Boundary value problems for non-parametric surfaces of prescribed mean curvature

<http://www.numdam.org/item?id=ASNSP_1976_4_3_3_501_0>
Boundary Value Problems for Non-Parametric Surfaces of Prescribed Mean Curvature.

ENRICO GIUSTI (*)

dedicated to Hans Lewy

0. – Introduction.

The equation of surfaces of prescribed mean curvature:

\[ \text{div} \, T \mathbf{u} = \sum_{i=1}^{n} \frac{\partial}{\partial x_i} \left\{ \frac{\partial \mathbf{u}}{\partial x_i} \sqrt{1 + |\nabla \mathbf{u}|^2} \right\} = H(x, \mathbf{u}) \]

has received considerable attention, in particular in connection with the Dirichlet problem, i.e. the problem of the existence of a solution to the equation (0.1) in an open set \( \Omega \), taking prescribed values at the boundary.

For the two-dimensional case the theory was initiated by Bernstein at the beginning of the century, and received contributions from various authors. On the contrary, the general \( n \)-dimensional problem has been successfully studied only recently; we shall mention the work of Jenkins and Serrin [17] in the case of minimal surfaces \( (H = 0) \), and of Serrin [25] for general \( H \).

The method of Serrin is based on \textit{a-priori} bounds for solutions of the Dirichlet problem for equation (0.1), in view of an application of the Leray-Schauder fixed point theorem. This allows to prove the existence of a \( C^2 \) solution to the problem, provided some conditions are satisfied, involving the function \( H(x, \mathbf{u}) \) and the mean curvature \( K(x) \) of \( \partial \Omega \).

In the meantime, a different approach to the Dirichlet problem for equation (0.1) was developed, starting from the observation that (0.1) is the Euler
equation for the functional

$$\int_{\Omega} \sqrt{1+|Du|^2} + \int_{\Omega} \lambda(x,u) \, dx$$

where $\lambda(x,t) = \int_{0}^{t} H(x,s) \, ds$. Euristic considerations (see [15]) suggest including the boundary datum $\varphi$ in the functional, and hence looking for a minimum of

$$J_1(u) = \int_{\Omega} \sqrt{1+|Du|^2} + \int_{\Omega} \lambda(x,u) \, dx + \int_{\partial\Omega} |u - \varphi| \, dH_{n-1}$$

in the class $BV(\Omega)$ of function with bounded variation in $\Omega$.

This variational approach to the Dirichlet problem (see [15], [11] and [23]) permits separate discussion of the assumptions on the mean curvature function $H(x,u)$ and on the boundary mean curvature $K(x)$, so that one can obtain sharp (and in many cases necessary and sufficient) conditions for the existence of a minimum for $J_1$. These conditions do not involve the mean curvature of the boundary.

A careful use of the a-priori estimate for the gradient (see [18], [30] and [3]) shows that the solution $u(x)$ is smooth in $\Omega$, and is a solution of equation (0.1). If in addition $\varphi$ is continuous and

$$|H(x,\varphi(x))| < (n-1) K(x)$$

at every point $x \in \partial\Omega$, then $u(x) = \varphi(x)$ at $\partial\Omega$ (see [23]) and hence is a "classical" solution to the Dirichlet problem.

The two methods outlined above have been successfully applied to the problem of capillary free surfaces. In this case one looks for a solution to (0.1), with $H(x,u) = 2u$, subject to the boundary condition

$$-Tu \cdot v = -\sum_{i=1}^{n} v \frac{\partial u}{\partial x_i} \sqrt{1+|\nabla u|^2} = \kappa \quad \text{in} \quad \partial\Omega$$

where $v$ is the exterior normal, and $\kappa$ is the cosine of the (prescribed) angle between the surface $y = u(x)$ and the boundary of the cylinder $\Omega \times \mathbb{R}$.

For this problem, variational results have been obtained in [4], minimizing the functional

$$J_2(u) = \int_{\Omega} \sqrt{1+|Du|^2} + \int_{\Omega} u^2 \, dx + \int_{\partial\Omega} \kappa u \, dH_{n-1}$$
and at the same time the classical approach has been shown to work in [31] (see also [27] and [26]).

The situation is quite different when a mixed boundary value problem is considered:

\[
\begin{aligned}
\text{div } Tu &= H(x, u) & \text{in } \Omega \\
u &= \varphi & \text{in } \partial_{1}\Omega \\
-Tu \cdot n &= \kappa & \text{in } \partial_{2}\Omega
\end{aligned}
\]

(0.4)

with \(\partial_{1}\Omega \cup \partial_{2}\Omega = \partial \Omega\). In this case, when singularities at points of \(\overline{\partial_{1}\Omega} \cap \partial_{2}\Omega\) can possibly occur, the classical method seems to be hardly applicable as it is; on the contrary one can show the existence of a minimum for the functional

\[
\mathcal{F}(u) = \int_{\Omega} \left( \sqrt{1 + |Du|^2} + \int_{\Omega} \lambda(x, u) \, dx + \int_{\partial_{1}\Omega} |u - \varphi| \, dH_{n-1} + \int_{\partial_{2}\Omega} \kappa u \, dH_{n-1} \right).
\]

The aim of this paper is to prove such existence results under sharp conditions for the functions \(H\) and \(\kappa\). As \(\mathcal{F}\) reduces to \(J_{1}\) or to \(J_{2}\) when \(\partial_{2}\Omega\) or \(\partial_{1}\Omega\) is empty, we shall find the existence of a solution with pure Dirichlet or capillarity boundary conditions. We want to observe that our results are significantly new also in these situations.

The paper is divided in four sections. The first is devoted to the assumptions on \(H\) and \(\kappa\), and to the discussion of a variety of special cases. In chapter 2 we prove the existence of a minimum for the functional \(\mathcal{F}\). After a brief discussion of the regularity of the solution in \(\Omega\) and at \(\partial_{1}\Omega\), we refine our method in order to treat some borderline situations, including the capillary free surfaces with \(|\kappa| = 1\) (compare [7]; see also [8] for an application of the results of ch. 4).

In conclusion, we shall get a quite general existence result for the problem (0.4). The solutions to this problem are regular in \(\Omega\), and at interior points of \(\partial_{1}\Omega\), provided (0.2) holds. The regularity at \(\partial_{2}\Omega\) remains still an open problem; a special case (\(\kappa = 0\)) is discussed in [16].

I wish to thank R. Finn for his stimulating remarks.

1. – The variational problem.

1.1. Throughout this paper we shall denote by \(\Omega\) a bounded connected open set in \(\mathbb{R}^n\), \(n \geq 2\), with Lipschitz-continuous boundary \(\partial \Omega\). We will write \(\partial \Omega = \partial_{1}\Omega \cup \partial_{2}\Omega\), where \(\partial_{1}\Omega\) is the intersection of \(\partial \Omega\) with a bounded
open set $A_1$, such that the set
\[ \Omega_1 = \Omega \cup A_1 \]
is connected. We suppose that $H_{n-1}(\partial_1 \Omega \cap \partial_2 \Omega) = 0$, and that $\partial_2 \Omega$ coincides with the closure of its interior.

We shall discuss the existence of a minimum for the functional
\[
F(u) = \int_{\partial} \sqrt{1 + |Du|^2} + \int_{\partial} \lambda(x, u) \, dx + \int_{\partial} |u - \varphi| \, dH_{n-1} + \int_{\partial} \kappa u \, dH_{n-1}
\]
in the class $BV(\Omega)$, of functions of bounded total variation in $\Omega$.

It can be useful to recall that the symbol
\[ \int_{\partial} \sqrt{1 + |Du|^2} \]
means the total variation in $\Omega$ of the vector-valued measure whose components are the Lebesgue measure in $\mathbb{R}^n$ and the derivatives $D_i u$ of $u$:
\[ \int_{\partial} \sqrt{1 + |Du|^2} = \sup \left\{ \int_{\partial} \left( g_0 + \sum_{i=1}^n uD_i g_i \right) \, dx : g_i \in C^1(\partial \Omega); \sum_{i=0}^n g_i^2 < 1 \right\} . \]
The integrals on $\partial \Omega$ have sense as every function of bounded variation has a trace on $\partial \Omega$, which we denote also by $u$, in $L_1(\partial \Omega)$ [21].

1.B. Let
\[ \lambda(x, t) = \int_0^t H(x, s) \, ds , \]
and let $u(x)$ be a function of class $C^\infty(\overline{\Omega})$, a minimum for the functional $F(u)$. It is clear that $u(x)$ satisfies the equation
\[
\sum_{i=1}^n D_i \left\{ D_i u / \sqrt{1 + |Du|^2} \right\} = H(x, u(x))
\]
and the boundary conditions:
\[ - \sum_{i=1}^n v_i D_i u / \sqrt{1 + |Du|^2} = \kappa(x) \quad \text{in} \ \partial_2 \Omega . \]
Let $B$ be a Caccioppoli set; i.e. a Borel set whose characteristic function $\varphi_B$ has distributional derivatives which are measures of bounded total variation. We can integrate (1.2) over $B$ to get:

$$
\int_B H(x, u(x)) \, dx = \int_{\Omega} \left( D_i u \sqrt{1 + |Du|^2} \right) D_i \varphi_B - \int_{\partial \Omega} \varphi_B \kappa dH_{n-1}.
$$

Let $t_0 = \sup_{\partial \Omega} |u|$ and suppose $H(x, t)$ is a non-decreasing function of $t$. We have:

$$
\int_B H(x, t_0) \, dx + \int_{\partial \Omega} \kappa \varphi_B dH_{n-1} \geq -(1 - \epsilon_0) \int_{\partial \Omega} |D\varphi_B|
$$

and

$$
\int_B H(x, -t_0) \, dx + \int_{\partial \Omega} \kappa \varphi_B dH_{n-1} \leq (1 - \epsilon_0) \int_{\partial \Omega} |D\varphi_B|
$$

for every Caccioppoli set $B \subset \Omega$, where

$$
1 - \epsilon_0 = \sup_{\partial \Omega} \left\{ |Du| / \sqrt{1 + |Du|^2} \right\}
$$

1.C. We will prove the existence of a minimum for the functional $\mathcal{F}(u)$ under the following assumptions on the functions $H$ and $\kappa$:

(1.3) $\kappa(x)$ is a bounded measurable function in $\partial_\Omega \Omega$. $H(x, t)$ is a function defined in $\Omega \times \mathbb{R}$, which is non-decreasing in $t$ for almost every $x \in \Omega$, and belongs to $L_\infty(\Omega)$ for every $t \in \mathbb{R}$.

(1.4) There exist two positive constants $\epsilon_0$ and $t_0$ such that for every Caccioppoli set $B \subset \Omega$ we have:

(1.4') \hspace{0.5cm} \int_B H(x, t_0) \, dx + \int_{\partial \Omega} \kappa \varphi_B dH_{n-1} \geq -(1 - \epsilon_0) \int_{\partial \Omega} |D\varphi_B|$

(1.4") \hspace{0.5cm} \int_B H(x, -t_0) \, dx + \int_{\partial \Omega} \kappa \varphi_B dH_{n-1} \leq (1 - \epsilon_0) \int_{\partial \Omega} |D\varphi_B|

The meaning of assumption (1.3) is clear as it implies that the functional $\mathcal{F}$ is convex. On the other hand condition (1.4), which we have shown to be necessary for the existence of a smooth minimum, can appear somewhat involved and artificial, so that it is advisable to illustrate in some detail its meaning and generality. For that we shall postpone the proof of the existence theorem to the next chapter and we will devote this section to a complete discussion of some particular hypotheses leading to (1.4).
1.D. Let us start from the Dirichlet problem. We have the following

**Proposition 1.1.** Let

\[ h(x) = \lim_{t \to -\infty} H^-(x, t) \]
\[ k(x) = \lim_{t \to +\infty} H^+(x, t) \]

where \( H^+ = \max(H, 0) \) and \( H^- = \min(H, 0) \).

Suppose that

\[ \partial_2 \omega = 0. \]

Then (1.4) is satisfied.

