{i-1}}{i!(f'(z))^i} \]

and \( f \) has degree \( d \). This polynomial will be useful later. Note that \( \sigma(0) = 0 \) and \( \sigma'(0) = 1 \). If we write an incremental algorithm

\[ z' = I_{h, f}(z) \quad \text{as} \quad z' = I_{h, f}(z) = z + FR(h, f, z). \]

Then by Taylor Series

\[ f(z') = f(z) + \sum_{i=1}^{d} \frac{f^{(i)}(z) (z' - z)^i}{i!} = f(z) + \sum_{i=1}^{d} \frac{f^{(i)}(z) F^i R^i}{i!} = f(z) - f(z) \sum_{i=1}^{d} \sigma_i R^i. \]

Thus:

**Proposition 2:**

\[ \frac{f(z')}{f(z)} = 1 - \sigma \circ R \quad \text{where} \quad R = \frac{I_{h, f}(z) - z}{F}. \]

We apply this to an example.

For

\[ I_{h, f} = E_{\infty} (h, f) \quad \frac{f(z')}{f(z)} = 1 - h = 1 - \sigma \circ R. \]
Thus $h = \sigma \circ R$. Since $\sigma(0) = 0$ and $\sigma'(0) = 1$, $\sigma$ is invertible on some disk to $\sigma^{-1}$ with $\sigma^{-1}(0) = 0$ and $(\sigma^{-1})'(0) = 1$. Thus we have

$$\sigma^{-1}(h) = R = \frac{1}{F} \sum_{i=1}^{\infty} \frac{(f^{-1}_x)^{(0)}(0)}{l!} (-f(z))^i h^i.$$ 

If we expand $\sigma^{-1}$ around 0

$$\sigma^{-1}(h) = \sum_{i=1}^{\infty} \frac{(\sigma^{-1})^{(0)}(0)}{i!} h^i,$$

it follows that $(\sigma^{-1})^{(0)}(0) = (1/F) (f^{-1}_x)^{(0)}(0)(-f(z))^i$ and thus $\sigma^{-1}$ is defined and injective on the open disk of radius $h_1$ around 0.

Now we return to Proposition 1.

$$GE_k(z) = z + \tau_k \sum_{i=1}^{\infty} \frac{(f^{-1}_x)^{(0)}(0)(-f(z))^i}{l!} (P(h))^i = z + F \tau_k \sum_{i=1}^{\infty} \frac{(\sigma^{-1})^{(0)}(0)}{l!} (P(h))^i.$$ 

Now the proof of the Proposition is easily seen by applying inductive formulas for the coefficients of the inverse of a power to $\sigma$ see Durand, p. 4 and formulas for composition, see Henrici.

Our study of incremental algorithms focuses on $f(z')/f(z)$ and its Taylor expansion in $h$. This “target space” approach becomes clearer as the paper develops.

The idea is to consider the curve $h \to f(I_h, f(z))$ in the target space for small positive $h$. For an ideal algorithm, for all $f$ and $z$, as $h$ increases from 0, $f(I_h, f(z))$ moves along the ray from $f(z)$ to 0. No practical incremental algorithm accomplishes this, but one of the main results of this paper is that some algorithms do this infinitesimally up to any order of contact at $f(z)$ and with a certain uniformity. This motivates the following definition which measures the efficiency of an incremental algorithm.

An incremental algorithm $I_h, f$ will be said to be of efficiency $k$ provided: there exist real constants $\delta > 0$, $K > 0$, $c_1$, $\ldots$, $c_k$, $c_1 > 0$ independent of $h$, $f$ and $z$ such that

$$\frac{f(I_h, f(z))}{f(z)} = 1 - (c_1 h + c_2 h^2 + \ldots + c_k h^k) + S_{k+1}(h),$$

where $|S_{k+1}(h)| \leq K h^{k+1} \max(1, 1/h^2)$ for $0 < h \leq \delta (\min(1, h_1))$ and $h_1 = h_1(f, z)$ is defined as above.

In this case we also simply say that the iteration $I_h, f$ is of efficiency $k$.

In section 2, we will show that $E_k$ is of efficiency $k$. In section 3 we use this fact to track the iterates of $E_k$ in the target space. Later we characterize the incremental algorithms of efficiency $k$. It will follow that all of the above examples are of efficiency $k$, for appropriate $k$. Moreover, the set of all (small) incremental algorithms which are polynomials in $h$ of degree $k$ and of efficiency $k$ are precisely those of Example $6_k$. 

4e série – tome 18 – 1985 – n° 1
The goal of this section is to prove:

**Theorem 1.** For any \( k \), \( 0 < k \leq \infty \), the incremental \( k \)-th Euler algorithm (example 5 of section 1) is of efficiency \( k \). More precisely, there is a universal constant \( 1 \leq B \leq 1.07 \), and for any polynomial \( f \), complex number \( z \) with \( f'(z) \neq 0 \), \( f(z) \neq 0 \), \( z' = E_k(z) = E_k^{(1)}(h, f) \)

\[
\frac{f(z)}{f(z)} = 1 - h + Q(h, f, z) \frac{h^{k+1}}{h_1}, \quad |Q| \leq \beta_k(\gamma),
\]

where

\[
\beta_k(\gamma) = \frac{B(k + 1)(1 - \gamma)^2}{[(1 - \gamma)^2 - 4\gamma][(1 - \gamma)^2 - 4\gamma(1 + B(k + 1)\gamma)]}.
\]

Here \( \gamma = h/h_1 \) is assumed to satisfy \( 0 < \gamma < \gamma_k \) where \( \gamma_k \) is the first positive number for which the denominator of \( \beta_k(\gamma) \) vanishes. Otherwise said, \( 0 < h < \gamma_k h_1 \). Here \( h_1 = h_1(f, z) \) is the function defined in section 1.

We first give a proof of Theorem 1. At the end of the section is some discussion and the first implication of the theorem.

We recall some results from the theory of Schlicht functions, related to the Bieberbach conjecture, Duren. One relation to our work comes from the fact that if \( f \) is a polynomial, then \( f^{-1} \) is defined and injective on the disc of radius \( r(f, z) \) about \( f(z) \).

An analytic function \( f : D_1 \to \mathbb{C} \) defined on the unit disc, given by the power series

\[
f(z) = \sum_{i=1}^{\infty} a_i z^i
\]

is called Schlicht if it converges, \( a_1 = 1 \), and is one to one for \( |z| < 1 \). Under these conditions there is the classic:

**Bieberbach Conjecture.** \( |a_l| \leq l \), \( l = 2, 3, \ldots \).

In fact \( |a_2| \leq 2 \) (Bieberbach), \( |a_3| \leq \delta \) (Loewner), \( |a_i| \leq i \) for \( i \leq 6 \) (see Duren for the references).

**Bieberbach-Koebe Theorem.** See Hille. The image of a schlicht function contains a disc of radius \( 1/4 \) around 0.

**Theorem of Littlewood.** See Hille.

\[
|a_n| \leq ne \quad (e = 2.71 \ldots).
\]

**Improved Theorem of Littlewood.** See Duren.

\[
|a_n| \leq 1.07 n.
\]

**Loewner Theorem.** See Hayman. If \( g(w) = w + b_2 w^2 + b_3 w^3 + \ldots \) is the inverse of a schlicht function expressed as a power series near zero, then

\[
|b_i| \leq 2^{i+1} \frac{1.3 \ldots (2i-1)}{1.2 \ldots (i+1)} \leq 4^{i-1}.
\]
Finally we state:

**Distortion Theorem of Koebe and Gronwall.** — See Hayman, Hille. If \( f \) is schlicht then

\[
\frac{r}{(1+r)^2} \leq |f'(z)| \leq \frac{r}{(1-r)^2}, \quad \text{for} \quad |z| \leq r,
\]

\[
\frac{1-r}{(1+r)^2} \leq |f'(z)| \leq \frac{1+r}{(1-r)^2}, \quad |z| \leq r,
\]

these are sharp bounds.

We use \( B \) to indicate the best number between 1 and 1.07 (Improved Littlewood Theorem) such that \(|a_i| \leq iB\) for all \( i \). Thus \( B = 1 \) if the Bieberbach conjecture is true. Recall that \( \tau_k \) is truncation. Our main tool in proving Theorem 1 is the following Proposition.

**PROPOSITION 1.** — Suppose that \( f \) is schlicht and \( g \) is its inverse. Then

\[
|g(f(z)) - g(\tau_k f(z))| \leq \frac{\gamma^{k+1} (1-\gamma)^2 B \kappa}{[(1-\gamma)^2 - 4 \gamma][(1-\gamma)^2 - 4 \gamma (1 + B \kappa)]}
\]

where \( \gamma = |z| \), for \( \gamma \) less than the first positive root of the denominator.

We use a sequence of lemmas.