**Proof.** Since \( |H^-(x, t)| \) monotonically decreases to \( |h(x)| \) we have:

\[ \|h\|_{L_2(\Omega)} \leq n \omega_n^{1/n} \]

and similarly

\[ \|k\|_{L_2(\Omega)} \leq n \omega_n^{1/n} \]

whence there exist \( t_0 \) and \( \varepsilon_0 > 0 \) such that

\[ \|H^-(x, t_0)\|_{L_2(\Omega)} \leq (1 - \varepsilon_0) n \omega_n^{1/n} \]
\[ \|H^+(x, -t_0)\|_{L_2(\Omega)} \leq (1 - \varepsilon_0) n \omega_n^{1/n}. \]

Let \( B \subset \Omega \) be a Caccioppoli set; we have

\[ \int_B H(x, t_0) dx > \int_B H^-(x, t_0) dx > (1 - \varepsilon_0) n \omega_n^{1/n} (\text{meas } B)^{1-1/n} \]

and (1.4') follows at once from the isoperimetric inequality:

\[ (\text{meas } B)^{1-1/n} < n^{-1} \omega_n^{-1/n} \int_{\partial B} |D\varphi| \cdot \]

A similar argument lead to (1.4'). Q.E.D.
We remark that if $H$ does not depend on $t$, conditions (1.5) and (1.6) reduce to the assumptions of [1] (see also [11]):

$$\int_\Omega |H^{\pm}(x)|^n \, dx < \omega_n.$$ 

Another interesting situation is

$$H(x, t) = a(x) t + b(x)$$

with $a$ and $b$ in $L_n(\Omega)$, and $a(x) > 0$. It is clear from the proposition that no condition has to be imposed on $b(x)$ if $a(x) > 0$ almost everywhere; if we denote by $A$ the zero set of $a(x)$, condition (1.4) will be satisfied if

$$\|b^{\pm}\|_{L_n(A)} < \omega_n^{1/n}.$$ 

1.6. We shall discuss now the general case. For that we remember the following

**Lemma 1.1 (Sobolev-Poincaré inequality).** Let $\Omega$ be a connected bounded open set with Lipschitz-continuous boundary and let $w \in BV(\Omega)$. Then

$$\left\{ \int_\Omega |w - w_\Omega|^{n-1} \, dx \right\}^{1/(n-1)} \leq c_1(\Omega) \left[ Dw \right]$$

where $w_\Omega$ is the mean value of $w$ in $\Omega$ and $c_1$ is a constant independent of $w$.

As a corollary we get easily, taking $w = \varphi_A$, the inequality

$$\left( \text{meas } A \right)^{1-1/n} \leq 2c_1 \left[ D\varphi_A \right]$$

for every Caccioppoli set $A$ with $\text{meas } A \leq \frac{\text{meas } \Omega}{2}$.

For $x \in \partial \Omega$ let $B(x, r)$ be the ball of radius $r$ centered at $x$, and let

$$\Omega(x, r) = \Omega \cap B(x, r).$$

We introduce the function

$$q(x) = \limsup_{r \to 0^+} \left\{ \int_{\Omega(x, r)} \varphi_A dH_{n-1} \left[ D\varphi_A \right]; A \subset \Omega(x, r), \ \text{meas } A > 0 \right\}.$$ 

Let us start with a necessary condition.
PROPOSITION 1.2. Let assumption (1.4) be satisfied and let \( \kappa \) be continuous on \( \partial_2 \Omega \). Then for every \( x \in \partial_2 \Omega \) we have

\[
\varrho(x) |\kappa(x)| < 1 - \varepsilon_0.
\]

PROOF. We can suppose \( \kappa(x) \neq 0 \). Let \( r \) be a positive number such that

\[
\text{meas } \Omega(x, r) < \text{meas } \Omega/2,
\]

and let \( A \subset \Omega(x, r) \).

We have from (1.8):

\[
\int_A |H(x, \pm t_0)| dx < 2c_1 \min \int_{\partial_1} |D\varphi_A|
\]

where

\[
m_r = \max \left\{ \|H(x, t_0)\|_{L_1(\partial(x, r))}, \|H(x, -t_0)\|_{L_1(\partial(x, r))} \right\}.
\]

We observe that \( m_r \) goes to zero with \( r \). Recalling condition (1.4) we get

\[
\left| \int_{\partial_1} \kappa \varphi_A dH_{n-1} \right| < (1 - \varepsilon_0 + 2c_1 m_r) \int_{\partial_1} |D\varphi_A|.
\]

On the other hand

\[
(\kappa(x)| - n_r) \int_{\partial_1} \varphi_A dH_{n-1} < \left| \int_{\partial_1} \kappa \varphi_A dH_{n-1} \right|
\]

with

\[
\lim_{r \to 0^+} n_r = 0
\]

so that in conclusion we have, for every Caccioppoli set \( A \subset \Omega(x, r) \):

\[
\int_{\partial_1} \varphi_A dH_{n-1} < \frac{1 - \varepsilon_0 + 2c_1 m_r}{|\kappa(x)| - n_r} \int_{\partial_1} |D\varphi_A|
\]

and (1.10) follows at once. Q.E.D.

1.F. In order to obtain sufficient conditions we introduce the function

\[
j(x) = \text{ess lim sup}_{y \to x} |\kappa(y)|
\]

which coincides with \( |\kappa(x)| \) whenever \( \kappa \) is continuous.
LEMMA 1.2. Suppose that there exists a positive constant $\sigma$ such that for every $x \in \partial B$ we have

$$q(x) < 1 - 2\sigma.$$

Then there exists a constant $c_2$, depending on $\kappa, \sigma$ and $\Omega$, such that for every $u \in BV(\Omega)$:

$$\left| \int_{\partial B} \kappa \, dH_{n-1} \right| \leq (1 - \sigma) \int_{\Omega_1} |Du| + c_2 \int_{\Omega_1} |u| \, dx.$$  

PROOF. We can suppose $u > 0$. Let $x_0 \in \partial B$, and for $s > 0$ let $r_s$ be such that

$$\left| \int_{\partial B} \kappa \, dH_{n-1} \right| \leq (q(x_0) + s) \int_{\Omega_1} |D\kappa|$$

for every Caccioppoli set $B \subset \Omega(x_0, r_s)$, and

$$|\kappa(y)| < j(x_0) + s$$

for almost all $y \in B(x_0, r_s) \cap \partial B$.

If $\text{spt } w \subset B(x_0, r_s)$ we have:

$$\left| \int_{\partial B} \kappa \, dH_{n-1} \right| \leq \int_0^\infty \left| \int_{\partial B} \kappa \, dH_{n-1} \right| \leq (q(x_0) + s) \int_{\Omega_1} |D\kappa|$$

where

$$W_t = \{ x \in \Omega_1 : w(x) > t \}.$$  

In conclusion, choosing $s$ small enough, we get from the coarea formula (cf. [6], 4.3.2(2)):

$$\int_{\partial B} \kappa \, dH_{n-1} \leq (1 - \sigma) \int_{\Omega_1} |Du|$$

and (1.12) is proved if $\text{spt} (w) \subset B(x_0, r_s)$.

For general $w$, let $x \in \partial B$ and let $r$ be such that (1.13) holds. We can choose a finite covering of $\partial B$ with balls $B(x_i, r_i)$ $(i = 1, 2, \ldots, N)$ and non-negative smooth functions $f_i$, with $\text{spt } f_i \subset B(x_i, r_i)$, $\sum_{i=1}^N f_i < 1$ and $\sum_{i=1}^N f_i = 1$ on $\partial B$. Writing (1.13) for each of the functions $w f_i$, and adding from 1 to $N$ we obtain at once (1.12).  Q.E.D.
**Proposition 1.3.** Let $x$ and $H$ satisfy assumption (1.3) and let

\[ q(x)j(x) < 1 - \sigma \]

for every $x \in \partial_+\Omega$.

Let $H(x, t)$ satisfy the assumptions of Proposition 1.1, i.e.

\[
\begin{cases}
\| h \|_{L_n(\Omega)} < n\omega_n^{1/n} \\
\| k \|_{L_n(\Omega)} < n\omega_n^{1/n}
\end{cases}
\]

and suppose that for almost every $x$ in a neighborhood of $\partial_+\Omega$ we have

\[ \lim_{|t| \to \infty} \text{sign}(t) H(x, t) = +\infty. \]

Then (1.4) is satisfied.

**Proof.** Let $A \subset \Omega_1$ be a closed set with $\partial_+\Omega \cap A = \emptyset$ and such that (1.16) is satisfied in $S = \Omega_1 - A$. We can suppose that $\partial S \cap \Omega_1$ is smooth and since $\partial_+\Omega$ is compact we can assume that $S$ has finitely many connected components.

As in the proof of Proposition 1.1, there exist positive numbers $t_1$ and $\epsilon_1$ such that for $t > t_1$ we have

\[ \| H^{-}(x, t) \|_{L_n(\Omega)} < (1 - \epsilon_1)n\omega_n^{1/n} \]

and

\[ \| H^{+}(x, -t) \|_{L_n(\Omega)} < (1 - \epsilon_1)n\omega_n^{1/n}. \]

Let $B$ be a Caccioppoli set in $\Omega$; we get for $t_0 > t_1$:

\[
\int_B H(x, t_0) \, dx > \int_B H(x, t_0) \, dx - n\omega_n^{1/n}(1 - \epsilon_1) (\text{meas } (B \cap A))^{1-1/n} > \\
> \int_{B \cap S} H(x, t_0) \, dx - (1 - \epsilon_1) \int_A |D\varphi_B| - (1 - \epsilon_1) \int_{\partial A} \varphi_B \, dH_{n-1}
\]

and hence

\[
\int_{\partial_+\Omega} \varphi_B \, dH_{n-1} + \int_B H(x, t_0) \, dx > \int_{\partial_+\Omega} \varphi_B \, dH_{n-1} - (1 - \epsilon_1) \int_A |D\varphi_B| + \int_{\delta} H(x, t_0) \varphi_B \, dx,
\]
where
\[
\kappa(x) = \begin{cases} 
\kappa(x) & x \in \partial_x \Omega \\
-(1 - e_1) & x \in \partial S \cap \Omega \\
0 & \text{elsewhere in } \partial S.
\end{cases}
\]
Since \(\partial S \cap \Omega_1\) is smooth we have \(q(x) = 1\) there (see 1.6 below) and therefore if \(4\varepsilon_0 = \min(\sigma, e_1)\):
\[
q(x) f(x) < 1 - 4\varepsilon_0 \quad \text{in } \partial S.
\]
Applying Lemma 1.2 we get:
\[
\left| \int_{\mathbb{S}} \kappa \varphi dH_{n-1} \right| < (1 - 2\varepsilon_0) \int_{\mathbb{S}} |D\varphi| + c_3 \int_{\mathbb{S}} \varphi d\mathbb{S}
\]
where \(c_3\) depends on \(S\) and \(\kappa\) but not on the set \(B\). In conclusion
\[
\int_{\mathbb{S}} \kappa \varphi dH_{n-1} + \int_{\mathbb{S}} H(x, t_0) d\mathbb{S} > -(1 - 2\varepsilon_0) \int_{\mathbb{S}} |D\varphi| + \int_{\mathbb{T}_1} H(x, t_0) \varphi d\mathbb{S} - c_3 \int_{\mathbb{S}} \varphi d\mathbb{S}
\]
and in order to prove (1.4) we have only to show that it is possible to choose \(t_0 > t_1\) in such a way that
\[
(1.17) \quad \int_{\mathbb{S}} (H(x, t_0) - c_2) \varphi d\mathbb{S} + \varepsilon_0 \int_{\mathbb{S}} |D\varphi| > 0
\]
Let \(\Sigma\) be a connected part of \(S\), and for \(t > t_1\) let
\[
\Sigma_t = \{x \in \Sigma: H(x, t) < 2\varepsilon_0\},
\]
\[
f(x, t) = \min \{H(x, t) - c_2, 0\}.
\]
We have
\[
\lim_{t \to \infty} \text{meas } \Sigma_t = 0
\]
\[
\lim_{t \to \infty} \|f(x, t)\|_{L_n(\Sigma)} = 0
\]
and hence we can find a number \(t_2\) such that for \(t > t_2\):
\[
(1.18) \quad \text{meas } \Sigma_t < \text{meas } \Sigma/4
\]
\[
(1.19) \quad \|f(x, t)\|_{L_n(\Sigma)} < \min \left\{ c_2 \left( \frac{\text{meas } \Sigma}{4} \right)^{1/n}, \frac{\varepsilon_0}{2c_1(\Sigma)} \right\}.
\]
We discuss separately two cases:

(I) \[ \text{meas } B \cap \Sigma > \text{meas } \Sigma / 2. \]

We have

\[
\int_{\Sigma} \{ H(x, t) - c_2 \} \varphi_B \, dx > c_2 \text{meas } \Sigma / 4 + \int f(x, t) \, dx >
\]

\[
> c_2 \text{meas } \Sigma / 4 - \| f(x, t) \|_{L^2(\Sigma)} \left( \frac{\text{meas } \Sigma}{4} \right)^{1-1/n} > 0
\]

(II) \[ \text{meas } B \cap \Sigma < \text{meas } \Sigma / 2. \]

In this case we use (1.8) and we get

\[ (\text{meas } B \cap \Sigma)^{1-1/n} < 2c_1(\Sigma) \int_{\Sigma} |D\varphi_B| \]

and therefore

\[
\int_{\Sigma} \{ H(x, t) - c_2 \} \varphi_B \, dx > \int f(x, t) \, dx > \| f(x, t) \|_{L^2(\Sigma)} 2c_1 \int_{\Sigma} |D\varphi_B| \]

whence in both cases we have for \( t > t_2 \).

\[ (1.20) \int_{\Sigma} \{ H(x, t) - c_2 \} \varphi_B \, dx > -c_2 \int_{\Sigma} |D\varphi_B|. \]

Since there are only finitely many connected open sets \( \Sigma \subset S \), we get easily (1.17) with \( t_0 = \max t_2 \), and hence (1.4').

In a similar way one can prove (1.4''), thus getting the full result. Q.E.D.

1.6. We conclude this chapter with a computation of the function \( q(x) \) in various situations.

It is easily seen that we have always \( q(x) > 1 \).

**Proposition 1.4.** Let \( \partial \Omega \) be of class \( C^1 \) in a neighborhood of \( x_0 \in \partial \Omega \). Then \( q(x_0) = 1 \).

**Proof.** We can suppose that \( x_0 = 0 \) and that \( \partial \Omega \) can be represented as the graph of a function \( f(x') \), \( x' = (x_1, x_2, \ldots, x_{n-1}) \), such that \( f(0) = 0 \), \( Df(0) = 0 \) and that

\[ x_n > f(x') \quad \text{in } \Omega(0, r). \]
Let \( A \subset \Omega(0, r) \) and let \( \partial_A = \{ x \in \partial \Omega : \varphi_A(x) = 1 \} \) (we remember that \( \varphi_A(x) \) is the trace of \( \varphi_A \) on \( \partial \Omega \)). Let \( \pi_A \) be the projection of \( \partial_A \) on the hyperplane \( x_n = 0 \). We have:

\[
\int_{\partial \Omega} \varphi_A dH_{n-1} = H_{n-1}(\partial_A) = \int_{\pi_A} \sqrt{1 + |Df|^2} \, dx
\]

If we set \( M_r = \sup \{ |Df(x')|, |x'| < r \} \) we get \( \lim_{r \to 0} M_r = 0 \) and

\[
\int_{\partial \Omega} \varphi_A dH_{n-1} < (1 + M_r) H_{n-1}(\pi_A).
\]

On the other hand

\[
\int_{\Omega} |D\varphi_A| > H_{n-1}(\pi_A)
\]

and letting \( r \to 0 \) we obtain \( q(x_0) = 1 \). Q.E.D.

Another situation in which \( q(x_0) = 1 \) is when the mean curvature of \( \partial \Omega \) is bounded from above in a neighborhood of \( x_0 \). More precisely we have

**Proposition 1.5.** Let there exist \( R > 0 \) and a function \( K(x) \) in \( L_1(\Omega_R) \) \((\Omega_R = \Omega(x_0, R))\) such that

\[
(1.21) \quad \int_{\partial_R} |D\varphi_{\partial_R}| - \int_{\partial_R} K \, dx \leq \int_{\partial_R} |D\varphi| - \int_{\partial_R} K \, dx
\]

for every set \( L \subset \Omega_R \), coinciding with \( \Omega_R \) outside some compact set in \( B_R \).

Then \( q(x_0) = 1 \).

**Proof.** Let \( r < R \) and let \( A \subset \Omega_r \). From (1.21) with \( L = \Omega_R - A \) we get easily

\[
\int_{\partial A} \varphi_A dH_{n-1} - \int_{\partial A} |D\varphi_A| < \int_{\partial A} K \, dx < \|K\|_{L_1(\Omega)}(\text{meas } A)^{1-1/n}.
\]

If \( r \) is small enough we have \( \Omega_r < \text{meas } \Omega_R/2 \) and hence from (1.8):

\[
\int_{\partial A} \varphi_A dH_{n-1} \leq \{1 + 2c_1(\Omega_R)\|K\|_{L_1(\Omega)}\} \int_{\partial A} |D\varphi_A|
\]

and letting \( r \to 0 \) we get \( q(x_0) = 1 \). Q.E.D.

To conclude this section let us calculate the function \( q(x) \) at the vertex of an angular region.
Let $\Omega$ be the set $\{x \in \mathbb{R}^2: x_2 > L|x_1|\}$ and let $x_0 = 0$. It is evident that the supremum in (1.9) is attained when $A$ is the triangle

$$A = \{x \in \mathbb{R}^2: L|x_1| < x_2 < Lr/\sqrt{1 + L^2}\}$$

For such set we have:

$$\int_{\partial A} q \, dH_{n-1} = 2r$$
$$\int_{\partial A} |Dq| = 2r/\sqrt{1 + L^2}$$

and hence

$$q(0) = \sqrt{1 + L^2}$$

in agreement with the results of Emmer [4].

It can be interesting to remark that if instead of $\Omega$ we consider the set $A = \mathbb{R}^2 - \Omega$, we get $q(0) = 1$.

2. - Existence of a minimum.

2.A. We will show in this section that conditions (1.3) and (1.4) of section 1.C are sufficient to guarantee the existence of a minimum for the functional

$$F(u) = \int_{\Omega} \sqrt{1 + |Du|^2} + \int_{\partial \Omega} \lambda(x, u) \, dx + \int_{\partial \Omega} |u - \varphi| \, dH_{n-1} + \int_{\mathbb{R}^2} \varphi \, dH_{n-1}$$

in the class $BV(\Omega)$. To be precise we have the following

**Theorem 2.1.** Let $\Omega$ be a bounded connected open set with locally Lipschitz-continuous boundary $\partial \Omega$, and let $\lambda$ and $H$ be two functions satisfying conditions (1.3) and (1.4) of section 1.C. Let $\varphi$ be a function in $L_1(\partial \Omega)$. Then the functional $F(u)$ has a minimum in the class $BV(\Omega)$.

The proof of Theorem 2.1 will take all this chapter.

The first step is quite usual in the theory of non-parametric minimal surfaces, and consists in a suitable handling of the integral involving the function $\varphi$.

Since $\varphi$ is in $L_1(\partial \Omega)$, there exists a function $f(x)$ in the Sobolev space $H^1_1(\Omega_1)$ such that $\varphi$ is the trace of $f$ on $\partial_1 \Omega$ [9]. If we denote by $w$ the function

$$w(x) = \begin{cases} u(x) & x \in \Omega \\ f(x) & x \in \Omega_1 - \Omega \end{cases}$$
we have [21] \( w \in BV(\Omega_1) \) and

\[
(2.2) \quad \int_{\Omega_i} \sqrt{1 + |Dw|^2} dx = \int_{\Omega_i} \sqrt{1 + |Du|^2} + \int_{\Omega_i} \sqrt{1 + |Df|^2} dx + \int_{\partial \Omega_i} |u - \eta| d\mathcal{H}^{n-1}
\]

The problem of minimizing the functional \( \mathcal{F} \) in \( BV(\Omega) \) is thus reduced to a minimum problem for the new functional

\[
(2.3) \quad \mathcal{G}(u) = \int_{\Omega_i} \sqrt{1 + |Du|^2} + \int_{\partial \Omega_i} \lambda(x, u) dx + \int_{\partial \Omega_i} \eta u d\mathcal{H}^{n-1}
\]

in the class

\[
(2.4) \quad W = \{ w \in BV(\Omega_i) : w = f \text{ in } \Omega_i - \Omega \}.
\]

We remark that when \( \partial_i \Omega = \emptyset \) the functionals \( \mathcal{F} \) and \( \mathcal{G} \) coincide, and that \( W = BV(\Omega) \) in this case.

2.B. Let us show first that \( \mathcal{G}(u) \) is bounded from below in \( W \).

**LEMMA 2.1.** Let \( H \) and \( \lambda \) satisfy (1.3) and (1.4). Then for every function \( v \in BV(\Omega) \) we have

\[
(2.5) \quad \int_{\Omega_i} \lambda(x, v) dx + \int_{\partial \Omega_i} \eta v d\mathcal{H}^{n-1} \geq - (1 - \varepsilon_0) \left( \int_{\Omega_i} |Du| + \int_{\partial \Omega_i} |v| d\mathcal{H}^{n-1} \right) - c_3
\]

where \( c_3 \) is a constant independent of \( v \).

**PROOF.** We extend \( v \) as zero outside \( \Omega \). Let us suppose first \( v \geq 0 \). Setting

\[
V_i = \{ x \in \Omega_i : v(x) > t \}
\]

we get

\[
\int_{\Omega_i} \lambda(x, v) dx + \int_{\partial \Omega_i} \eta v d\mathcal{H}^{n-1} = \int_0^\infty \left( \int_{\Omega_i} H(x, t) dx + \int_{\partial \Omega_i} q \eta x d\mathcal{H}^{n-1} \right) dt.
\]

On the other hand:

\[
\int_0^t \left( \int_{\Omega_i} H(x, t) dx + \int_{\partial \Omega_i} q \eta x d\mathcal{H}^{n-1} \right) dt.
\]
so that from (1.4'):

\[ (2.6) \quad \int_{\Omega} \lambda(x, v) \, dx + \int_{\partial \Omega} \nabla v \cdot dH_{n-1} > - \epsilon_{0} - (1 - \epsilon_{0}) \int_{0}^{t_{0}} \int_{\Omega} |Dv_{r_{1}}| \, dx \]

where

\[ c_{e} = t_{0} H_{n-1}(\partial_{2} \Omega) + \int_{0}^{t_{0}} \int_{\Omega} \frac{H(x, t)}{t} \, dx . \]

In general we have (2.6) for \( v_{+} = \max(v, 0) \), while for \( v_{-} = \min(v, 0) \) we get:

\[ (2.7) \quad \int_{\Omega} \lambda(x, v_{-}) \, dx + \int_{\partial \Omega} \nabla v_{-} \cdot dH_{n-1} > - c_{5} - (1 - \epsilon_{0}) \int_{-\infty}^{t_{0}} \int_{\Omega} |Dv_{r_{1}}| . \]

From (2.6) and (2.7) we get at once (2.5), recalling the coarea formula:

\[ \int_{\Omega} |Dv| + \int_{\partial \Omega} |v| \, dH_{n-1} = \int_{-\infty}^{t_{0}} \int_{\Omega} |Dv_{r_{1}}| \quad \text{Q.E.D.} \]

From the preceding lemma we obtain at once the inequality

\[ (2.8) \quad \mathcal{G}(u) > \epsilon_{0} \int_{\Omega_{1}} \sqrt{1 + |Du|^{2}} - c_{e} \]

for every \( u \in W \), \( c_{e} \) being a constant independent of \( u \).

**Lemma 2.2.** Let \( \nu \) and \( H \) satisfy conditions (1.3) and (1.4). Then for every \( \delta > 0 \) there exists a constant \( c_{1}(\delta) \) such that for each \( w \in BV(\Omega_{1}) \), with \( w = 0 \) in \( \Omega_{1} - \Omega \), we have:

\[ (2.9) \quad \left| \int_{\partial \Omega} \nu \, dH_{n-1} \right| < (1 - \epsilon_{0}/2) \int_{S_{0}} |Dw| + c_{1}(\delta) \int_{S_{0}} |w| \, dx \]

where

\[ S_{0} = \{ x \in \Omega_{1} : \text{dist}(x, \partial_{2} \Omega) < \delta \} . \]

**Proof.** Let us suppose that \( w \geq 0 \) and that \( \text{spt} \, w \subset S_{0} \). We have from (1.4'):

\[ \int_{\partial \Omega} \nabla \cdot \nu \, dH_{n-1} > (1 - \epsilon_{0}) \int_{\Omega} |Dv_{r_{1}}| - \| H(x, t_{0}) \|_{L_{\infty}(S_{0})} (\text{meas } W_{1})^{1 - 1/n} . \]
Suppose now that $\delta_0$ is such that
\[
\text{meas } S_{\delta_0} \leq \text{meas } \Omega_1/2
\]
and
\[
\|H(x, t_0)\|_{L^2(S_{\delta_0})} \leq \varepsilon_0/4c_1.
\]
If $\delta < \delta_0$ we have from (1.8):
\[
\int_{\delta_0}^{x_{\Omega_1}} dH_{n-1} - (1 - \varepsilon_0/2) \int_{\Omega_1} |D\psi_{\Omega_1}|.
\]
In a similar way, using (1.4') instead of (1.4'), we obtain:
\[
\int_{\delta_0}^{x_{\Omega_1}} dH_{n-1} \leq (1 - \varepsilon_0/2) \int_{\Omega_1} |D\psi_{\Omega_1}|
\]
and hence
\[
(2.10) \quad \left| \int_{\delta_0}^{x_{\Omega_1}} dH_{n-1} \right| < (1 - \varepsilon_0/2) \int_{\Omega_1} |Dw|.
\]
Arguing as in Lemma 2.1 it is easy to see that (2.10) remains valid for a general $w$, provided $\text{spt } w \subseteq S_{\delta_0}$, with $\delta < \delta_0$.

Let $g(x)$ be a $C^\infty$ function with $g = 1$ on $\partial_+ \Omega$, $0 < g < 1$ and $\text{spt } g \subseteq S_{\delta_0}$. We have
\[
\left| \int_{\delta_0}^{x_{\Omega_1}} dH_{n-1} \right| < (1 - \varepsilon_0/2) \int_{\Omega_1} |D(\psi g)| < (1 - \varepsilon_0/2) \int_{\Omega_1} |Dw| + c_7 \int_{\Omega_1} |w| \, dx
\]
where $c_7 = c_7(\delta) = \sup_{S_{\delta_0}} |Dg|$ does not depend on $w$, so that (2.9) is proved for $\delta < \delta_0$. It is easily seen that (2.9) remains valid for every $\delta$. Q.E.D.

We can prove now the lower semicontinuity of the functional $\mathcal{G}(u)$.