**LEMMA 1.** — For \(|x| < 1\), \( l_0 \geq 1\)

\[
\sum_{i=l_0}^{\infty} lx^{i-1} \leq \frac{l_0 x^{l_0 - 1}}{(1-x)^2}.
\]

**Proof:**

\[
\sum_{i=l_0}^{\infty} lx^{i-1} = \sum_{i=1}^{\infty} lx^{i-1} - \sum_{i=0}^{l_0 - 1} lx^{i-1} = \left( \frac{1}{1-x} \right)^r \left( \frac{1-x^{l_0}}{1-x} \right) = \frac{x^{l_0-1} (l_0 - (l_0 - 1)x)}{(1-x)^2} \leq \frac{l_0 x^{l_0 - 1}}{(1-x)^2}.
\]

**Q.E.D.**

**LEMMA 2.** — Let \( g(x) = \sum b_i z^i \) be a convergent power series with \( b_0 = 0 \) and \(|b_1| = 1\). Let \( a = \max_{i \geq 1} |b_i|^{1/(i-1)} \). Then

\[
\left| \frac{g^{(l)}}{l!} (x) \right| \leq a^{l-1} \left( \frac{1}{1-a |x|} \right)^{l+1} \quad \text{for} \quad |x| < \frac{1}{a}.
\]

**Proof.** — Note

\[
g^{(l)}(x) = \sum_{j=1}^{\infty} j(j-1) \ldots (j-l+1) b_j x^{j-l}
\]
and
\[ |g^{(l)}(x)| \leq \sum_{j=l}^{\infty} j(j-1) \ldots (j-l+1) a^{j-l-1} x^{j-l}. \]

So if \( y = a |x| < 1 \), then
\[ |g^{(l)}(x)| \leq a^{l-1} \sum_{j=0}^{\infty} j(j-1) \ldots (j-l+1) y^{j-l} \]
\[ \leq a^{l-1} \frac{d}{dy} \sum_{j=0}^{\infty} y^{j} \frac{d}{dy} a^{j-1} \frac{1}{1-y} \]
\[ \leq a^{l-1} \frac{l!}{(1-y)^{l+1}}. \]

Divide by \( l! \)!

**Q.E.D.**

**Lemma 3.**  Let \( g(w) = \sum b_{i} w^{i} \) be a convergent power series with \( b_{0} = 0 \), \( |b_{1}| = 1 \) and let \( a = \max_{i>1} |b_{i}|^{1/(i-1)} \). Let \( x, w \in \mathbb{C} \), and \( b, c \) be positive numbers. Suppose \( (1+c) ab < 1 \), \( |x| \leq b \), \( |w-x| \leq bc \).

Then
\[ |g(w) - g(x)| \leq \frac{bc}{(1-ab)(1-((1+c) ab)).} \]

**Proof.** Consider the Taylor expansion of \( g \) at \( x \)
\[ g(w) - g(x) = \sum_{i=0}^{\infty} g^{(i)}(x) \frac{(w-x)^{i}}{i!}. \]

Apply Lemma 2 to obtain
\[ |g(w) - g(x)| \leq \sum_{i=1}^{\infty} a^{i-1} \left( \frac{1}{1-a|x|} \right)^{i+1} |w-x|^i \]
\[ \leq \sum_{i=1}^{\infty} a^{i-1} \left( \frac{1}{1-a|x|} \right)^{i+1} (bc)^i \left( \frac{1}{1-a|x|} \right)^{2} (bc) \sum_{i=1}^{\infty} \left( \frac{abc}{1-a|x|} \right)^{i-1} \]
\[ = bc \left( \frac{1}{1-a|x|} \right)^{2} \left( \frac{1}{1-(abc/(1-a|x|))} \right) = \left( \frac{bc}{1-a|x|} \right) \left( \frac{1}{1-a|x|} \right) \left( \frac{1}{1-a|x| - abc} \right). \]

**Q.E.D.**

Now we can give the proof of Proposition 1. Let \( f(z) = \sum_{i=1}^{\infty} a_{i} z^{i} \). By the Koebe-Gronwall Distortion Theorem,
\[ |f(z)| \leq \frac{\gamma}{(1-\gamma)^{2}} \quad \text{where} \quad \gamma = |z|. \]
Then
\[ |f(z) - \tau_k f(z)| \leq \sum_{j=k+1}^{\infty} |a_j| \gamma^j \leq B \sum_{j=k+1}^{\infty} j \gamma^j,\]
by the extended Littlewood Theorem where \(1 \leq B \leq 1.07\). In turn this is less than \((B(k+1)\gamma^{k+1})(1-\gamma)^2\) by Lemma 1.

Now we apply Lemma 3, where we may take \(a=4\) by the Loewner estimate. Let \(c = B\gamma^k(k+1)\) and \(b = \gamma/(1-\gamma)^2\) so that our above argument shows that \(|f(z) - \tau_k f(z)| \leq bc\). Moreover \((1+c)ab < 1\). Therefore Lemma 3 applies and yields the proposition.

We generalize the proposition slightly to the case of \(|z| < r\) rather than \(|z| < 1\).

**Corollary.** — Let \(f(z) = \sum a_j z^j\) be a one to one analytic function for \(|z| < r\) with \(a_0 = 0\), \(a_1 = 1\) and let \(g\) be its inverse. Then
\[ |g(f(z)) - g(\tau_k f(z))| \leq \frac{r \gamma^{k+1}(1-\gamma)^2 B(k+1)}{[(1-\gamma)^2 - 4\gamma][(1-\gamma)^2 - 4\gamma(1+B(k+1)\gamma^k)]},\]
for \(\gamma = |z|/r\) less than the first positive root of the denominator.

**Proof.** — The map \(z \to 1/r f(rz)\) is schlicht with inverse \(w \to (1/r)g(rw)\). Apply the Proposition to estimate
\[ \left| \frac{1}{r} g(f(z)) - \frac{1}{r} g(\tau_k f(z)) \right|.\]
Q.E.D.

Now we use the polynomial \(\sigma\) associated to \(f\) and \(z\) from section 1 together with the last Corollary to obtain Theorem 1. From Proposition 2 of section 1 and the discussion after it, one has
\[ \frac{f(z')}{f(z)} = 1 - \sigma \circ R, \quad R = \tau_k \sigma^{-1}(h).\]

Thus
\[ \frac{f(z')}{f(z)} = 1 - \sigma \tau_k \sigma^{-1}(h) = 1 - h - (\sigma \tau_k (\sigma^{-1} h) - \sigma (\sigma^{-1} h)).\]

Since \(\sigma^{-1}\) is an analytic function, one to one on a disc of radius \(h_1 = h_1(f, z)\) about 0, we can apply the preceding Corollary to obtain Theorem 1.

**Remark 1.** — If the Bieberbach conjecture is true, \(B=1\), see above and Duren. In any case, using results of Bieberbach, Loewner, Shiffer and others \(B\) can be replaced by something less than 1.07 and the 4's can be replaced by a smaller number.

**Remark 2.** — The case of Theorem 1 for \(k=1\), incremental Newton's method, was also studied in Smale. Unfortunately the theorem here doesn't imply that one.
The main applications of Theorem 1 are in sections 3 and 4. In the meantime we give a Corollary which for the classical case of $h=1$, gives new convergence criteria.

**Lemma 4.** $\beta'_k(\gamma)>0$ for $0<\gamma<\gamma_k$.

**Proof.** Use the quotient rule to differentiate $\beta_k(\gamma)$. Write the numerator as

$$2B(k+1)(1-\gamma)[(2+2\gamma)((1-\gamma)^2-4\gamma(1+B(k+1)\gamma^2))+(1-\gamma)((1-\gamma)^2-4\gamma)(1-\gamma)$$

$$+2(1+(k+1)B\gamma^2)+2B\gamma k(k+1)\gamma^{k-1}]$$

and all the terms are positive since $0<\gamma<\gamma_k$.

Note that $\gamma_k$ increases with $k$ and tends to the first root of $(1-\gamma)^2-4\gamma=0$ which is $3-\sqrt{8}=1.71572$.

Here we tabulate some values of $\gamma_k$ calculated to six decimal places by Gerry Roskes, who also did the other calculations in this paper with $B=1.07$.

We will see that Theorem 1 is interesting even for the case $h=1$.

In this case $z'=E_{h,k}(f,z)$, and

$$\frac{|f(z')|}{|f(z)|} \leq \beta_k(\gamma)\gamma^k \quad \text{where} \quad \gamma = \frac{1}{h},$$

$\gamma<\tilde{\gamma}_k$, where $\tilde{\gamma}_k$ is described as follows.

For $\gamma \in (0, \gamma_k)$ let $\alpha_k(\gamma) = \beta_k(\gamma)\gamma^k$. Then from Lemma 4 it follows that $\alpha_k(\gamma)$ is an increasing function of $\gamma$. Let $\tilde{\gamma}_k$ be the unique solution of $\alpha_k(\gamma)=1$. Clearly $\tilde{\gamma}_k$ increases with $k$ and tends to $3-\sqrt{8}$. One calculates to six decimals.

Define $\rho_f = \min_{\theta} |f(\theta)|$.

**Corollary 1.** Let $k>0$, and write for brevity $\bar{\gamma}=\tilde{\gamma}_k$. Suppose a polynomial $f$ and a complex number $z$ satisfy $|f(z)|=b(\bar{\gamma}/(1+\bar{\gamma}))\rho_f$ for some $b<1$. Then with $h=1$, $(E_{h<k})(z)=z_l$ is defined for all $l$ and $z_l \rightarrow z^*$ as $l \rightarrow \infty$ with $f(z^*)=0$. Moreover $|f(z_l)| \leq C|f(z_{l-1})|^{k+1}$ all $l>0$ (k+1 order convergence) with $C=(b/|f(z_0)|)^k$. Finally $|f(z_l)| \leq b^{(k+1)}(\bar{\gamma}/(1+\bar{\gamma}))\rho_f$, all $l>0$.
Proof. Let \( \gamma = \frac{|f(z)|}{|f(z) - f(\theta_*)|} \) where \( \rho_f = |f(\theta_*)|, f'(\theta_*)=0 \). Then \( \gamma < \gamma \) since
\[
|f(z) - f(\theta_*)| > \frac{1}{1 + \gamma} \rho_f
\]
and
\[
\frac{|f(z)|}{|f(z) - f(\theta_*)|} < \left( \frac{\gamma}{1 + \gamma} \rho_f \right) \left( \frac{1}{1/(1 + \gamma)} \rho_f \right) = \gamma.
\]
We may take \( h = 1 \) in Theorem 1. Thus
\[
\frac{|f(z')|}{f(z)} < \beta_k(\gamma) \gamma^k < \beta_k(\gamma) \gamma^k = 1,
\]
using Lemma 4 and the definition \( \gamma \) above. An obvious induction then yields the first part of Corollary 1.