**PROPOSITION 2.1.** Let $\{v_k\}$ be a sequence of functions in $W$, bounded in $L_{n-1}(\Omega_1)$, and convergent in $L_2(\Omega_1)$ to a function $v \in W$. Suppose that (1.3) and (1.4) are satisfied. Then
\[
(2.11) \quad \mathcal{G}(v) \leq \liminf_{k \to \infty} \mathcal{G}(v_k)
\]

**PROOF.** Let us prove first the lower semicontinuity of the term
\[
(2.12) \quad \int_{\bar{D}} \lambda(x, v) \, dx.
\]
For that we define, for $m > 0$, the function

$$H^{(m)}(x, t) = \begin{cases} H(x, m) & \text{if } t > m \\ H(x, t) & \text{if } |t| < m \\ H(x, -m) & \text{if } t < -m \end{cases}$$

and let

$$\lambda^{(m)}(x, t) = \int_0^t H^{(m)}(x, s) \, ds.$$ 

We have

$$\int\lambda(x, v(x)) \, dx = \sup_{m > 0} \int\lambda^{(m)}(x, v(x)) \, dx$$

and hence it is sufficient to prove the lower semicontinuity of the integral

$$\int\lambda^{(m)}(x, v) \, dx$$

for each fixed $m > 0$.

Let $v_k \to v$ in $L_1$ and let

$$\varphi_k = \max(v_k - v, 0)$$

$$\psi_k = \min(v_k - v, 0).$$

Since $\varphi_k$ and $\psi_k$ tend to zero in $L_1$ and are bounded in $L_{n/n-1}$, they converge to zero weakly in $L_{n/n-1}$. On the other hand

$$\int\lambda^{(m)}(x, v_k) \, dx - \int\lambda^{(m)}(x, v) \, dx = \int\lambda^{(m)}(x, \varphi_k) \, dx \geq \int H^{(m)}(x, -m) \varphi_k \, dx + \int H^{(m)}(x, m) \psi_k \, dx.$$ 

The right-hand side of (2.13) tends to zero as $k \to \infty$, thus proving the lower semicontinuity of (2.12).

For the remaining part of $\mathcal{G}(u)$ we use Lemma 2.2 and a technique similar to [9].

Let

$$\mathcal{E}(v) = \int_\Omega \sqrt{1 + |Dv|^2} + \int_{\partial_{n-1}} v \, dH_{n-1}$$
We have from Lemma 2.2 applied to \( w = v - v_k \):

\[
\varepsilon(v) - \varepsilon(v_k) < \int_{\Omega_1} \sqrt{1 + |Dv|^2} + \int_{\delta_1} |Dv| - \int_{\Omega_1} \sqrt{1 + |Dv_k|^2} + c_f \int_{\delta_1} |v - v_k| \, dx.
\]

Letting \( k \to \infty \) and taking into account the lower semicontinuity of the area integral we get

\[
\varepsilon(v) - \liminf_{k \to \infty} \varepsilon(v_k) < 2 \int_{\delta_1} |Dv| 
\]

for every \( \delta > 0 \), and hence

\[
\varepsilon(v) < \liminf_{k \to \infty} \varepsilon(v_k) \quad \text{Q.E.D.}
\]

2.D. The proof of Theorem 2.1 will be complete if we can show that there exists a minimizing sequence which is bounded in \( L_1(\Omega_1) \). For, let \( \{u_k\} \) be such a sequence; from (2.8) we easily see that

\[
\int_{\Omega_1} \sqrt{1 + |Du_k|^2} \leq c_1
\]

and hence \( \{u_k\} \) is bounded in \( BV(\Omega_1) \).

Passing possibly to a subsequence we can suppose that \( u_k \) converges in \( L_2(\Omega_1) \) to a function \( u \in W \). From Lemma 1.1 it follows that \( \{u_k\} \) is bounded in \( L\infty_{loc}(\Omega_1) \) and hence we can apply the semicontinuity result proved above to get the conclusion of the theorem.

Depending whether \( \partial_1 \Omega \neq \emptyset \) or \( \partial_1 \Omega = \emptyset \) we need two different arguments. The first situation can be handled by means of the following well-known result:

**Lemma 2.3.** Let \( \Omega_1 - \Omega \) be non empty and let \( w(x) \) be a function in \( BV(\Omega_1) \) with \( w = 0 \) in \( \Omega_1 - \Omega \). Then

\[
\int_{\Omega_1} |w| \, dx < c_2 \int_{\Omega_1} |Dw| 
\]

where \( c_2 \) depends only on \( \Omega \) and \( \Omega_1 \).

It is easily seen that Lemma 2.3 settles the case \( \partial_1 \Omega \neq \emptyset \). In fact every minimizing sequence is bounded in \( L_1(\Omega_1) \) since we have:

\[
\int_{\Omega_1} |u_k| \, dx < \int_{\Omega_1} |f| \, dx + c_3 \int_{\Omega_1} |Du_k| 
\]

and the last integral is bounded by (2.14).
When \( \partial_1 \Omega = 0 \) the previous lemma does not work and we need a different argument. Let us remark first that if \( \partial_1 \Omega = 0 \) condition (1.4) implies

\[
\int_\Omega H(x, t_0) \, dx + \int_{\partial \Omega} \kappa dH_{n-1} > 0
\]

(2.16)

and

\[
-\int_\Omega H(x, -t_0) \, dx - \int_{\partial \Omega} \kappa dH_{n-1} > 0
\]

(2.17)

**Lemma 2.4.** Suppose that there exists a positive number \( h_0 \) such that

\[
\int_\Omega H(x, t_0) \, dx + \int_{\partial \Omega} \kappa dH_{n-1} > h_0
\]

(2.18)

and

\[
-\int_\Omega H(x, -t_0) \, dx - \int_{\partial \Omega} \kappa dH_{n-1} > h_0
\]

(2.19)

and let \( u \in BV(\Omega) \) satisfy

\[
p(u) = \int_\Omega \lambda(x, u(x)) \, dx + \int_{\partial \Omega} \kappa u dH_{n-1} < 1
\]

Then

\[
\int_{\partial \Omega} |u| \, dx < c_1 \left\{ 1 + \int_{\partial \Omega} |Du| \right\}
\]

(2.20)

**Proof.** Let

\[
v_1 = \max(u - t_0, 0)
\]

\[
v_2 = \max(-u - t_0, 0)
\]

We have

\[
p(v_1 + t_0) - p(t_0) > \int_\Omega H(x, t_0) v_1 \, dx + \int_{\partial \Omega} \kappa v_1 dH_{n-1}
\]

and

\[
p(-v_2 - t_0) - p(-t_0) > -\int_\Omega H(x, -t_0) v_2 \, dx - \int_{\partial \Omega} \kappa v_2 dH_{n-1}.
\]

Setting

\[
\bar{v}_i = (\text{meas } \Omega)^{-1} \int_{\partial \Omega} v_i \, dx \quad (i = 1, 2);
\]
we get
\[ h_0 \bar{v}_1 < \int_\Omega [H(x, t_0) + \bar{\kappa} H_{n-1}] \bar{v}_1 \leq \int_\Omega |H(x, t_0)(\bar{v}_1 - v_1) dx + \int_\partial \Omega \bar{\kappa}(\bar{v}_1 - v_1) dH_{n-1} + p(v_1 + t_0) - p(t_0). \]

From Lemma 1.1 we obtain:
\[ \left| \int_\Omega [H(x, t_0)(\bar{v}_1 - v_1) dx \right| \leq \|H(x, t_0)\|_{L_\infty} \|v_1 - \bar{v}_1\|_{L_{n+1}} < c_{11} \int_\Omega |Du_1| \]

a similar estimate holding for the boundary integral. In conclusion
\[ h_0 \bar{v}_1 < c_{12} \int_\Omega |Du_1| + p(v_1 + t_0) - p(t_0). \]

In a similar way
\[ h_0 \bar{v}_2 < c_{12} \int_\Omega |Du_2| + p(-v_2 - t_0) - p(-t_0) \]

and hence
\[ (2.21) \quad h_0 (\bar{v}_1 + \bar{v}_2) < c_{14} \int_\Omega |Du| + p(v_1 + t_0) + p(-v_2 - t_0) - p(t_0) - p(-t_0). \]

On the other hand we have
\[ (\text{meas } \Omega)^{-1} \int_\Omega |u| dx < \bar{v}_1 + \bar{v}_2 + t_0 \]

and
\[ p(v_1 + t_0) + p(-v_2 - t_0) - p(t_0) - p(-t_0) = p(u) - p(u_0) \]

where
\[ u_0(x) = \max\{\min(u, t_0), -t_0\}. \]

Combining these relations we get
\[ \int_\Omega |u| dx < c_{15} \int_\Omega |Du| + c_{16} \]

since
\[ |p(u_0)| < t_0 \{H_{n-1}(\partial \Omega) + \|H(x, t_0)\|_{L_\infty} + \|H(x, -t_0)\|_{L_\infty} \} \quad \text{Q.E.D.} \]
The preceding lemma plays the role of Lemma 2.3 in the proof of Theorem 2.1. Let \( \{u_k\} \) be a minimizing sequence; we can suppose that

\[
\mathcal{G}(u_k) < \mathcal{G}(0) + 1 = \text{meas } \Omega + 1
\]

and hence

\[
p(u_k) < 1,
\]

for every \( k \). From Lemma 2.4 and (2.14) we can conclude that \( \{u_k\} \) is bounded in \( L_1(\Omega) \) and therefore we get the conclusion of Theorem 2.1.

2.F. It remains the case when \( \partial_1 \Omega = \emptyset \) and either

\[
\int_{\Omega} H(x, t) \, dx + \int_{\partial \Omega} x \, dH_{n-1} = 0
\]

or

\[
\int_{\Omega} H(x, -t) \, dx + \int_{\partial \Omega} x \, dH_{n-1} = 0
\]

for every \( t > t_0 \).

It is evident that an a-priori estimate for the \( L_1 \) norms of a general minimizing sequence cannot hold, as one can realize considering the case \( H = \chi = 0 \), and hence we need a different argument.

To be definite let us suppose that (2.22) holds for every \( t > t_0 \). Since \( H(x, t) \) is a non-decreasing function of \( t \) it follows that \( H(x, t) = H(x, t_0) \) for almost every \( x \) in \( \Omega \) and for each \( t > t_0 \).

**Lemma 2.5.** Let \( \partial_1 \Omega = \emptyset \) and let (2.22) and condition \((1.4')\) hold. Then for every Caccioppoli set \( B \subset \Omega \) we have:

\[
\left| \int_{\Omega} H(x, t_0) \, dx + \int_{\partial \Omega} \chi dH_{n-1} \right| < (1 - \epsilon_0) \int_{\Omega} |D\varphi_B|.
\]

**Proof.** Let \( B \subset \Omega \) and let \( A = \Omega - B \). We have

\[
\int_{\Omega} |D\varphi_B| = \int_{\Omega} |D\varphi_A|.
\]

From (1.4') relative to the set \( A \) we get

\[
\left| \int_{\Omega} \varphi_A H(x, t_0) \, dx + \int_{\partial \Omega} \varphi_A \chi dH_{n-1} \right| < (1 - \epsilon_0) \int_{\Omega} |D\varphi_B|.
\]
Since \( \varphi_A = 1 - \varphi_B \) in \( \Omega \), we obtain from (2.22):

\[
(2.25) \quad \int_B \varphi_B H(x, t_0) \, dx + \int_{\partial B} \chi \varphi_B \, d\mathcal{H} \leq (1 - \varepsilon_0) \int_B |D\varphi_B|
\]

and (2.24) follows at once from \((1.4')\) relative to \( B \). \( \text{Q.E.D.} \)

Let us introduce now the functional

\[
\mathcal{G}_0(u) = \int_B \sqrt{1 + |Du|^2} + \int_B H(x, t_0) u(x) \, dx + \int_{\partial B} \chi u \, d\mathcal{H}.
\]

It follows from (2.22) that

\[
\mathcal{G}_0(u) = \mathcal{G}_0(u + c)
\]

for every real number \( c \) and every \( u \in BV(\Omega) \), so that a minimum for \( \mathcal{G}_0 \) in the class

\[
V_0 = \{ v \in BV(\Omega) : \int_B v \, dx = 0 \}
\]

will be also a minimum for \( \mathcal{G}_0 \) in \( BV(\Omega) \).

The existence of a minimum for \( \mathcal{G}_0 \) in \( V_0 \) follows from (2.24) with the same argument as before; the \( L_1 \) norm of a minimizing sequence being bounded from Lemma 1.1, since \( \varepsilon_0 = 0 \).

2.G. We shall prove now an a-priori bound for the supremum of a function minimizing the functional \( \mathcal{G}(u) \). The following lemma is a simple consequence of \((1.8)\).

**Lemma 2.6.** Let \( w \in BV(\Omega) \) and let

\[
\text{meas spt}(w) < \text{meas } \Omega/2.
\]

Then

\[
(2.26) \quad \left( \int_B |w|^{s/n - 1} \, dx \right)^{-1/n} \leq 2c_1 \int_B |Dw|.
\]

**Proof.** We can suppose \( w > 0 \). We have

\[
(\text{meas } W_1)^{1 - 1/n} \leq 2c_1 \int_B |D\varphi_{W_1}|
\]

where as usual

\[
W_t = \{ x \in \Omega : w(x) > t \}
\]

and (2.26) follows as in [2], Lemma 1. \( \text{Q.E.D.} \)
The a-priori bound for a solution can now be proved using the method of [28] (see [10]).