Also
\[
\frac{|f(z')|}{f(z)} \leq \beta_k(\gamma) \frac{|f(z)|^k}{|f(z) - f(\theta_*)|} \leq C |f(z)|^k,
\]
where
\[
C = \beta_k(\gamma) \left( \frac{1 + \gamma}{\rho_f} \right)^k = \left( \frac{b}{|f(z)|} \right)^k.
\]
Next let \( y_0 = b \gamma \) and define inductively \( y_i = (y_{i-1})^{k+1} \beta_k(\gamma) \). Consider
\[
(1) \quad |f(z_l)| \leq y_l \frac{\rho_f}{1 + \gamma}, \quad l = 0, 1, 2, \ldots
\]
\[
(2) \quad y_l \leq y_{l-1}, \quad l = 0, 1, 2, \ldots
\]
where
\[
y_l = \min_{\theta : f' = 0} \frac{|f(z_l)|}{|f(z_l) - f(\theta)|}.
\]
Then \((1)_{\theta} \) is true by definition. We proceed inductively showing \((1)_{\theta} \) implies \((2)_{\theta} \) and then \((1)_{\theta-1} \) and \((2)_{\theta-1} \) imply \((1)_{\theta} \).

Thus
\[
y_l \leq \left( y_l \frac{\rho_f}{1 + \gamma} \right) \frac{1}{\min_{\theta} |f(z_l) - f(\theta)|} \leq y_{l-1} \frac{f(z_l)}{(1 + \gamma) \rho_f} \leq y_l.
\]
Finally

\[ |f(z_l)| \leq \beta_k(\gamma) \gamma_{i-1}^k |f(z_{i-1})| \leq \beta_k(\gamma) \gamma_{i-1}^k \left( \frac{\rho_f}{1 + \gamma} \right) \leq \gamma_i - \frac{\rho_f}{(1 + \gamma)}. \]

This proves (1.) and (2.) all \( l \).

One now checks inductively that \( y_t = b^{k+1} - \gamma \) and thus the statement of the Corollary.

Q.E.D.

Note the very rapid decrease of \( |f(z)| \) a function of \( l \). This justifies the following definition.

We will call \( z \) an approximate zero for \( f \) relative to \( k \) if and only if \( |f(z)| < \left[ \gamma_k/(1 + \gamma_k) \right] \rho_f \). An approximate zero for \( f \) relative to all \( k > 0 \) will be called simply an approximate zero so \( z \) is an approximate zero of \( f \) if and only if \( |f(z)| < \left[ \gamma_1/(1 + \gamma_1) \right] \rho_f \). Note by the computations below, if \( |f(z)| < \left( 1/12 \right) \rho_f \) then \( z \) is an approximate zero.

We tabulate some values of \( \gamma_k/(1 + \gamma_k) \). Note that \( \gamma_k/(1 + \gamma_k) \) is increasing and tends to \( (3 - \sqrt{8})/(1 + 3 - \sqrt{8}) = 0.146446 \) to six decimals.

<table>

</tbody>
</table>

So in particular \( 1/6 > \gamma_k/(1 + \gamma_k) > 1/12 \) and for \( k \geq 5, 1/6 > \gamma_k/(1 + \gamma_k) > 1/7 \).

We have applied Proposition 1 and its Corollary to \( \sigma \) and \( \sigma^{-1} \) to conclude Theorem 1. We could as well apply this reasoning to a general analytic function \( g \) defined on a domain \( \Omega \) and its inverse \( g^{-1} \). The resulting general statement is:

**Theorem 1 a.** — Let \( z \in \Omega \subseteq \mathbb{C} \) and let \( g : \Omega \to \mathbb{C} \) be analytic. Suppose \( g_x^{-1} \) is defined on a disc \( D \) of radius \( R(g, z) \). There are constants \( c_k \) and \( K_k \) depending on \( k \) (\( c_k \approx 1 \) and \( K_k \approx k \)) such that if \( |w - g(z)| < c_k R(g, z) \) and \( gg_x^{-1}(w) = w \) then

\[ |g((t_k g_x^{-1})^{-1}(w)) - w| \leq \frac{K_k |w - g(z)|^{k+1}}{R(g, z)^k}. \]

If we suppose that \( \rho_f > 0 \), then for any root \( \xi \) of \( f \), \( f'(\xi) \neq 0 \) and \( f_x^{-1} \) may be uniquely analytically continued along any ray starting from 0 as long as the inverse image of this ray doesn't run into a critical point of \( f \). Thus \( f_x^{-1} \) may be analytically continued to the entire complex plane minus \( k \) radial slits from \( f(\theta_1), \ldots, f(\theta_k) \) to \( \infty \) for some minimal collection \( \theta_1, \ldots, \theta_k \) of critical points of \( f \). We shall denote this domain by \( S_{\nu, f} \). For \( d > 1, 1 \leq k \leq d - 1 \). We use \( f_x^{-1} : S_{\nu, f} \to \mathbb{C} \) to denote the analytic
continuation. It is quite clear that the images of the $f_{\xi_i}^{-1}$ are disjoint over the roots $\xi_i$ of $f$ since the inverse image of a ray by $f_{\xi_i}^{-1}$ is a solution curve of the Newton differential equation $dz/dt = -f(z)/f'(z)$ in $\mathbb{R}^{2} = \mathbb{C}$ which terminates at $\xi_i$. Consider now a general $z \in \mathbb{C}$. If $f_{\xi}^{-1}$ can be analytically continued along the ray from $f(z)$ to 0 then $f_{\xi}^{-1} = f_{\xi_i}^{-1}$ in a neighborhood of this ray for some root $\xi$ of $f$. We analytically continue $f_{\xi}^{-1} : S_{\xi, f} \to \mathbb{C}$ by setting it equal to $f_{\xi_i}^{-1}$ and $S_{\xi, f} = S_{\xi_i, f}$.

We let $\rho_{f, \xi}$ be the radius of convergence of $f_{\xi}^{-1} : S_{\xi, f} \to \mathbb{C}$ around 0. Then $\rho_f = \min \rho_{f, \xi}$. We note that if $z' \in \text{Image } f_{\xi}^{-1} : S_{\xi, f} \to \mathbb{C}$ then $f_{\xi}^{-1} = f_{\xi_i}^{-1}$ and $S_{\xi, f} = S_{\xi_i, f}$.

The discussion above allows an improvement of the Corollary to Theorem 1, with the help of Proposition 4 below.

**COROLLARY 2.** — Corollary 1 to Theorem 1 remains true with $\rho_f$ replaced by $\rho_{f, \xi}$ and $z = f_{\xi}^{-1}(0)$ where $f_{\xi}^{-1} : S_{\xi, f} \to \mathbb{C}$.

Thus the notion of approximate zero may also be extended to $z$ satisfying $|f(z)| < \gamma(1 + \gamma)\rho_{f, \xi}$.

**PROPOSITION 2.** — Let $\xi_i, i = 1, \ldots, k$ be distinct simple roots of $f(z) = z^d + a_{d-1}z^{d-1} + \ldots + a_0$. Then the discs of radius

$$
\frac{1}{4} \frac{\gamma}{1 + \gamma} \frac{\rho_{f, \xi_i}}{|f'(\xi)|},
$$

centered at $\xi_i$ are disjoint and consist of approximate zeros.

For the proof of the Proposition we require a slight extension of the Bieberbach-Koebe Theorem.

**LEMMA 5.** — Let $f$ be a one to one analytic function defined on a disc of radius $r$, then the image of $f$ contains a disc of radius $|f'(0)|r/4$ around $f(0)$.

**Proof.** — $g(w) = (1/f'(0)r) f(rw) - f(0), |w| < 1$, is schlicht. So image $g$ contains a disc of radius $1/4$ around 0 and it follows that the image of $f$ contains a disc of radius $|f'(0)|r/4$ around $f(0)$.

**Proof of Proposition 2.** — By Lemma 5 the image by $f_{\xi_i}^{-1}$ of the disk of radius $[\gamma/(1 + \gamma)]\rho_{f, \xi_i}$ centered at 0 contains a disc of radius

$$
\frac{1}{4} \frac{\gamma}{1 + \gamma} \frac{\rho_{f, \xi_i}}{|(f_{\xi_i}^{-1})'(0)|} = \frac{1}{4} \frac{\gamma}{1 + \gamma} \frac{\rho_{f, \xi_i}}{|f'(\xi)|}.
$$

And these discs consist of approximate zeros.

It has already been noted that the images of the $f_{\xi_i}^{-1} : S_{\xi_i, f} \to \mathbb{C}$ are disjoint for distinct $\xi_i$.

**PROBLEM.** — Let $P_d(1) = \{ f | f(z) = z^d + a_{d-1}z^{d-1} + \ldots + a_0 \text{ with } |a_i| \leq 1 \}$. What is the distribution of

$$
\sum_{f(\xi) = 0} \left( \frac{\rho_{f, \xi}}{|f'(\xi)|} \right)^2 \text{ in } P_d(1)?
$$
We now give a simple estimate of the area of the set of approximate zeros of \( f \in P_d(1) \) which are contained in the unit disc.

**Lemma 6.** Suppose that \( p \) is a point in the unit disc on \( \mathbb{R}^2 \) and \( 0 < r < 1 \). Then the area of the intersection of the disk of radius \( r \) around \( p \) and the unit-disk is greater than

\[
\frac{r^2 \sqrt{4-r^2}}{2}.
\]

**Proof.** The worst case occurs for \( p \) on the boundary of the unit disk. Thus we may assume that \( p = (0, 1) \).

The x-coordinates of the points of intersections are \( \pm \left( r \sqrt{4-r^2} / 2 \right) \). Thus the area of the two triangles contained in the intersections is

\[
2 \left( \frac{r \sqrt{4-r^2}}{2} \right)^2 = \frac{r^2 \sqrt{4-r^2}}{2}.
\]

Q.E.D.

**Proposition 3.** Suppose that \( f \in P_d(1) \) and \( \rho_f > 0 \). Then the area of the set of points \( z \) in the unit disc such that \( f(z) < (\gamma/(1+\gamma)) \rho_f \) is at least

\[
.003 \left( \frac{\rho_f}{d(d+1)} \right)^2.
\]
Proof. — There is a root $\xi$ of $f$ in the closed unit disk since the product of the root is $\leq 1$.

$$|f'(\xi)| \leq d + (d-1) + \ldots + 1 = \frac{d(d+1)}{2}.$$  

Thus

$$\left| \frac{1}{f'(\xi)} \right| \geq \frac{2}{d(d+1)}.$$  

Now apply Lemma 5 to produce a disc centered at $\xi$, consisting of approximate zeros of $f$ and of radius

$$\frac{1}{2} \frac{1}{1+\gamma} \frac{1}{d(d+1)}.$$  

Use Lemma 6 to estimate the area, with the help of a hand held calculator. Since there is a critical point $\theta$ of $f$ in the unit disc $\rho_f \leq d+1$ which simplifies the expression in the radical.

It is convenient here to prove a Proposition which will be used in the proof of Theorem 2 and which can be used in the proof of Corollary 2. First we need a slight alteration of some estimates we have already used.

**Lemma 7.** — Let $f(z) = z + a_2 z^2 + \ldots$ be a $1-1$ analytic function defined in the disc of radius $h_\ast$. For $|z| < h_\ast$, let $\gamma = |z|/h_\ast$. Then

(a)  

$$|f(z)| \leq \frac{|z|}{(1-\gamma)^2},$$  

(b)  

$$|f(z) - \tau_k f(z)| \leq \frac{h_\ast B(k+1) \gamma^{k+1}}{(1-\gamma)^2}.$$  

Let $\sigma$ be the polynomial defined in section I and let $D(h_\ast)$ be the disc of radius $h_\ast$ around 0.

**Lemma 8.** — Suppose that $0 < h_\ast \leq h_1(f,z)$ and that $h = \gamma h_\ast$ for some $0 < \gamma < \gamma_k$. Then $\tau_k \sigma^{-1}(h) \in \sigma^{-1}(D(h_\ast))$.

**Proof.** — By Lemma 7 applied to $\sigma^{-1}$ on the disc of radius $h_\ast$

$$|\sigma^{-1}(h)| \leq \frac{h}{(1-\gamma)^2} \quad \text{and} \quad |\sigma^{-1}(h) - \tau_k \sigma^{-1}(h)| \leq \frac{h_\ast B(k+1) \gamma^{k+1}}{(1-\gamma)^2}.$$  

Thus

$$|\tau_k \sigma^{-1}(h)| \leq \frac{h}{(1-\gamma)^2} + \frac{h_\ast B(k+1) \gamma^{k+1}}{(1-\gamma)^2}.$$
By Lemma 5, $\sigma^{-1}(D(h_\ast))$ contains a disc of radius $h_\ast/4$ around 0. Thus $\tau_k\sigma^{-1}(h)\in\sigma^{-1}(D(h_\ast))$ as long as

$$\frac{h}{(1-\gamma)^2} + \frac{h_\ast B(k+1)\gamma^{k+1}}{(1-\gamma)^2} < \frac{h_\ast}{4},$$

or $(1-\gamma)^2 > 4\gamma(1+B(k+1)\gamma^{k+1})$. The first point of equality is the definition of $\gamma_k$.

**Proposition 4.** Suppose that $0<h_\ast \leq h_1(f, z)$ and that $h = \gamma h_\ast$ for some $0<\gamma<\gamma_k$. Let $z' = E_k(h_\ast, f)(z)$. Then there is a complex number $h'$ with $|h'| < h_\ast$ such that

$$z' = f^{-1}_z((1-h')f(z)),$$

where $f^{-1}_z : D(h_\ast) \to \mathbb{C}$.

**Proof.** We use the definition of $E_k$ and its relation to $\sigma^{-1}$ as discussed in section 1. $z' = z - F\tau_k(\sigma^{-1}(h))$. By Lemma 8, $\tau_k(\sigma^{-1}(h)) = \sigma^{-1}(h')$ with $|h'| < h_\ast$. Thus

$$z' = z + F\sigma^{-1}(h') = f^{-1}_z((1-h')f(z)),$$

by the discussion after the statement of Proposition 2 of section 1.

**Section 3**

Let $f$ be a polynomial $z$ a complex number. Then recall from section 1 that $f^{-1}_z$ is a function taking $f(z)$ to $z$, given by a power series on a disk of radius $r(f, z)$ about $f(z)$. Let us call that disk $D_f, z$, so $f^{-1}_z : D_f, z \to \mathbb{C}$ is analytic.

On the other hand one can consider other domains for $f^{-1}_z$. In particular define $W_{f, z}$ to be such a domain which is a wedge shaped circular sector as follows. For $0<\alpha \leq \pi/2$ let

$$W_{f, z, \alpha} = \left\{ w \in \mathbb{C} \mid 0 < |w| < 2|f(z)|, \left| \arg \frac{w}{f(z)} \right| < \alpha \right\}.$$ 

Then define $W_{f, z}$ to be the largest of the $W_{f, z, \alpha}$ on which $f^{-1}_z$ is analytic and let $\theta_{f, z}$ be the corresponding $\alpha$. Note that if $\theta_{f, z} < \pi/2$ then a critical value $f(\theta)$ lies on a side of $W_{f, z}$. It is clear that $W_{f, z} \subseteq S_{z, f}$ which was defined in section 2, and that $W_{f, z}$ is the largest $W_{f, z, \alpha}$ contained in $S_{z, f}$.

Our algorithms attempt to make this analytic continuation a computationally feasible process. What we do in this section is to show that the Euler algorithms yield a sequence of iterates $z_n$ whose values $f(z_n)$ remain in an appropriate wedge-shaped region $W_{f, z}$. 

**Annales Scientifiques de l'École Normale Supérieure**
Let
\[
K(k) = \frac{(k+1)^{k+1/k}}{K(\gamma_k) (1-\gamma_k)^{1/k}},
\]
where \(\gamma_k\) is the constant given in section 2.

**Theorem 2.** Suppose given a polynomial \(f\) and complex number \(z_0\) and a real number \(L > 0\) such that \(|f(z_0)| > L\) and \(\Theta = \theta_f, z_0 > 0\). Let \(c = 1/\Theta \log |f(z_0)|/L\). Then there is
\[
h_0 \geq \frac{\sin \Theta}{K(k) (c+1)^{1/k}}
\]
with this property: For each \(h, 0 < h \leq h_0\), there is some
\[
n \leq \left\lfloor \frac{1}{h} \left( \log \frac{|f(z_0)|}{L} + \frac{\Theta}{k+1} \right) \right\rfloor
\]
such that \(|f(z_n)| < L\) where \(z_n = E_k(\Theta, f)(z_0)\).

**Remark.** We actually prove a stronger statement. If \(a = k/(k+1)\sin \Theta\), one can take
\[
n = \left\lfloor \frac{1}{h} \log \frac{|f(z_0)|}{L} \left( \frac{1}{1-\alpha_k(h/a)} \right) \right\rfloor
\]
in the theorem where \([\gamma]\) denotes the smallest integer greater than or equal to \(x\). See Lemma 1 below. We also are using the functions \(\alpha_k(\gamma)\) introduced in section 2, which are defined and increasing in the range \(0 < \gamma < \gamma_k\).

**Note that** \(n\), the number of steps depends crucially on the constant (function of \(k\) only) \(K(k)\).
Here we tabulate some values of $K(k)$ to six decimal places. $K(k)$ decreases to $1/(3 - \sqrt{8}) = 5.82842$.

Note that for $k = 1$ or Newton’s method the value of $K(1)$ shows that Theorem 2 in that case is significantly worse than the results achieved in Smale.

**Corollary to Theorem 2.** — In addition to the hypotheses of Theorem 2, suppose that $L < (\gamma_1/(1 + \gamma_1)) \rho_f$. Then for all $0 < h \leq h_0$ in Theorem 2 and all

$$n \geq \frac{1}{h} \left( \log \frac{|f'(z_0)|}{L} + \Theta_{k+1} \right), \quad |f'(z_0)| < L.$$  

This is simply a consequence of Theorem 2 and the proof of Corollary 1, of Theorem 1.