**Theorem 2.2.** Let conditions (1.3) and (1.4) be satisfied and let \( u(x) \) be a minimum for the functional \( G(u) \). We have:

\[
\sup_{\Omega} |u| < c_{17}
\]

where \( c_{17} \) is a constant depending on \( \epsilon_0, \epsilon_0, \|u\|_{L^0} \) and on \( \sup_{\partial \Omega} |\varphi| \).

**Proof.** Let \( m_0 = \sup_{\partial \Omega} |\varphi| \); we can suppose that \( \sup_{\partial \Omega} |f| = m_0 \). Let \( k > \max(m_0, t_0) \) and let

\[
v = \min(u, k) \quad \text{and} \quad w = \max(u - k, 0) = u - v.
\]

We have as in [10]:

\[
\int_{\Omega} |Dw| - \text{meas } U_k < \int_{\Omega} \sqrt{1 + |Du|^2} - \int_{\partial \Omega} \sqrt{1 + |Dv|^2}
\]

where

\[
U_k = \{ x \in \Omega : u(x) > k \}
\]

and therefore, since \( G(u) < G(v) \):

\[
\int_{\Omega} |Dw| + \int_{\partial \Omega} H(x, t) dt + \int_{\partial \Omega} \omega \sigma H_{n-1} < \text{meas } U_k.
\]

From the very definition of \( v \) and \( w \) we get

\[
\int_{\Omega} \int_{v}^{u} H(x, t) dt \geq \int_{\Omega} H(x, t_0) w \, dx
\]

and from (1.4'):

\[
\int_{\partial \Omega} H(x, t_0) \omega dx + \int_{\partial \Omega} \omega \sigma H_{n-1} > - (1 - \epsilon_0) \int_{\partial \Omega} |Dw|
\]

so that in conclusion:

\[
(2.28) \quad \epsilon_0 \int_{\partial \Omega} |Dw| < \text{meas } U_k.
\]
On the other hand we have

\[ k \text{ meas } U_k < \| u \|_{L^p(\Omega)} \]

and hence if

\[ k > 2 \| u \|_{L^p(\Omega)} / \text{meas } \Omega \]

we get

\[ \text{meas spt}(u) < \text{meas } \Omega / 2 . \]

From Lemma 2.6 we conclude that

\[ \| u \|_{L^{n-1} \Omega} < 2 c_1 \int_{\Omega} |Dw| \]

and therefore

(2.29) \[ \int_{U_k} (u - k) \, dx < 2 c_1 \varepsilon_0^{-1} (\text{meas } U_k)^{1 + 1/n} \]

for every \( k > k_0 = \max \{ m_0, t_0, 2 \| u \|_{L^p(\Omega)} / \text{meas } \Omega \} \).

Using a well known result of Stampacchia [28] we get the estimate

\[ \sup_{\Omega} u < k_0 + 2(n + 1) c_1 \varepsilon_0^{-1} (\text{meas } \Omega)^{1/n} . \]

A similar computation gives the estimate for the infimum of \( u \) in \( \Omega \). Q.E.D.

2.3. We are now ready to prove the existence of a minimum for the functional \( G(u) \), under the condition

(2.22) \[ \int_{\Omega} H(x, t) \, dx + \int_{\partial \Omega} x \cdot dH_{n-1} = 0 \quad \text{for every } t > t_0 . \]

We observe that (2.22) implies \( H(x, t) = H(x, t_0) \) for every \( t > t_0 \), and hence \( H(x, t) < H(x, t_0) \) for each \( t \). If we set

\[ q_0 = \int_0^{t_0} \int_{\Omega} (H(x, t_0) - H(x, t)) \, dx \, dt \]

we have, for every function \( u \in BV(\Omega) \):

\[ G_0(u) < G(u) + q_0 \]

the equality holding if \( u(x) > t_0 \) a.e. in \( \Omega \).
Let now \( v(x) \) be a minimum for the functional \( G_0 \) in \( V_\varepsilon \); it follows from Theorem 2.2 that \( |v(x)| \) is bounded by some constant \( c_\varepsilon \) depending only on \( \varepsilon_0, \varepsilon_1 \) and \( \Omega \). If \( u(x) \) is a function in \( BV(\Omega) \) we have

\[
G(u) > G_0(u) - q_\varepsilon > G_0(v + c_\varepsilon + t_\varepsilon) - q_\varepsilon = G(v + c_\varepsilon + t_\varepsilon).
\]

In conclusion, the function

\[
v_\varepsilon = v + c_\varepsilon + t_\varepsilon
\]

gives the required minimum for the functional.

The proof of Theorem 2.1 is thus complete. We can summarize the results of this chapter as follows:

**Theorem 2.3.** Let \( \varphi \) and \( H \) be two functions satisfying conditions (1.3) and (1.4) of section 1.C. and let \( \varphi \) be in \( L_1(\partial \Omega) \).

The functional

\[
\mathcal{F}(u) = \int_{\Omega} \sqrt{1 + |Du|^2} + \int_{\Omega} \int_{\partial \Omega} H(x, t) dt + \int_{\partial \Omega} |u - \varphi| dH_{n-1} + \int_{\partial \Omega} \nu dH_{n-1}
\]

has a minimum in \( BV(\Omega) \).

Moreover, if \( \varphi \) is bounded, every minimum \( u \) of \( \mathcal{F} \) is bounded by a constant depending on \( \varepsilon_0, t_0, \sup_{\partial \Omega} |\varphi| \) and \( u|_{\partial \Omega} \).

In particular if \( \partial \Omega \neq \emptyset \) and \( \varphi \) is bounded, or if \( \partial \Omega = \emptyset \) and the functions \( \varphi \) and \( H \) satisfy (2.18) and (2.19) then every minimum of \( \mathcal{F} \) is bounded by a constant depending only on \( \varepsilon_0, t_0, \sup |\varphi| \) and possibly on \( h_0 \).

3. – Regularity of the solution.

3.A. The problem of the regularity of the solutions to our variational problem is still open in what concerns the regularity at the boundary \( \partial \Omega \).

On the contrary, for interior smoothness, as well as for the regularity at \( \partial \Omega \), the situation is quite satisfactory and, for instance, one can get complete results for the Dirichlet problem.

In this chapter we shall sketch briefly the ideas involved in the proof of these results, referring to [15], [13] and [23] for details.

3.B. We begin with interior regularity, and we suppose that the mean curvature function \( H(x, t) \) is Lipschitz-continuous in \( \Omega \times \mathbb{R} \).
The first step consists in the observation that if the function $u(x)$ gives a minimum for the functional $\mathcal{F}(u)$ in $BV(\Omega)$, then the set

$$U = \{(x, t) \in \Omega \times \mathbb{R} : t < u(x)\}$$

minimize the functional

$$F_K(U) = \int_K |D\varphi_U| + \int_K H(x, t) \varphi_U \, dx \, dt$$

in every compact set $K \subset \Omega \times \mathbb{R}$.

In other words we have

$$F_K(U) < F_K(V)$$

for every Caccioppoli set $V \subset \Omega \times \mathbb{R}$ and such that $\varphi_U - \varphi_V = 0$ outside the compact set $K$ (see [20]).

We can apply the results of [19] and conclude that the boundary $\partial U$ of $U$ is a regular hypersurface, except possibly for a locally compact set $\Sigma$, whose Hausdorff dimension does not exceed $n - 7$.

The argument used in [15] and [13] applies to this case also (we use again the fact that $H(x, t)$ is non-decreasing in $t$) and we conclude that the function $u(x)$ is regular (say $C^{1+\alpha}$), except for the set $N = \text{proj} \Sigma$. In addition the function $u$ belongs to the Sobolev space $H^{1,1}(\Omega)$.

In order to get the complete regularity of the function $u(x)$ one must use the a-priori inequality for the gradient (see [18] and [30]), and an approximation procedure, for which we refer to [15], [12] and [22]. The final result is the following

**Theorem 3.1.** Let Lipschitz-continuous function in $\Omega \times \mathbb{R}$ and let $u(x)$ be a minimum for the functional

$$\mathcal{F}(u) = \int_{\bar{\Omega}} \sqrt{1 + |Du|^2} + \int_{\partial \Omega} \lambda(x, u) \, dx + \int_{\partial \Omega} |u - \varphi| \, dH_{n-1} + \int_{\partial \Omega} |\kappa| \, dH_{n-1}$$

Then $u$ belongs to $C^{1+\alpha}(\Omega)$, for every $\alpha < 1$.

In addition for every $x_0 \in \Omega$ and for every $R < \text{dist}(x_0, \partial \Omega)$ we have

$$|Du(x_0)| < c_{19} \exp \{c_{20} \omega(R)/R\}$$

where $\omega(R)$ is the oscillation of $u$ in the ball $B(x_0, R)$ and $c_{19}$ and $c_{20}$ depend on $H$, $DH$ and $\sup |u|$.
3.C. It has been proved in [3] that the inequality (3.3) does not hold in general if the function $H(x, t)$ is not Lipschitz-continuous. To be precise, if $H$ does not depend on $t$ it is not sufficient to assume that $H(x)$ belongs to the Sobolev space $H^{1,\infty}$, for every $p < \infty$.

In this section we shall give an example showing that if $H$ is not Lipschitz-continuous the function $u(x)$ does not belong in general to the space $H^{1,\infty}(\Omega)$. The example will concern the one-dimensional problem, but it is easily seen that it works in any dimension.

Let

$$f(x) = \begin{cases} 
\exp\left(- (x - 1)^{-1}\right) & x > 1 \\
0 & -1 < x < 1 \\
\exp\left((x + 1)^{-1}\right) & x < -1
\end{cases}$$

If we set

$$h(t) = \begin{cases} 
0 & t = 0 \\
t \log^2 |t| (2 + \log |t|) (1 + t^2 \log^4 |t|)^{-\frac{1}{2}} & t \neq 0
\end{cases}$$

we have

$$\frac{d}{dx} (f'(1 + f'^2)^{-1}) = h(f(x)).$$

The function $h(t)$ is increasing for $|t| < T = e^{-6}$; if we set

$$Q = \{ x \in \mathbb{R} : |x| < 1 + \frac{3}{2}\}$$

we get $|f(x)| < T$ in $Q$ and hence

$$\frac{d}{dx} (f'(1 + f'^2)^{-1}) = H(f(x))$$

where

$$H(t) = \begin{cases} 
h(t) & |t| < T \\
h(T) + h'(T)(t - T) & t > T \\
h(-T) + h'(-T)(t + T) & t < -T
\end{cases}$$

The function $H(t)$ is increasing in $\mathbb{R}$ and therefore the set

$$F = \{(x, y) \in Q \times \mathbb{R} : f(x) < y < T\}$$
minimizes the functional
\[ \int_K |Dq|^p + \int_K q H(y) \, dx \, dy \]
in every compact set \( K \subseteq A = Q \times (-T, T) \).

Let
\[ v(y) = \text{sign}(y)(1 - (\log|y|)^{-1}) ; \]
we have \( v \in BV(-T, T) \) and
\[ F = \{(x, y) \in A : |y| < T, x < v(y)\} . \]

From the minimum properties of \( F \) it follows that
\[ (3.4) \quad \int_{-T}^{T} \sqrt{1 + |Dv|^2} + \int_{-T}^{T} H(y) v(y) \, dy < \int_{-T}^{T} \sqrt{1 + |Dw|^2} + \int_{-T}^{T} H(y) w(y) \, dy \]
for every \( w \in BV(-T, T) \), such that \( \text{spt}(v - w) \subseteq (-T, T) \) and such that the graph of \( w \) is contained in \( A \), i.e. \( |w| < 1 + \frac{1}{3} \).

From the convexity of the functional it follows at once that the function \( v(y) \) satisfies (3.4) for every \( w \in BV(-T, T) \) with \( \text{spt}(v - w) \subseteq (-T, T) \).

It is easily seen that \( H(y) \) is in \( H^{1,p}(-T, T) \) for every \( p < +\infty \) and \( v(y) \) does not belong to \( H^{1,1} \).

3.D. For what concerns the regularity of the solution at points of \( \partial_1 \Omega \) we refer to [23] and [13]. We have the following

**Theorem 3.2.** Let \( \partial_1 \Omega \) be of class \( C^3 \) and let \( \varphi(x) \) be a continuous function on \( \partial_1 \Omega \). Let \( x_0 \in \partial_1 \Omega \) be such that the sum of the principal curvatures of \( \partial \Omega \) at \( x_0 \) is greater than \( |H(x_0, \varphi(x_0))| \). Let \( u(x) \) minimize the functional (3.2) and let \( H(x, t) \) be continuous. Then
\[ \lim_{x \to x_0} u(x) = \varphi(x_0) . \]

If in addition \( \varphi(x) \) is of class \( C^{1,2} \) in a neighborhood of \( x_0 \) and \( H(x, t) \) is Lipschitz-continuous, then the gradient of \( u(x) \) is bounded in a neighborhood of \( x_0 \).

The first assertion of the Theorem is a special case of [23], Theorem 6; the last part can be easily proved with the method of [13] using inequality (3.3) and the bound for \( \sup |u| \).
4. Existence revisited.