The proof of Theorem 2 uses heavily Theorem 1 and partially generalizes Theorem 3 of Smale (the case $k = 1$, or Newton’s method).

**Lemma 1.** — For any $c > 0$, $0 < a < 1$, and $\alpha_k(\gamma)$ as above, there is a unique solution $h = h_0$ of $(k + 1)c + 1 = \frac{1 - h}{\alpha_k(h/a)}$ in the range $0 < h_0 < a \gamma_k$.

This $h_0$ satisfies

$$h_0 \geq \frac{a(k + 1)}{k K(k)(c + 1)^{1/k}}.$$  

Furthermore for $0 < h \leq h_0$,

$$\frac{1}{1 - \alpha_k(h/a)} \leq 1 + \frac{1}{c(k + 1)}.$$  

**Proof.** — The right hand of the equation for $h_0$ decreases monotonically from $\infty$ to below 1 as $h$ goes from 0 to $a \gamma_k$ (Lemma 4 of section 2). Since $(k + 1)c + 1 > 1$, this yields the unique solution $h_0$.

Since $\alpha_k(h/a) \leq \alpha_k(h_0/a)$ for $h < h_0$, using the defining equation for $h_0$ we have

$$\frac{1}{1 - \alpha_k(h/a)} \leq \frac{(k + 1)c + 1}{(k + 1)c + h_0} \leq 1 + \frac{1}{c(k + 1)}.$$  

**Annales Scientifiques de l’École Normale Supérieure**
This gives the last statement of Lemma 1. It remains to show
\[ h_0 \geq \frac{a(k+1)}{k K (k) (c+1)^{1/k}}. \]

Note \( h_0 \leq a \gamma_k < \gamma_k \) since \( a < 1 \). Then use the defining equation for \( h_0 \) to obtain
\[ \alpha_k \left( \frac{h_0}{a} \right) = \frac{1-h_0}{k (c+1)+1} \geq \frac{1-\gamma_k}{k (c+1)+1}. \]

From the definition \( \alpha_k(\gamma) = \beta_k(\gamma) \gamma^k \) of section 2, we have
\[ \left( \frac{h_0}{a} \right)^k \beta_k \left( \frac{h_0}{a} \right) = \alpha_k \left( \frac{h_0}{a} \right) \geq \frac{1-\gamma_k}{k (c+1)+1}, \]
so
\[ \left( \frac{h_0}{a} \right)^k \geq \frac{1-\gamma}{(k (c+1)+1)} \geq \frac{1-\gamma_k}{(k (c+1)+1)} \frac{1}{\beta_k(\gamma_k)} \frac{1}{(k (c+1)+1)} = \frac{1-\gamma_k}{\gamma_k^{k}}. \]

By taking \( k \)-th roots,
\[ \frac{h_0}{a} \geq \frac{\gamma_k (1-\gamma_k)^{1/k}}{(k (c+1)+1)^{1/k}} \geq \frac{\gamma_k (1-\gamma_k)^{1/k}}{(k+1)^{1/k} (c+1)^{1/k}} \geq \frac{1}{K(k)} \frac{k+1}{k} \frac{1}{(c+1)^{1/k}} \]
and thus our desired inequality.

Q.E.D.

The last part of Lemma 1 explains the remark after Proposition 2 since by it,
\[ \frac{1}{h} \log \frac{|f(z_0)|}{L} \left( \frac{1}{1-\alpha_k(h/a)} \right) \leq \frac{1}{h} \left( \log \frac{|f(z_0)|}{L} + \frac{\Theta}{k+1} \right). \]

In fact we proceed to prove Theorem 2 in the form of the \( n \) in this remark.

**Lemma 2.** \( h_1(f, z) \geq \sin \theta_f, \ z \)

**Proof.** If \( \theta_f, z = \pi/2 \) then the wedge is a semi-circle of
radius $2|f(z)|$ and the circle of radius $|f(z)|$ about $f(z)$ is contained in the wedge. Thus
\[ h_1(f, z) \equiv \frac{|f(z)|}{|f(z)|} = 1 = \sin \frac{\pi}{2}. \]

If $\theta_{f, z} < \pi/2$, fix a critical point $\theta$ which maps to the boundary of the wedge.

\[ \theta_{f, z} \]

Then $h_1(f, z) = |f(z) - f(\theta)| / |f(z)| \geq \sin \theta_{f, z_0}$.

Q.E.D.

From trigonometry, one has:

**Lemma 3.** — For $0 \leq x < \pi/2$, $0 \leq \alpha \leq 1$,

(a) $|\arctan(x)| \leq x$ and

(b) $\sin \alpha x \geq \alpha \sin x$.

The next step is to use Theorem 1, section 2. We write

\[ \gamma = \frac{h}{h_1}; \quad 0 < \gamma \leq \gamma_k, \quad \beta_k(\gamma) \gamma^k = \alpha_k(\gamma) \leq \alpha_0(\gamma_k) = 1. \]

Then Theorem 1 asserts

\[ \frac{f(z')}{f(z)} = 1 - h + Q(h, f, z) \gamma^k h \]

\[ = 1 - (1 - Q(h, f, z) \gamma^k) h, \]

where $|Q(h, f, z)| \leq \beta_k(\gamma)$.

Already this yields the first part of the following lemma.

**Lemma 4.** — Let $z' = E_k(h, f, z)$ where $E_k$ is the $k$-th order Euler incremental algorithm. Then with the above notation for $0 < \gamma < \gamma_k$

(a) $\frac{|f(z')|}{|f(z)|} \leq 1 - (1 - \alpha_k(\gamma)) h,$

(b) $\left| \arg \frac{f(z')}{f(z)} \right| < \frac{\alpha_k(\gamma) h}{1 - (1 + \alpha_k(\gamma)) h}.$
The proof of (b) goes by the consequence of Theorem 1 above and is aided by the diagram.

\[ \frac{f(z')}{f(z)} \]

\[ \left| \frac{\text{im} Q(h, f, z) \cdot h^{k+1}}{h_k} \right| \]

\[ |1 - h + \text{Re} Q(h, f, z) \cdot h^{k+1}|, \]

\[ \left| \frac{\text{arg} \frac{f(z')}{f(z)}}{1 - h + \text{Re} Q(h, f, z) \cdot h^{k+1}} \right| = \text{arc tan} \left( \frac{\text{im} Q(h, f, z) \cdot h^{k+1}}{1 - h + \text{Re} Q(h, f, z) \cdot h^{k+1}} \right) \]

\[ \frac{\beta_k(\gamma) \gamma^k h}{1 - h - \beta_k(\gamma) \gamma^k h} = \frac{\alpha_k(\gamma) h}{1 - h - \alpha_k(\gamma) h}. \]

We have used Lemma 3; this proves Lemma 4.

Let

\[ a = \frac{k}{k + 1} \sin \theta_{f, z_0} \quad \text{and} \quad \delta = \frac{h}{a}. \]

**Lemma 5.** — Let \( 0 < \delta < \gamma_k \) and \( z_n = E_{k+1}(h, f, z_0) \). Then for

\[ 0 \leq n \leq \frac{(1 - (1 + \alpha_k(\delta) h))}{(k + 1) \alpha_k(\delta) h} \theta_{f, z_0}, \]

we have

\[ \theta_{f, z_n} \geq \frac{k}{k + 1} \theta_{f, z_0} \quad \text{and} \quad \frac{f(z_{n+1})}{f(z_0)} \leq (1 - (1 - \alpha_k(\delta) h)^{n+1} |f(z_0)|. \]

The proof goes by induction on \( n \), the case \( n = 0 \) given by Lemma 4 a.

First note that if \( \theta_{f, z_n} \geq \frac{k}{k + 1} \theta_{f, z_0} \) then by Lemmas 2 and 3 b,

\[ h_1(f, z_n) \geq \sin \frac{k}{k + 1} \theta_{f, z_0} \geq \frac{k}{k + 1} \sin \theta_{f, z_0} \quad \text{so} \quad \gamma = \frac{h}{h_1(f, z_n)} < \delta. \]

and

\[ \left| \frac{\text{arg} \frac{f(z_{n+1})}{f(z_n)}}{1 - (1 + \alpha_k(\gamma)) h} \right| \leq \frac{\alpha_k(\gamma) h}{1 - (1 + \alpha_k(\gamma)) h} < \frac{\alpha_k(\delta) h}{1 - (1 + \alpha_k(\delta)) h}. \]
and
\[ \left| \frac{f(z_{n+1})}{f(z_n)} \right| \leq 1 - (1 - \alpha_k(\gamma)) h < 1 - (1 - \alpha_k(\delta)) h. \]

Using Lemma 4 applied to \( z_n \) instead of \( z \). If \( \theta_{f, z_n} \geq k/(k+1) \theta_{f, z_0} \) then it is also true that

\[ \theta_{f, z_{n+1}} \geq \theta_{f, z_n} - \left| \arg \frac{f(z_{n+1})}{f(z_n)} \right|, \]

for: By Proposition 4 of section 2 with \( h_\bullet = k/(k+1) \sin \theta_{f, z_0} \) there is a complex number \( h' \) with \( |h'| < h_\bullet \) such that

\[ z_{n+1} = f_{z_n}^{-1}((1-h')f(z)). \]

Thus \((1-h')f(z) \in W_{f, z_n} \) and \( z_{n+1} \in \text{Image} f_{z_n}^{-1} \) where \( f_{z_n}^{-1} : S_{z_n, f} \to \mathbb{C} \). It follows from the discussion of \( S_{z, f} \) in section 2 and following the definition of \( \theta_{f, z} \) in section 3, that \( S_{z_n, f} = S_{z_{n+1}, f} \). It is then immediate from the definition of \( \theta_{f, z} \) that

\[ \theta_{f, z_{n+1}} > \theta_{f, z_n} - \left| \arg \frac{f(z_{n+1})}{f(z_n)} \right|. \]

Thus we may proceed by induction as long as we are sure that

\[ \theta_{f, z_n} \geq \frac{k}{k+1} \theta_{f, z_0} \]

or as long as

\[ \theta_{f, z_0} - \frac{n \alpha_k(\delta) h}{1 - (1 + \alpha_k(\delta)) h} \geq \frac{k}{k+1} \theta_{f, z_0}, \]

that is: as long as

\[ 0 \leq n \leq \frac{1 - (1 + \alpha_k(\delta)) h}{(k+1) \alpha_k(\delta) h} \theta_{f, z_0}. \]

With these lemmas done, we are now prepared to give the proof of Theorem 2, \( n \) as in the remark following that theorem.

Use Lemma 1 with

\[ a = \frac{k}{k+1} \sin \Theta \quad \text{and} \quad c = \frac{1}{\Theta} \log \frac{|f(z_0)|}{L}, \]
to obtain $h_0$ of Theorem 2. This $h_0$ will thus satisfy the inequality of Theorem 2. Now we have to show that for $0 < h \leq h_0$ and

$$n = \left\lceil \frac{1}{h} \log \left( \frac{|f(z_0)|}{L} \frac{1}{1 - \alpha_k(h/a)} \right) \right\rceil$$

then $|f(z_0)| < L$.

We need to apply Lemma 5 [with $(n-1)$ replacing $n$] to obtain

$$|f(z_0)| \leq (1 - (1 - \alpha_k(\delta))h)^n |f(z_0)| \leq L.$$  
For this it is required that

$$n \log (1 - (1 - \alpha_k(\delta))h) \leq \log \left( \frac{L}{|f(z_0)|} \right),$$

or

$$n \geq \frac{\log \left( \frac{|f(z_0)|}{L} \right)}{\log (1 - (1 - \alpha_k(\delta))h)}$$

and

$$(A) \quad n \geq \frac{\log \left( \frac{|f(z_0)|}{L} \right)}{(1 - \alpha_k(\delta))h}$$
suffices.

On the other hand Lemma 5 demands an upper bound on $n - 1$, namely

$$(B) \quad \frac{1 - (1 + \alpha_k(\delta))h}{(k + 1) \alpha_k(\delta)h} \geq n - 1.$$  

Thus if $\delta, h (\delta = h/a)$ satisfy

$$(C) \quad \frac{1 - (1 + \alpha_k(\delta))h}{(k + 1) \alpha_k(\delta)h} \geq \frac{\log \left( \frac{|f(z_0)|}{L} \right)}{(1 - \alpha_k(\delta))h},$$

then there is an integer $n$ which satisfies both $(A)$ and $(B)$. We now find $\delta$'s which make $(C)$ hold, or

$$\frac{1 - (1 + \alpha_k(\delta))h}{(k + 1) \alpha_k(\delta)} \geq \frac{\log \left( \frac{|f(z_0)|}{L} \right)}{\theta_{f, z_0} (1 - \alpha_k(\delta))} = \frac{c}{1 - \alpha_k(\delta)}.$$  

Now multiplying by $1 - \alpha_k(\delta)$ and $k + 1$ it suffices to have

$$\frac{(1 - \alpha_k(\delta))(1 - (1 + \alpha_k(\delta))h}{\alpha_k(\delta)} \geq (k + 1)c.$$  

$$\frac{(1 - h - \alpha_k(\delta)h + \alpha_k h + \alpha_k(\delta)h^2)}{\alpha_k(\delta)} \geq (k + 1)c.$$
So it suffices to have
\[ \frac{1 - h}{\alpha_k(\delta)} - 1 \geq (k + 1)c \quad \text{or} \quad \frac{1 - h}{\alpha_k(\delta)} \geq (k + 1)c + 1. \]

But this last exactly corresponds to our defining equation (Lemma 1) for \( h_0 \), so that \( h \leq h_0 \) guarantees the inequality is satisfied. This finishes the proof of Theorem 2.

Section 4

The Corollary of Theorem 2 shows that the crucial ingredients for producing an approximate zero for \( f \), starting at \( z_0 \) and iterating \( E_{\lambda(h, f)} \), are
\[ \theta_{f, z_0} \log |f(z_0)| \quad \text{and} \quad |\log \rho_f|. \]
In this section we tend to increase \( \theta_{f, z_0} \) at the expense of increasing \( |f(z_0)| \). Doing so we gain considerably. In particular, we prove in this section:

**Theorem 3.** There exist universal (small) positive constants \( K_1, K_2 \) with the following true. Given integers \( k > 0 \), and \( d > 1 \), and a real number \( 1 > \mu > 0 \) : There are \( R, h \) such that:

If \((z_0, f) \in S_R \times P_d(1)\) then \( z_s = ((E_{\lambda(h, f)})^\gamma(z_0)) \)

will be an approximate zero of \( f \), with probability \( 1 - \mu \) for any
\[ s \geq K_1 \left( d \frac{\log \mu}{\mu} \right)^{1 + 1/k} + K_2. \]

Here \( S_R = \{ z \in \mathbb{C} \| z \| = R \} \), \( P_d(1) \) is the space of all complex polynomials
\[ f(z) = \sum_{i=1}^{d} a_i z^i \quad \text{with} \quad a_d = 1 \quad \text{and} \quad |a_i| \leq 1 \quad \text{for} \quad i = 1, 2, \ldots, d - 1 \]
and \( \mu \) is normalized Lebesque measure on the product \( S_R \times P_d(1) \).

**Corollary.** Given \( d > 1 \), \( 1 > \mu > 0 \) there are \( R, h \) such that:

If \((z_0, f) \in S_R^1 \times P_d(1)\) then \( z_s = E_{\lambda d}^\lambda(z_0) \) is an approximate zero of \( f \) with probability \( 1 - \mu \) for any
\[ s \geq \epsilon K_1 d \left( \frac{\log \mu}{\mu} \right)^{1 + 1/\log d} + K_2. \]

**Proof.** Let \( k \) the smallest integer greater than \( \log d \) in Theorem 4, then \( d^{(k + 1)/k} \leq \epsilon d \).

If the constants \( K_1, K_2 \) in Theorem 3 and its corollary were allowed to depend on \( k \), \( K_1 \) would be approximately \( K(k) \) of section 3 and \( K_2 \) even smaller. Recall that \( K(k) \) decreases rapidly with \( k \) to about 7. One obviously can construct an appropriate algorithm for Theorem 3 and its Corollary.

Annales Scientifiques de l'École Normale Supérieure
To prove Theorem 3 we want to estimate the normalized Lebesgue measure of the set in $S_R \times P_d(1)$ where $\rho_f$ is small or $\theta_f, z_0$ is small.

$$Y_{u, a, R} = \{(z_0, f) \in S_R^1 \times P_d(1) \mid \rho_f < a \text{ or } \theta_f, z_0 < \sigma\}.$$

PROPOSITION 1. — For $R > 2$, $\sigma < \pi/2$,

$$\mu(Y_{u, a, R}) \leq (d-1)\alpha^2 + \frac{2}{\pi} \left(\frac{d-1}{d}\right) \left(\sigma + 2 \arcsin \frac{1}{R-1}\right).$$

First we prove Theorem 3 from the Proposition.

Besides $k$, and $d$ we are given $\mu$, $0 < \mu < 1$. The following equations are easily solved for $\alpha$, $R$, and $\sigma$.

$$(d-1)\alpha^2 = \frac{\mu}{10},$$

$$\frac{4}{\pi} \left(\frac{d-1}{d}\right) \arcsin \frac{1}{R-1} = \frac{\mu}{10},$$

$$\frac{2}{\pi} \left|\frac{d-1}{d}\right| \sigma = \frac{4\mu}{5},$$

In fact

$$\alpha = \left(\frac{\mu}{10} \left(\frac{1}{d-1}\right)\right)^{1/2},$$

$$R = \left[\sin \left(\frac{\mu \pi}{40} \left(\frac{d}{d-1}\right)\right)\right]^{-1} + 1,$$

$$\sigma = \frac{2\pi\mu}{5} \left(\frac{d}{d-1}\right).$$

From Proposition 1 it follows that $\mu(Y_{u, a, R}) < \mu$ i.e. the measure of $Y_{u, a, R}$ is less than the given $\mu$ using the probability measure on $S_R^1 \times P_d(1)$. Thus $(z_o, f)$ in $S_R^1 \times P_d(1)$ is not in $Y_{u, a, R}$ with probability $1 - \mu$. For such $z_0, f$, $\rho_f > \alpha$ and $\theta_f, z_0 > \sigma$.

We apply the Corollary of Theorem 2 to obtain an approximate zero of $f$.