4.A. In this chapter we shall come back to the existence of a minimum for the functional

$$F(u) = \int_{\Omega} \sqrt{1 + |Du|^2} + \int_{\partial \Omega} \lambda(x, u) \, dx + \int_{\partial \Omega} |u - \varphi| \, dH_{n-1} + \int_{\partial \Omega} \kappa u \, dH_{n-1}$$

with the purpose of generalizing the results of ch. 2.

We shall make the following assumptions:

(4.1) The boundary of $\Omega$, $\partial \Omega$, is a hypersurface of class $C^3$; and $\varphi(x)$ and $\kappa(x)$ are bounded measurable functions in $\partial_1 \Omega = \Omega_1 \cap \partial \Omega$ and $\partial_2 \Omega$, respectively, with $|\kappa(x)| < 1$.

$H(x, t)$ is a Lipschitz-continuous function in $\Omega \times \mathbb{R}$, non-decreasing in $t$ for every $x \in \Omega$.

(4.2) There exist two positive constants $t_0$ and $\alpha_0$ such that for every Caccioppoli set $B \subset \Omega$:

$$\left\{ \begin{array}{l}
\int_B H(x, t_0) \, dx + \int_{\partial \Omega} \kappa \varphi B \, dH_{n-1} > - \int_{\partial \Omega} |D\varphi| + 2\alpha_0 \min \{|B|, \Omega - B|\} \\
\int_B H(x, -t_0) \, dx + \int_{\partial \Omega} \kappa \varphi B \, dH_{n-1} < \int_{\partial \Omega} |D\varphi| - 2\alpha_0 \min \{|B|, \Omega - B|\}
\end{array} \right.$$ 

where we have denoted by $|B|$ the measure of $B$.

It is clear from (1.8) that condition (4.2) is more general than the corresponding assumption (1.4); in particular we are able to treat the case where $\kappa(x)$ takes the values $\pm 1$, formerly forbidden by the proposition 1.2.

From the results of [14] it is apparent that one must have quantitative conditions on the mean curvature of that part of the boundary where $\kappa(x)$ takes the values $+1$ or $-1$. For $x \in \Omega$ let $d(x) \equiv \text{dist}(x, \partial \Omega)$ and let

$$\Gamma_{+1} = \{ x \in \partial \Omega : \kappa(x) = 1 \},$$

$$\Gamma_{-1} = \{ x \in \partial \Omega : \kappa(x) = -1 \}.$$

We have:

**Proposition 4.1.** Let $x_0$ be an interior point of $\Gamma_{+1}$ and let (4.2') hold. Then

$$H(x_0, -t_0) < \Delta d(x_0) - 2\alpha_0.$$
If instead \( x_o \) is an interior point of \( \Gamma_{-1} \) and if (4.2') holds, we have:

\[
H(x_o, t_o) > -\Delta d(x_o) + 2x_o. \tag{4.4}
\]

**Proof.** Let \( B_r \) be a ball centered at \( x_o \) such that \(|B_r| < |\Omega|/2\) and \( \partial \Omega \cap B_r \subset \Gamma_{-1} \), and let \( B \subset B_r \). We have from (4.2*):

\[
\int_B \{H(x, -t_o) + 2x_o\} \, dx + \int_{\partial \Omega} \varphi \, dH_{-1} < \int_{\partial \Omega} |D\varphi_x|.
\]

Setting

\[
H_0 = \inf_{B_r} H(x, -t_o) + 2x_o
\]

we obtain

\[
\int_{\partial \Omega} \varphi \, dH_{-1} < \int_{\partial \Omega} |D\varphi_x| - H_0 |B|.
\]

Let \( Q = \mathbb{R}^n - \Omega \), and let \( A = Q \cup B \). We have

\[
\int_{\partial B_r} |D\varphi_Q| = \int_{\partial B_r} |D\varphi_Q| + \int_{\partial \Omega} |D\varphi_x| - \int_{\partial \Omega} \varphi \, dH_{-1}
\]

and hence

\[
\int_{\partial B_r} |D\varphi_Q| - H_0 |Q \cap B_r| < \int_{\partial B_r} |D\varphi_A| - H_0 |A \cap B_r|
\]

for every set \( A \supset Q \), and coinciding with \( Q \) outside \( B_r \).

The last relation implies that the sum of the principal curvatures of \( \partial \Omega \cap B_r \) does not exceed \(-H_0\); from Lemma 1.2 of [25] we conclude

\[-\Delta d(x_o) < -H_0.\]

Since \( r \) is arbitrary, we can let \( r \to 0 \), getting (4.3). With the same argument one can prove (4.4) and hence the Proposition. Q.E.D.

The preceding result justifies the additional assumption

\[
\text{(4.5) \ Supplementary condition. There exist two positive constants } \kappa_1 < 1 \text{ and } \kappa_1, \text{ and two open sets } L_{+1} \text{ and } L_{-1} \text{ such that}
\]

\[
\text{(4.5')} \kappa(x) < \kappa_1 \text{ in } \partial_2 \Omega - L_{+1}, \text{ and } H(x, -t_o) < -\Delta d(x) - 2x_1 \text{ in } L_{+1},
\]

\[
\text{(4.5$^*$')} \kappa(x) > -\kappa_1 \text{ in } \partial_2 \Omega - L_{-1}, \text{ and } H(x, t_o) > -\Delta d(x) + 2x_1 \text{ in } L_{-1}.
\]
We remark that if \( \kappa(x) \) is a continuous function and if the sets \( \Gamma_{+1} \) and \( \Gamma_{-1} \) coincide with the closure of their interior, the supplementary condition (with \( \alpha_i = \frac{1}{2} \alpha_0 \)) follows from \( (4.2) \) and Proposition 4.1.

4.B. As in ch. 1 we shall begin with a short discussion of condition \( (4.2) \).

Let us consider first the Dirichlet problem (i.e. \( \partial \Omega = \emptyset \)) for constant mean curvature \( H \), in the borderline case [3]:

\[
|H| = n \omega_n^{1/n} |\Omega|^{-1/n} .
\]

We have

\[
\int_B H \, dx = |H| |\partial B|^{1/n} |\Omega|^{1/n} (1 - |\Omega - B|/|\Omega|)^{1/n}
\]
and hence

\[
\int_B H \, dx \leq \int_{\partial \Omega} |D\varphi_B| - n^{-1} |H||\partial B|^{1/n} |\Omega - B| < 
\]

\[
\int_{\partial \Omega} |D\varphi_B| - n^{-1} |H||\Omega - B|^{-1}
\]

which gives at once \( (4.2) \).

In general, in the case of Dirichlet problem, condition \( (4.2) \) is satisfied if for some \( t_0 \) and some \( p \), \( n < p < + \infty \),

\[
H^\pm(x, \mp t_0) \in L_p(\partial \Omega) < n \omega_n^{1/n} |\Omega|^{1/n-1/n}.
\]

where, as usual, \( H^+ = \max(H, 0) \) and \( H^- = \min(H, 0) \).

The situation is more involved in the case of mixed boundary conditions. We need the following

**Lemma 4.1.** Let \( L \) be a set with \( C^2 \) boundary and let \( w \in BV(L) \). Then

\[
(4.7) \quad \int_{\partial L} |w| dH_{n-1} \leq \int_L |Dw| + c_{z_1}(L) \int_L |w| \, dx.
\]

**Proof** (see [10], Lemma 1). Let \( d_0 \) be such that the distance function \( d(x) = \text{dist}(x, \partial L) \) is of class \( C^2 \) in the strip

\[
S = \{ x \in L : d(x) < d_0 \} .
\]

Arguing as in [10], we get \( (4.7) \) with

\[
e_{z_1}(L) = d_0^{-1} + \sup_{\partial S} \max(-\Lambda d, 0) .
\]

Q.E.D.
PROPOSITION 4.2. Let $\Omega$, $x$ and $H$ satisfy assumptions (4.1) and let

$$h(x) = \lim_{t \to + \infty} H^-(x, t)$$

$$k(x) = \lim_{t \to - \infty} H^+(x, t)$$

Suppose that

$$\|h\|_{L^\infty(\Omega)} < n\omega_n^{1/n}$$

$$\|k\|_{L^\infty(\Omega)} < n\omega_n^{1/n}$$

and

$$(4.8) \quad \lim_{|t| \to + \infty} \text{sgn}(t) H(x, t) = + \infty$$

uniformly for $x$ in some neighborhood $L$ of $\partial_2 \Omega$. Then (4.2) is satisfied.

Proof. We remark that since $H$ is continuous and non-decreasing in $t$, uniform convergence in (4.8) is equivalent to pointwise convergence. Moreover, we can suppose that $\partial L$ is smooth. Arguing as in Proposition 1.3 we get the inequality:

$$\int_{\Omega} H(x, t_0) \, dx + \int_{\partial_2 \Omega} \varphi_B \, dH_{n-1} + \int_{\partial_1 L} \tilde{\varphi}_B \, dH_{n-1} - (1 - \epsilon_1) \int_{\partial_1 L} |D\varphi_B| +$$

$$+ \int_{\partial_2 \Omega} H(x, t_0) \varphi_B \, dx + \epsilon_1 \int_{\partial_1 L} \varphi_B \, dH_{n-1}$$

for every $t_0 > t_1$, where

$$\tilde{\varphi} = \begin{cases} \chi & \text{in } \partial \Omega \\ -1 & \text{in } \partial L \cap \Omega_1. \end{cases}$$

From Lemma 4.1 we obtain

$$\int_{\Omega} H(x, t_0) \, dx + \int_{\partial_2 \Omega} \varphi_B \, dH_{n-1} + \int_{\partial_1 L} |D\varphi_B| + \int_{\Omega} (H(x, t_0) - c_{\Omega_1}) \varphi_B \, dx +$$

$$+ \epsilon_1 \int_{\partial_1 L} |D\varphi_B| + \int_{\partial_1 L} \varphi_B \, dH_{n-1}$$

If we choose $t_0$ in such a way that $H(x, t_0) > c_{\Omega_1} + 1$ in $L$, we get immediately (4.2') observing that

$$\int_{\partial_2 \Omega} \varphi_B \, dH_{n-1} > n\omega_n^{1/n} |\Omega|^{-1/n} |B \cap (\Omega - L)|.$$

The proof of (4.2") is similar and will be omitted. Q.E.D.
4.C. The existence of a minimum for the functional $\mathcal{F}(u)$ with the assumptions of section 4.A. cannot be proved directly as before, because in general we don’t have an a-priori bound for the area of minimizing sequences. However, for a suitable minimizing sequence we shall prove an estimate in $BV$, from which we will derive the existence of a minimum.

The idea consists in approximating the functions $H$ and $\lambda$ by means of the functions

$$H_\varepsilon(x, t) = (1 - \varepsilon)H(x, t)$$

and

$$\lambda_\varepsilon(x) = (1 - \varepsilon)\lambda(x).$$

For small values of $\varepsilon > 0$ these new functions satisfy the hypotheses of section 4.A. and moreover conditions (1.4) of section 1.C with $\varepsilon_0 = \varepsilon$, so that the corresponding functional $\mathcal{F}_\varepsilon$ has a minimum $u_\varepsilon$ in $BV(\Omega)$ which, according to Theorems 2.3 and 3.1, belongs to the space $C^{2,\alpha}(\Omega) \cap L_\omega(\Omega)$. Due to the convexity of the functional, the minimizing function is unique up to an additive constant.

Our goal is to get a bound for $\sup_{\partial^+ \Omega} |u_\varepsilon|$, independent of $\varepsilon$. To this purpose we shall consider an auxiliary obstacle problem.

Let

$$\mathcal{G}_\varepsilon(v) = \sqrt{1 + |Dv|^2} + \int_{\partial^+ \Omega} H_\varepsilon(x, t_\varepsilon) v \, dx + \int_{\partial^+ \Omega} \lambda_\varepsilon v \, dH_{n-1}.$$

We have from (4.2')

$$\int_B H_\varepsilon(x, t_\varepsilon) \, dx + \int_{\partial^+ \Omega} \lambda_\varepsilon \varphi \, dH_{n-1} \geq (1 - \varepsilon) \int_B |D\varphi| + 2\lambda_\varepsilon(1 - \varepsilon) \min (|B|, |\Omega - B|)$$

and therefore arguing as in chapter 2 (see also [5]) we can conclude that the functional $\mathcal{G}_\varepsilon$ has a minimum $v_\varepsilon$ in the class

$$K_T = \{v \in BV(\Omega): v \, > \, T\}.$$

The minimum $v_\varepsilon$ is actually of class $C^{1,\alpha}$ in $\Omega$. 

LEMMA 4.2. Let \( v_\varepsilon \) be a minimum for the functional \( G_\varepsilon \) in \( K_\varepsilon \), and let \( u_\varepsilon \) be a minimum for \( \mathcal{F}_\varepsilon \) in \( BV(\Omega) \). Suppose that

\[
T > \max \left\{ t_\delta, \sup_{\delta_0, \Omega} |\varphi| \right\}.
\]

Then either \( u_\varepsilon < v_\varepsilon \) in \( \Omega \) or \( \mathcal{F}_\varepsilon(v_\varepsilon) = \mathcal{F}_\varepsilon(u_\varepsilon) \).