To find the $K_1, K_2$ and estimates of Theorem 3, one calculates those quantities from that Corollary. We don't carry out the straightforward calculation here, but indicate how it goes. In the Corollary (Theorem 2) the number of steps $s$ (denoted by $n$ in the corollary) is given as a function of $|f(z_0)|$, $\theta$, and $\rho_f$ (instead of $L$); keep $k$ fixed throughout.

But $s$ in Theorem 3 is given as a function of $d$ and $\mu$. Thus it is required to see how $d$ and $\mu$ depend on $|f(z_0)|$, and $\rho_f$. This goes as follows.
From the construction of $Y_a, \sigma, R$ we may replace $\theta$ by $\sigma$ and $\rho_f$ by $\alpha$. Moreover since
\[
|f(z_0)| = \left| \sum_{i=0}^{d} a_i z_0^i \right| \leq \sum_{i=0}^{d} R^i = \frac{R^{d+1} - 1}{R - 1},
\]
we may replace $|f(z_0)|$ by $(R^{d+1} - 1)/(R - 1)$. These remarks yield the number of steps given by the Corollary as a function now of $\sigma, \alpha,$ and $R$. By substituting the values of $\sigma, \alpha,$ and $R$ given by the above equations, yields $s$ in terms of $\mu$ and $d$. This function $s$ of $\mu$ and $d$ simplifies to give Theorem 3.

It remains to prove Proposition 1. We have

**Proposition 2.** (Smale)

\[
\text{Vol} \{ f \in \mathbb{P}_d(1) \mid \rho_f < \alpha \} \leq (d - 1) \alpha^2
\]

Where Vol means normalized Lebesgue measure in $\mathbb{P}_d(1)$. [Actually Smale writes $da^2$ but the proof gives $(d - 1) \alpha^2$.]

Thus the remaining work of this section is to prove:

**Proposition 3.** For $\alpha < \pi/2, f \in \mathbb{P}_d(1), R > 2,$
\[
\text{Vol} \{ z_0 \in S^d_R \mid \theta_{f, z_0} < \alpha \} \geq \frac{2}{\pi} \left( \frac{d-1}{d} \right) \left( \alpha + 2 \arcsin \left( \frac{1}{R-1} \right) \right).
\]

In fact, $\{ z_0 \in S^d_R \mid \theta_{f, z_0} < \alpha \}$ is contained in at most $2(d-1)$ arcs of $S^d_R$ of angle $2/\left[ \alpha + 2 \arcsin \left( 1/(R-1) \right) \right]$.

Here Vol again is normalized Lebesgue measure so that $V(S^d_R) = 1$. Note that Proposition 1 follows at once from Propositions 2 and 3.

The following lemma is essentially the Gauss-Lucas Theorem, see Henrici. Recall that for two complex numbers $z, w$, $\text{Re}(zw)$ is the usual inner product of $z$ and $w$ as vectors in $\mathbb{R}^2$.

**Lemma 1.** Let $f = z^d + a_{d-1} z^{d-1} + \ldots + a_0$ be a complex polynomial and let $S^d_R$ contain all the roots of $f$ in its interior. Then for any $z \in S^d_R$
\[
\text{Re} \left( \frac{f(z)}{f'(z)} \right) > 0.
\]

Moreover the Newton differential equation $dz/dt = -f(z)/f'(z)$ is transversal to $S^d_R$ and points inward.

**Proof.** Let $w_1, \ldots, w_n$ be the roots of $f$. Then the $w_i$ are in the half plane defined by the tangent space to the circle at $z$, i.e. $\text{Re}(\overline{z}w_i) < \overline{z}z$.

It follows that
\[
\text{Re}(\overline{z}(z-w_i)) > 0,
\]
\[
\text{Re} \left( \frac{z}{z-w_i} \right) > 0,
\]
\[
\text{Re} \left( \frac{z^2-zw_i}{z-w_i} \right) > 0.
\]
For the last part if \( z \in S_k^1 \), then the inner product
\[
\left( z, \frac{-f(z)}{f'(z)} \right) = \Re \left( \frac{-\bar{z}f(z)}{f'(z)} \right) < 0.
\]

**Lemma 2.** Suppose \( f \in P_d(1), R \geq 2 \). Let \( z_1, z_2 \in S_k^1 \) such that
\[
\left| \frac{z_1}{z_2} \right| < \beta < \frac{\pi}{d}.
\]
Then
\[
d\beta + 2 \arcsin \frac{1}{R-1} \geq \left\| \frac{f(z_1)}{f(z_2)} \right\| \geq d\beta - 2 \arcsin \frac{1}{R-1}.
\]

**Proof.**
\[
\frac{f(z)}{z^d} = 1 + \frac{a_d-1 z^{d-1}}{z^d} + \ldots + a_0
\]
and for \( z \in S_k^1 \)
\[
\left| \sum_{j=0}^{d-1} a_j z^j \right| \leq \sum_{j=0}^{d-1} \frac{R^j}{R^d} = \frac{R^{d-1}-1}{R-1} < 1.
\]
Thus \( f(z)/z^d \) is inside the circle of radius \( 1/(R-1) \) centered by 1, and
\[
\left| \frac{f(z)}{z^d} \right| \leq \arcsin \frac{1}{R-1}.
\]

Now
\[
\frac{f(z_1)}{f(z_2)} = \frac{z_2^d (f(z_1)/z_1^d)}{z_1^d (f(z_2)/z_2^d)} = \left( \frac{z_1}{z_2} \right)^d \frac{f(z_1)/z_1^d}{f(z_2)/z_2^d}
\]
and the lemma follows from the fact that the argument of a product is additive and the triangle inequality.

Let \( \theta \) be a critical point of \( f \). Let \( L \) be the ray through \( f(\theta) \), \( L = \{ \lambda f(\theta) \mid \lambda > 0 \} \) and \( \Sigma_\theta \) the component of \( f^{-1}(L) \) which contains \( \theta \). Let \( \sum_{\theta} = \bigcup_{\theta} \sum_\theta \).

\[ \text{Lemma 3. } \text{If } R \geq 2, f \in P_d(1) \text{ then } \sum_{\theta} \cap S_\theta \text{ is a set of at most } 2(d-1) \text{ points.} \]

\[ \text{Proof. } \text{Recall from section one that the inverse images of rays by } f \text{ are solution curves of the differential equation } \frac{dz}{dt} = (f'(z))/f''(z) \text{ which by Lemma 1 are transversal to } S_\theta \text{ for any } R \geq 2. \text{ It follows that for any fixed } \theta_i \text{ such that } f'(\theta_i) = 0, \sum_{\theta_i} \cap S_\theta \text{ consists of at most } k_i + 1 \text{ points where } k_i \text{ is the multiplicity of } \theta_i \text{ as a root of } f'. \text{ Thus}
\]
\[
\sum_{\theta_i} k_i = d-1 \quad \text{and} \quad \sum_{\theta_i} (k_i + 1) \leq 2(d-1).
\]

Equality is only obtained here if each critical point \( \theta_i \) is a simple zero of \( f' \), i.e., if each \( k_i = 1 \).

Consider now the map \( f_\xi^{-1} : S_\xi \to C \) for \( \xi \) a root of \( f \) (see section 2). Recall that \( S_\xi \) for \( \xi \in C - Q \) where \( Q \) consists of parts of certain rays. Now given an angle \( \alpha \), let \( U_{\xi, \alpha} \) be the set of all numbers \( w \) in \( S_\xi \) such that \( \arg \frac{w}{q} < \alpha \), some \( q \in Q \). It follows that:

\[ \text{Lemma 4. } \text{Let } \alpha < \pi/2. \text{ If } z \text{ is not in any } f_\xi^{-1}(U_{\xi, \alpha}) \text{ for any } \xi \text{ with } f(\xi) = 0, \text{ then } \theta_{f, z} > \alpha. \]

Moreover:

\[ \text{Lemma 5. } \text{Let } \alpha < \pi/2, \text{ and}
\]
\[
N(\alpha) = S_\theta \cap \bigcup_{\xi} f_\xi^{-1}(U_{\xi, \alpha}).
\]

Then
\[
\text{Vol } N(\alpha) \leq \frac{2(d-1)}{\pi d} \left( \alpha + 2 \arcsin \frac{1}{R-1} \right).
\]

Here \( \text{Vol} \) refers to normalized Lebesgue measure in \( S_\theta \).

\[ \text{Proof. } \text{Keep in mind that the } f_\xi^{-1} \text{ have disjoint images. Using Lemma 3 it follows that } N(\alpha) \text{ is contained in the set of at most } 2(d-1) \text{ intervals } N(\alpha, z_0), z_0 \in \sum_{\theta} \cap S_\theta, \text{ about the } 2(d-1) \text{ points of } \Sigma \cap S_\theta. \text{ The problem is to estimate the measure of these intervals. This is accomplished as follows. If } z \in N(\alpha, z_0), \text{ then } \left| \arg \frac{f(z)}{f(z_0)} \right| < \alpha. \text{ By Lemma 2,}
\]
\[
\left| \arg \frac{z}{z_0} \right| d - \alpha \leq 2 \arcsin \frac{1}{R-1} \text{ so } \left| \arg \frac{z}{z_0} \right| \leq \frac{1}{d} \left( \alpha + 2 \arcsin \frac{1}{R-1} \right).
\]
Since there are two sides of $z_0$ in $N(\alpha, z_0)$ the total angle of $N(\alpha)$ is bounded by $4(d-1)/d[\alpha+2 \arcsin 1/(R-1)]$. Dividing by $2\pi$ yields Lemma 5. With Lemma 4 that gives us Proposition 3.

**Section 5**

The goal of this section is to extend Theorem 2 to any incremental algorithm of efficiency $k$. Since the proof is similar to the proof of Theorem 2, we are brief.

Let

$$\Lambda_{f, z_0} = \min_{\theta, \alpha} \left| \arg \frac{f(z_0)}{f(\theta)} \right|.$$  

**Theorem 4.** — Suppose that an incremental algorithm $I$ has efficiency $k$. Then there is a constant $K$ depending only on $I$ such that:

If $\Lambda_{f, z_0}>0$ and $|f(z_0)| > L > 0$, then there is an $h$ given explicitly such that $|f(z_n)| < L$ for

$$n = K \left[ \log \left| \frac{f(z_0)}{|L|} \right| \Lambda_{f, z_0} + 1 \right]^{1+1/k},$$

where $z_n = (I^n_{h, f})^n(z_0)$.

$\Lambda_{f, z_0}$ coincides with $\theta_{f, z_0}$ in Smale but not with the $\theta_{f, z_0}$ we have used above. For our $\theta_{f, z_0}, \Lambda_{f, z_0} \leq \theta_{f, z_0} [x]$ means the smallest integer greater than or equal to $x$. We take less care about the constants here than in the proof of Theorem 2, although some estimate is given at the end of the proof of the theorem. Recall that $I_{h, f}$ is of efficiency $k$ provided that there exist real constants $\delta > 0$, $K > 0$, $c_1, \ldots, c_k > 0$ independent of $h, f$ and $z$ such that

$$\frac{f(I_{h, f}(z))}{f(z)} = 1 - (c_1 h + \ldots + c_k h^k) + S_{k+1}(h)$$

where

$$|S_{k+1}(h)| \leq K h^{k+1} \max\left(1, \frac{1}{h_1^k}\right)$$

for $0 < h < \delta \min(1, h_1)$.

**Lemma 1.** — There is a constant $a$, $1 \geq a \geq 0$, depending only on $I$ such that:

If $0 < h < a \min(1, h_1)$ then

$$\left| \frac{f(z)}{f(z)} \right| < 1 - \frac{c_1 h}{2} \quad \text{and} \quad \left| \arg \frac{f(z)}{f(z)} \right| < 2 K h^{k+1} \max\left(1, \frac{1}{h_1^k}\right)$$
Proof. Let 
\[ a = \min \left( 1, \delta, \frac{1}{3c_1}, \frac{c_1}{k}, \left( \frac{c_1}{4K} \right)^{1/k} \right) . \]

Then 
\[ f(z)f(z') = 1 - c_1 h - \sum_{i=2}^{k} c_i h^i + S_{k+1}(h) \] where \( h < a \min (1, h_1) \)

\[ \left| \sum_{i=2}^{k} c_i h^i \right| \leq h^2 \sum_{i=2}^{k} |c_i| < ha \sum_{i=2}^{k} |c_i| \leq h \frac{c_1}{4}, \]

\[ |S_{k+1}(h)| \leq h K \max \left( h_{k+1} \left( \frac{h}{h_1} \right)^k \right) \leq h K a^k < h \frac{c_1}{4}. \]

Thus
\[ \frac{f(z')}{f(z)} = 1 - c_1 h + \alpha \text{ where } |\alpha| < \frac{hc_1}{2} \text{ and } |\text{im } \alpha| \leq |S_{k+1}(h)|. \]

So
\[ \left| \frac{f(z')}{f(z)} \right| \leq 1 - \frac{c_1 h}{2}. \]

Since
\[ \frac{3}{2} c_1 h < \frac{3}{2} c_1 a \leq \frac{1}{2}, \quad 0 < 1 - \frac{3}{2} c_1 h < \text{re} f(z') \frac{f(z')}{f(z)}. \]

Now
\[ \left| \frac{\arg f(z')}{f(z)} \right| = \arctan \left( \frac{|\text{im } \alpha|}{\text{re} \left( f(z')/f(z) \right)} \right). \]
and by Lemma 3 of section 3

\[ \left| \text{arg} \frac{f(z')}{f(z)} \right| \leq \left| \frac{\lim \alpha}{\text{re}(f(z')/f(z))} \right| \leq \frac{h^{k+1} K \max(1, 1/h^k)}{1 - (3/2)c_1 h} \leq 2 K h^{k+1} \max \left(1, \frac{1}{h^k} \right) \]

**Lemma 2.** For \(0 < \theta \leq \pi/2, 1 < \theta/\sin \theta \leq \pi/2\).

**Proof.**

\[ \frac{\pi}{2} = \frac{\pi/2}{\sin \pi/2}, \quad \lim_{\theta \to 0} \frac{\theta}{\sin \theta} = 1 \]

and there are no critical points of \(\theta/\sin \theta\) in the open interval since \((\theta/\sin \theta)' = (1/\sin \theta)(1 - \theta \cotan \theta)\) and \(\theta \cotan \theta < 1\) for \(0 < \theta < \pi/2\) since \(\arctan x < x\) in this range.

Let \(h^* = a/2 \sin \Lambda_{f, z_0}\).

**Lemma 3.** Let \(0 < h < h^*\). Let \(z_n = f_{h_k}(z_0)\). Then for all \(0 < h < h^*\),

\[ 0 \leq n-1 \leq \frac{\Lambda_{f, z_0}}{2} \frac{1}{2K} \frac{h^k}{h^{k+1}}, \quad \Lambda_{f, z_{n-1}} \leq \frac{\Lambda_{f, z_0}}{2} \]

and

\[ \left| \frac{f(z_n)}{f(z_0)} \right| < \left(1 - \frac{c_1 h}{2}\right)^n. \]

**Proof.** First note that if \(\Lambda_{f, z_k} \geq 1/2 \Lambda_{f, z_0}\) then

\[ h_{1(f, z_k)} \geq \sin 1/2 \Lambda_{f, z_0} > 1/2 \sin \Lambda_{f, z_0} \]

by Lemmas 2 and 3 of section 3 so

\[ h^* = a/2 \sin \Lambda_{f, z_0} < a \min(1, h_{1(f, z_k)}) \]

and

\[ \left| \frac{\text{arg} f(z_{k+1})}{f(z_k)} \right| < 2 K h^{k+1} \max \left(1, \frac{1}{h^k} \right) = 2 K \frac{h^{k+1}}{h^k}. \]

We may proceed by induction as long as

\[ \Lambda_{f, z_0} - (n-1) \frac{2 K h^{k+1}}{h^k} > \frac{\Lambda_{f, z_0}}{2} \quad \text{or} \quad n-1 \leq \frac{\Lambda_{f, z_0}}{2} \frac{1}{2K} \frac{h^k}{h^{k+1}}. \]

**Proof of Theorem 2.**

\[ h^* = a/2 \sin \Lambda_{f, z_0} \geq a/2 \frac{2}{\pi} \Lambda_{f, z_0} = \frac{a}{\pi} \Lambda_{f, z_0}. \]
Let $0 < h < h^*$. Then for all
\[ n - 1 \leq \frac{1}{4K} \left( \frac{a}{\pi} \right)^k \frac{A_{j, x_0}^{k+1}}{h^{k+1}} \] we have
\[ \frac{f(z_0)}{f(z)} < \left(1 - \frac{c_1 h}{2}\right)^n. \]

So to have an integer $n$ such that
\[ |f(z_0)| < \left(1 - \frac{c_1 h}{2}\right)^n |f(z_0)| \leq L \] we want
\[ \left(1 - \frac{c_1 h}{2}\right)^n \leq \frac{L}{|f(z_0)|}. \]

or
\[ n \log \left(1 - \frac{c_1 h}{2}\right) \leq \log \frac{L}{|f(z_0)|}. \]

Thus it suffices to have
\[ n \geq \frac{\log |f(z_0)|}{L} \frac{c_1 h/2}{|f(z_0)|} \]

To take $n$ this large it suffices to have
\[ \frac{1}{4K} \left( \frac{a}{\pi} \right)^k \frac{A_{j, x_0}^{k+1}}{h^{k+1}} > n - 1, \]

so it suffices to have
\[ \frac{1}{4K} \left( \frac{a}{\pi} \right)^k \frac{A_{j, x_0}^{k+1}}{h^{k+1}} \geq \frac{\log |f(z_0)|}{L} \frac{c_1 h/2}{|f(z_0)|} \]

or
\[ h^k \leq \frac{(c_1/8K)(a/\pi)^k A_{j, x_0}^{k+1}}{\log |f(z_0)|/L} \]

So we have proven. If
\[ 0 < h \leq \left( \frac{c_1}{8K} \right)^{1/k} a \left( \frac{A_{j, x_0}^{k+1}}{\pi \log |f(z_0)|/L} \right)^{1/k}, \]

then $|f(z_0)| < L$ for
\[ n = \left[ \frac{(2/c_1) \log |f(z)|/L}{h} \right]. \]

Take
\[ h = \left( \frac{c_1}{8K} \right)^{1/k} a \left( \frac{A_{j, x_0}^{k+1}}{\pi \log |f(z_0)|/L} \right)^{1/k} \]
which gives $|f(z_n)| < L$ for
\[
\eta = \left[ \frac{8K}{c_1} \right]^{1/k} 2\pi \left( \frac{\log |f(z_0)|/L}{A_{f, z_0}} \right)^{1+1/k},
\]