PROOF. Let

\[
w = \min(u_\varepsilon, v_\varepsilon)
\]

and

\[
A = \{ x \in \Omega : v_\varepsilon(x) < u_\varepsilon(x) \}.
\]

We have

\[
\mathcal{F}_\varepsilon(w) = \mathcal{F}_\varepsilon(u_\varepsilon) + \int_A \left( \sqrt{1 + |Dv_\varepsilon|^2} - \sqrt{1 + |Du_\varepsilon|^2} \right) dx +
\]

\[
+ \int_A (\lambda_\varepsilon(x, v_\varepsilon) - \lambda_\varepsilon(x, u_\varepsilon)) dx + \int_{\partial_\varepsilon \Omega} (|w - \varphi| - |u_\varepsilon - \varphi|) dH_{n-1} + \int_{\partial_\varepsilon \Omega} \kappa_\varepsilon(w - u_\varepsilon) dH_{n-1}
\]

Recalling that for \( x \) in \( A \) we have \( u_\varepsilon > v_\varepsilon > T > t_\delta \), we get

\[
\int_A (\lambda_\varepsilon(x, v_\varepsilon) - \lambda_\varepsilon(x, u_\varepsilon)) dx < \int_A H_\varepsilon(x, t_\delta)(v_\varepsilon - u_\varepsilon) dx.
\]

On the other hand the function \( y = \max(u_\varepsilon, v_\varepsilon) \) is in \( K_\varepsilon \), and therefore \( G_\varepsilon(v_\varepsilon) < G_\varepsilon(y) \). This implies

\[
\int_A \left( \sqrt{1 + |Dv_\varepsilon|^2} - \sqrt{1 + |Du_\varepsilon|^2} \right) dx + \int_A H_\varepsilon(x, t_\delta)(v_\varepsilon - u_\varepsilon) dx < \int_{\partial_\varepsilon \Omega} \kappa_\varepsilon(y - v_\varepsilon) dH_{n-1}.
\]

Comparing with (4.9) and (4.10):

\[
\mathcal{F}_\varepsilon(w) < \mathcal{F}_\varepsilon(u_\varepsilon) + \int_{\partial_\varepsilon \Omega} (w - u_\varepsilon + y - v_\varepsilon) \kappa_\varepsilon dH_{n-1} +
\]

\[
+ \int_{\partial_\varepsilon \Omega} ((1 - \varepsilon)(y - v_\varepsilon) + |w - \varphi| - |u_\varepsilon - \varphi|) dH_{n-1} < \mathcal{F}_\varepsilon(u_\varepsilon).
\]

From the uniqueness of the minimum we get

\[
w = u_\varepsilon + c, \quad c < 0
\]
and hence either \( w = u_\varepsilon \), so that \( u_\varepsilon < v_\varepsilon \), or \( w = v_\varepsilon \), and then

\[
F_\varepsilon(v_\varepsilon) = F_\varepsilon(u_\varepsilon). \quad \text{Q.E.D.}
\]

In any case there exists a function \( u_\varepsilon \) minimizing the functional \( F_\varepsilon \), satisfying \( u_\varepsilon < v_\varepsilon \), so that an upper bound for \( v_\varepsilon \) will give a corresponding upper bound for \( u_\varepsilon \).

In a similar way we can find a lower bound for \( u_\varepsilon \) by means of the solution \( w_\varepsilon \) to the problem

\[
\int_\Omega \sqrt{1 + |Dw|^2} + \int_\Omega H_\varepsilon(x, t_\varepsilon) w \, dx + \int_{\partial \Omega} \kappa w \, dH_{n-1} - \int_{\partial \Omega} (1 - \varepsilon) w \, dH_{n-1} \to \min
\]

in the class

\[
\{ w \in BV(\Omega) : w \leq -T \}.
\]

We are then reduced to the problem of finding a uniform upper bound for \( v_\varepsilon \) (and a lower bound for \( w_\varepsilon \)). Since the arguments are perfectly symmetrical we shall consider in detail only the first problem.

4.D. In order to avoid unnecessary complications we shall omit the suffix \( \varepsilon \); we will derive an upper estimate for a function \( v(x) \), minimizing the functional

\[
G(v) = \int_\Omega \sqrt{1 + |Dv|^2} + \int_\Omega H(x) v \, dx + \int_{\partial \Omega} \kappa v \, dH_{n-1}
\]

in the class \( K_\varepsilon \); the functions \( H \) and \( \kappa \) satisfy the relations

\[
(4.11) \quad \int_B H \, dx + \int_{\partial B} \kappa \varphi B \, dH_{n-1} \geq -\int_\Omega |D\varphi_\varepsilon| + \kappa_\varepsilon \min \{|B|, |\Omega - B|\}
\]

for every set \( B \subset \Omega \);

\[
(4.12) \quad \kappa(x) \geq -\kappa_1 \quad \forall x \in \partial \Omega - L_{-1}
\]

\[
(4.13) \quad H(x) \geq -\Delta d(x) + \kappa_1 \quad \forall x \in L_{-3}
\]

where \( L_{-1} \) and \( L_{-3} \) are open sets, with \( L_{-1} \subset L_{-1} \subset L_{-3} \).

It is clear that \( H_\varepsilon(x, t_\varepsilon) \) and \( \kappa_\varepsilon \) satisfy the preceding relations uniformly for \( \varepsilon > 0 \) in a neighborhood of 0.
LEMMA 4.2. For every $v \in K_T$ we have

\[ (4.14) \quad \int_{\Omega} |v - v_\Omega| \, dx \leq 2 \mathcal{G}(v)/\alpha_0, \]

where $v_\Omega$ denotes the mean value of $v$ in $\Omega$.

PROOF. Let

\[ V_t = \{ x \in \Omega : v(x) > t \}; \]

we have from (4.11):

\[ \int_0^\infty \left\{ \int_{\Omega} H_v d\mu + \int_{\partial \Omega} \alpha_{\partial \Omega} dH_{n-1} + \int_{\partial \Omega} |Dv| \right\} dt > \alpha_0 \int \min\{ |V_t|, |\Omega - V_t| \} \, dt \]

and hence

\[ \mathcal{G}(v) > \int_{\Omega} |Dv| + \int_{\partial \Omega} H_v \, dx + \int_{\partial \Omega} \alpha_{\partial \Omega} dH_{n-1} > \alpha_0 \int \min\{ |V_t|, |\Omega - V_t| \} \, dt. \]

Let $\tau$ be such that

\[ |V_t| > |\Omega|/2 \quad \text{for} \quad t < \tau \]
\[ |V_t| < |\Omega|/2 \quad \text{for} \quad t > \tau ; \]

then

\[ \int \min\{ |V_t|, |\Omega - V_t| \} \, dt = \int_{\Omega} |v - \tau| \, dx \]

and (4.14) follows from the simple inequality

\[ \int_{\Omega} |v - v_\Omega| \, dx \leq 2 \int_{\Omega} |v - \tau| \, dx. \quad \text{Q.E.D.} \]

In particular, if $v$ minimizes $\mathcal{G}$ in $K_T$, we have the uniform estimate:

\[ (4.15) \quad \int_{\Omega} |v - v_\Omega| \, dx \leq 2 \mathcal{G}(T)/\alpha_0 < c_{zz}. \]

The next step consists in getting an estimate for the area of $v$ in compact subsets of $\Omega$. For $s > 0$ let

\[ \Omega_s = \{ x \in \Omega : d(x) > s \}. \]
LEMMA 4.3. For every $s > 0$ there exists a constant $c_{23}(s)$ such that if $v(x)$ minimizes $\mathcal{G}$ in $K_T$, we have:

\[ \int_{\Sigma_s} \sqrt{1 + |Dv|^2} \, dx < c_{23}(s). \]

PROOF. Let $g(x)$ be a smooth function in $\Omega$, with $0 < g < 1$, $g = 1$ in $\Omega_s$ and $g = 0$ near $\partial \Omega$.

Let $w = \max(0, v - v_D)$ and let

\[ h = v - gw. \]

We have $h \in K_T$ and therefore $\mathcal{G}(v) < \mathcal{G}(h)$. If we observe that $h = v$ near $\partial \Omega$, we get

\[ \int_{\Sigma_s} \left( \sqrt{1 + |Dv|^2} - \sqrt{1 + |Dh|^2} \right) \, dx < \int_{\Sigma} Hgw \, dx. \]

On the other hand

\[ \sqrt{1 + |Dv|^2} - \sqrt{1 + |Dh|^2} = \sqrt{1 + |Dw|^2} - \sqrt{1 + |D(w - gw)|^2} \]

\[ > \sqrt{1 + |Dw|^2} - \sqrt{1 + (1 - g)^2|Dw|^2 - w|Dg|} \]

and whence

\[ \int_{\Sigma_s} \sqrt{1 + |Dw|^2} \, dx < |\Omega| + \int_{\Sigma} w(|H| + |Dg|) \, dx. \]

In a similar way, if $z = \min(0, v - v_D)$ and $k = v - gz$, we get

\[ \int_{\Sigma_s} \sqrt{1 + |Dz|^2} \, dx < |\Omega| + \int_{\Sigma} z(|H| + |Dg|) \, dx. \]

Combining the last two inequalities:

\[ \int_{\Sigma_s} \sqrt{1 + |Dv|^2} \, dx < 2|\Omega| + c_{24}(s) \int_{\Sigma} (w + |z|) \, dx = 2|\Omega| + c_{24} \int_{\Sigma} |v - v_D| \, dx \]

and (4.16) follows at once from (4.15). Q.E.D.

We conclude this section with an estimate of the oscillation of $v$. 
LEMMA 4.4. For every $s > 0$ there exists a constant $c_{25}(s)$ such that

\begin{equation}
\text{osc}_x (v) < c_{25} \sqrt{1 + |Dv|^2} \, dx
\end{equation}

PROOF. Let

$$V = \{ (x, t) \in \Omega \times \mathbb{R} : t < v(x) \}.$$ 

If $B$ is a $(n+1)$-ball centered on $\partial V = \text{graph}(v)$ and contained in the set $\Omega_s \times (T, + \infty)$, we have ([20]):

$$\int_B |D\varphi| + \int_B H \varphi_r \, dx \, dt \leq \int_B |D\varphi_q| + \int_B H \varphi_q \, dx \, dt$$

for every set $Q$ coinciding with $V$ in a neighborhood of $\partial B$.

From [19] we get the estimate

$$\int_B |D\varphi| \geq \omega_n r^n - n\omega_{n+1} \sup |H| r^{n+1}$$

where $r$ is the radius of $B$.

If $n\omega_{n+1} \sup |H| r < \omega_n/2$ we have

\begin{equation}
\int_B |D\varphi| \geq \omega_n r^n/2.
\end{equation}

Let now

$$\lambda = \text{osc}_x (v);$$

if $r < s$ there are at least $[\lambda/2r]$ disjoint balls contained in $\Omega_s \times (T, + \infty)$ for which (4.18) holds. We have therefore

$$\int_{\Omega_s} \sqrt{1 + |Dv|^2} \, dx = \int_{\Omega_s \times R} |D\varphi_q| \omega_n r^n/2$$

and (4.17) follows at once. Q.E.D.

4.E. The results of the preceding section give the uniform estimate

\begin{equation}
\text{osc}_x (v) < c_{26}(s).
\end{equation}
Using the supplementary conditions (4.12) and (4.13) we shall get a bound for the supremum of \( v \) in \( \Omega \).

Let \( d_0 > 0 \) be such that the distance function \( d(x) \) is twice differentiable outside \( \Omega_{d_0} \), and let

\[
A = 1 + \sup_{\Omega - \Omega_{d_0}} \{|\Delta d| + |H|\}.
\]

The function

\[
g(s) = \frac{1}{A} \left( 1 - (A^s + \alpha)^2 \right)^{\frac{1}{2}}
\]

satisfies the equation

\[
g'' = -A(1 + g')^\frac{3}{2}
\]

in the interval \( 0 < s < (1 - \alpha)/2A = s_0 \).

If we set \( s_1 = \min(d_0, s_0) \) and

\[
z(x) = g(d(x)) - g(0)
\]

we have, for every \( x \in \Omega - \Omega_{s_1} \):

\[
\mathcal{L}(z) = -A - H(x) + \Delta g'(1 + g')^{-1}
\]

where \( \mathcal{L} \) is the Euler operator relative to the functional \( \mathcal{G} \):

\[
\mathcal{L}(z) = (1 + |Dz|^2)^{-\frac{1}{2}} \left( (1 + |Dz|^2) \Delta z - 2\alpha z z_{x_1} z_{x_2} \right) - H(x).
\]

From (4.20) it follows immediately

\[
\mathcal{L}(z) < -1
\]

so that \( z \) is a strict supersolution in the strip \( \Omega - \Omega_{s_1} \).

Let now \( L_{-1} \) and \( L_{-3} \) be as in (4.12), (4.13), and let \( L_{-2} \) be an open set such that

\[
L_{-1} \subset \bar{L}_{-1} \subset L_{-2} \subset \bar{L}_{-2} \subset L_{-3}.
\]

Let \( M(x) \) be a function of class \( C^2 \) in \( \bar{\Omega} \), such that

\[
M(x) = -1 \quad \text{in } L_{-1}
\]

\[
M(x) = 2/|x|_1 \quad \text{outside } L_{-3};
\]
let \( s_2 = \min(d_2, 2/\alpha_1) \), and for \( x \) in \( \Omega - \Omega_{s_1} \) let

\[
y(x) = M(x) - \frac{2}{\alpha_1} \left\{ 1 - \left( \alpha_1 d(x)/2 - 1 \right)^2 \right\}^{\frac{1}{4}} = M(x) + k(d(x)).
\]

If we observe that the function \( k(s) \) satisfies

\[
k' = \frac{\alpha_1}{2} (1 + k'x)^\frac{1}{2}
\]

we get easily:

\[
\mathcal{L}(y) \leq (1 + |Dy|^2)^{-\frac{1}{2}} \left\{ m_1 + m_2 k'x + \frac{\alpha_1}{2} (1 + k'x)^\frac{1}{2} + k'^2 Ad \right\} - H(x)
\]

where \( m_1 \) and \( m_2 \) depend only on the \( C^2 \) norms of \( M \) and \( d \).

Let now \( x \in L_{-2} \cap (\Omega - \Omega_{s_1}) \); from (4.13) we get

\[
\mathcal{L}(y) \leq (1 + |Dy|^2)^{-\frac{1}{2}} (m_1 + m_2 k'x) + (Ad - \alpha_1/2) (1 + k'x)^{\frac{1}{2}} (1 + |Dy|^2)^{-\frac{1}{2}} - \alpha_1/2 - \alpha_1/2 + R.
\]

As \( s \to 0^+ \), we have \( |Dy| \to +\infty \) and \( k'(1 + |Dy|^2)^{-\frac{1}{2}} \to -1 \), and therefore \( R \to 0 \). We can conclude that there exists a positive number \( \alpha_2 \) such that

\[
\mathcal{L}(y) \leq -\alpha_1/4 \quad \text{in} \quad L_{-3} \cap (\Omega - \Omega_{s_1}).
\]

In addition we have

\[
-1 < -1/d < z(x) < 0
\]

and

\[
-2/\alpha_1 < k(x) < 0
\]

whence

\[
y(x) = -1 + k(d) < -1 < z(x) \quad x \in L_{-1}
\]

\[
y(x) = 2/\alpha_1 + k(d) > 0 > z(x) \quad x \notin L_{-2}.
\]

If we set

\[
Z(x) = \min\{z(x), y(x)\}
\]

the function \( Z \) is a strict supersolution for the functional \( \mathcal{G} \) in the strip \( \Omega - \Omega_{s_2} \) \((s_2 = \min(s_1, s_3))\), coinciding with \( y \) in \( L_{-1} \) and with \( z \) outside \( L_{-2} \).
More precisely, if $\eta$ is a non-negative function with support in the strip $\Omega - \Omega_4$, we have:

$$\int \frac{D_t Z D_t \eta}{\sqrt{1 + |DZ|^2}} \, dx + \int H \eta \, dx > 0$$

the equality sign holding only for $\eta = 0$.

**Lemma 4.5.** For every $g \geq 0$, with $g = 0$ in $\Omega_4$, we have:

$$\int \frac{D_t g D_t Z(1 + |DZ|^2)^{-\frac{1}{2}}} \, dx + \int H g \, dx + \int_{\partial \Omega} g H_{n-1} \, dS > 0,$$

the equality sign holding only for $g = 0$.

**Proof.** Let $0 < \varphi < s_4$

$$\varphi(x) = \min(d(x)/\varphi, 1)$$

and let

$$\eta(x) = g(x)\varphi(x).$$

From (4.23) we get

$$\int \frac{D_t g D_t Z(1 + |DZ|^2)^{-\frac{1}{2}}} \, dx + \frac{1}{\varphi} \int_{\Omega - \Omega_4} g D_t dD_t Z(1 + |DZ|^2)^{-\frac{1}{2}} \, dx + \int \varphi H g \, dx > 0.$$  

As $\varphi \to 0$ we have

$$\frac{1}{\varphi} \int_{\Omega - \Omega_4} g D_t dD_t Z(1 + |DZ|^2)^{-\frac{1}{2}} \, dx \to \int_{\partial \Omega} g \beta \, dH_{n-1}$$

where $\beta$ satisfies

$$\begin{cases} 
\beta < -\kappa_1 & \text{in } \partial \Omega \\
\beta = -1 & \text{in } L_{n-1} \cap \partial \Omega.
\end{cases}$$

As $\beta < \kappa$ the conclusion of the lemma follows immediately passing to the limit in (4.25). Q.E.D.

It is clear that the conclusion of the lemma holds if $Z$ is replaced by $Z + \text{const.}$
PROPOSITION 4.3. Let \( v \) be a minimizing function for the functional \( \mathcal{G} \) in the class \( K_T \) and let \( p > 0 \) be such that the function \( w = Z + p \) satisfies

\[
\begin{align*}
& w > T \quad \text{in } \Omega - \Omega_s, \\
& w > v \quad \text{in } \partial \Omega_s, \; s < s_4.
\end{align*}
\]

Then

\[
w > v \quad \text{in } \Omega - \Omega_s.
\]

PROOF. Let

\[
g = \begin{cases} v - \min(v, w) & \text{in } \Omega - \Omega_s, \\ 0 & \text{in } \Omega_s. \end{cases}
\]

The function \( g \) is Lipschitz-continuous and non-negative in \( \Omega \); we want to prove that \( g = 0 \).

Suppose this is not true, and let

\[
m(t) = \mathcal{G}(\min(v, w) + tg).
\]

We have

\[
m'(0) = \int_\Omega D_s v D_t g (1 + |Dw|^2)^{\frac{1}{2}} \, dx + \int_{\partial \Omega} Hg \, dx + \int_{\partial \Omega} \mathcal{K} d\mathcal{H}_{n-1} > 0
\]

and from the convexity of \( \mathcal{G} \):

\[
\mathcal{G}(v) = m(1) > m(0) = \mathcal{G}(\min(v, w))
\]

contradicting the minimality of \( v \). Q.E.D.

4.F. From Proposition 4.3 we get immediately the inequality

\[
(4.27) \quad \sup_{\Omega} v(x) < \sup_{\partial \Omega} v(x) + c_{\mathcal{K}}, \quad s < s_4.
\]

In view of (4.19) we need only an estimate for the quantity

\[
m_s = \inf_{\partial \Omega} v(x)
\]

As in ch. 2 we discuss first the case where

\[
(4.28) \quad \int_\Omega H \, dx + \int_{\partial \Omega} \mathcal{K} d\mathcal{H}_{n-1} > h_s > 0
\]
(we remark that if (4.28) holds for $\varepsilon = 0$, it holds uniformly for $0 < \varepsilon < \frac{1}{2}$).

Let

$$B_s = \{ x \in \Omega : v(x) < m_s \}$$

and let

$$v_s = \max(v, m_s).$$

We have

$$G(v_s) = G(v) - \int_{B_s} \sqrt{1 + |Dv|^2} \, dx + |B_s| + \int_{\partial B_s} H w_s \, \nu_x + \int_{\partial \Omega} \delta w \, dH_{n-1}$$

where

$$w_s = \max(m_s - v, 0).$$

Using lemma 4.1 we get easily:

$$G(v_s) \leq G(v) + |B_s|[(1 + m_s - T)[c_{2a}(\Omega) + \sup_{\partial \Omega} |H|]] =$$

$$= G(v) + |B_s|[(1 + c_{2a}(m_s - T)].$$

On the other hand we deduce from (4.28):

$$G(v_s - m_s + T) = G(v_s) - (m_s - T)\{ \int_{\partial \Omega} H \, dx + \int_{\partial \Omega} \delta dH_{n-1} \} < G(v_s) - h_0(m_s - T)$$

and hence

$$G(v_s - m_s + T) < G(v) + |B_s| - (m_s - T)(h_0 - c_{2a}|B_s|).$$

Since $v_s - m_s + T \geq T$, we have $G(v) < G(v_s - m_s + T)$ and therefore

$$m_s < T + 2|\Omega|/h_0$$

provided $s$ is so small that

$$c_{2a}|B_s| < c_{2a}|\Omega - \Omega_s| < h_0/2.$$

In conclusion, if $s$ is small enough we have the inequality

$$(4.29) \quad \inf_{\Omega} v(x) < c_{2a},$$

which eventually, together with (4.19) and (4.27), gives the required bound.
for the function \( v(x) \):

\[
(4.30) \quad \sup_{\partial} v(x) < c_{39}.
\]

### 4.G. It remains the case when

\[
(4.31) \quad \int_{\partial} H(x, t_0) \, dx + \int_{\partial} \kappa dH_{\gamma_{t_0}} + \int_{\partial} dH_{\kappa_{t_0}} = 0.
\]

This is the typical situation when the curvature function \( H \) does not depend on \( t \) and \( \partial_1 \Omega = \emptyset \); actually (4.31) becomes a necessary condition in this case, as one can easily see from (4.2') and (4.2") (or else integrating equation (0.2) in \( \Omega \) with the boundary conditions (0.3)).

As in 2.F, Lemma 2.5, we deduce from (4.11) and (4.31) the inequality

\[
(4.32) \quad \left| \int_{\partial} H \, dx + \int_{\partial} \kappa dH_{\gamma_{t_0}} \right| < \int_{\partial} |D\varphi| - \chi_0 \min \{|B|, |\Omega - B|\}
\]

for every set \( B \subset \Omega \), where

\[
\mathcal{R}(x) = \begin{cases} 
\kappa(x) & x \in \partial_2 \Omega \\
1 & x \in \partial_1 \Omega
\end{cases}
\]

It follows from (4.32) and Proposition 4.1 (remember that \( \partial_1 \Omega \) is open in \( \partial \Omega \)) that the new function \( \mathcal{R} \) satisfies the supplementary condition (4.5).

Let now \( \varepsilon > 0 \) and let \( v_\varepsilon \) be a minimizing function for the functional \( \mathcal{G}_\varepsilon \) in \( K_0 \). We have as above the estimates

\[
(4.33) \quad \text{osc}_{\partial \varepsilon} (v_\varepsilon) < c_{38}(\varepsilon)
\]

and

\[
(4.34) \quad \sup_{\partial} v_\varepsilon < \sup_{\partial \varepsilon} v_\varepsilon + c_{27}
\]

with \( c_{38} \) and \( c_{27} \) independent of \( \varepsilon \).

On the other hand from (4.31) we get \( \mathcal{G}_\varepsilon(v) = \mathcal{G}_\varepsilon(v + \text{const}) \), and hence \( v_\varepsilon \) minimizes \( \mathcal{G}_\varepsilon \) in \( BV(\Omega) \). From (4.32) and the supplementary condition (4.5) we conclude with the same argument as before

\[
(4.35) \quad \inf_{\Omega} v_\varepsilon > \inf_{\partial \varepsilon} v_\varepsilon - c_{31}
\]

which, together with (4.33) and (4.34) gives

\[
\text{osc}_{\partial} (v_\varepsilon) < c_{26}.
\]
Adding possibly a constant to the function \( v_\varepsilon \) we can suppose that 
\[ \inf_\Omega v_\varepsilon = T, \] 
getting the required bound (4.30).

4.H. The estimate (4.30) and the lemma 4.2 give an \textit{a-priori} bound for 
the supremum of the function \( u_\varepsilon \), minimizing the functional \( \mathcal{F}_\varepsilon \). This 
supremum is actually independent of \( \varepsilon \).

In a similar way one can show that \( u_\varepsilon \) is bounded from below in \( \Omega \), so 
that we have the estimate

\begin{equation}
\sup_\Omega |u_\varepsilon(x)| < c_{23}.
\end{equation}

Since

\[ \mathcal{F}_\varepsilon(u_\varepsilon) < \mathcal{F}_\varepsilon(0) = |\Omega| + \int_{\partial_1 \Omega} |\varphi| dH_{n-1} \]

we have from (4.36) the inequality

\begin{equation}
\int_{\partial_1 \Omega} \sqrt{1 + |Du_\varepsilon|^2} < c_{34}
\end{equation}

where we have set, as usual, \( u = f \) in \( \Omega_1 - \Omega \).

Let now \( \varepsilon_i \) be a sequence converging to zero; from \( \{u_\varepsilon_i\} \) we can extract 
a subsequence converging in \( L_1(\Omega_1) \) to a function \( u(x) \). It is easily seen that \( u \) 
gives a minimum for the functional \( \mathcal{F} \). We have in conclusion:

**Theorem 4.1.** With the assumptions of section 4.A the functional

\[ \mathcal{F}(u) = \int_\Omega \sqrt{1 + |Du|^2} + \int_\Omega \lambda(x, u) \, dx + \int_{\partial \Omega} |u - \varphi| dH_{n-1} + \int_{\partial \Omega} \kappa u \, dH_{n-1} \]

has a minimum in \( BV(\Omega) \).

It is clear that the results of ch. 3 apply to this case; in particular every 
minimizing function has Hölder-continuous second derivatives in \( \Omega \).
