# ENDS OF GROUPS AND BASELESS SUBGROUPS OF WREATH PRODUCTS 

C. H. Houghton

## Introduction

In this paper we investigate the relationship between Specker's theory [4] of ends of groups and Hartley's results [2] on baseless subgroups of wreath products. The wreath product $W=A W r B$ of groups $A$ and $B$ is the split extension of the group $K=A^{B}$ of functions from $B$ to $A$, by $B$, with $f^{b}(x)=f\left(x b^{-1}\right)$, for $f \in A^{B}, b, x \in B$. We shall assume throughout that $A$ and $B$ are non-trivial. Let $\alpha$ be an infinite cardinal and, for $f \in K$, let supp $(f)$ denote the support of $f$. We define $K_{\alpha}$ to consist of those $f \in K$ with $|\operatorname{supp}(f)|<\alpha$ and let $W_{\alpha}=B K_{\alpha} \leqq W$. We note that in the case $\alpha=\boldsymbol{N}_{0}, K_{\alpha}$ consists of those functions with finite support and $W_{\alpha}$ is the restricted wreath product $A w r B$ of $A$ and $B$.

Hartley [2] investigates baseless subgroups of $W_{\alpha}$, that is, subgroups which have trivial intersection with the base group $K_{\alpha}$. He gives conditions for baseless subgroups of $W_{\alpha}$ to be conjugate to subgroups of $B$ and conditions for the existence of baseless subgroups which are maximal in some class of subgroups of $W_{\alpha}$. He applies these results to construct locally finite groups with certain given sets of locally finite $p$-groups as Sylow p-subgroups. Our aim is to establish a connection between Hartley's results and the theory of ends, which we now consider.

For a group $G$, we define $Q_{\alpha}(G)$ to consist of those $S \subseteq G$ such that $\left|S g \cap S^{\prime}\right|<\alpha$, for all $g \in G$, where $S^{\prime}=G \backslash S$. The set of $\alpha$-ends of $G$ consists of the ultrafilters of sets $S$ in $Q_{\alpha}(G)$ with $|S| \geqq \alpha$. We denote the number of $\alpha$-ends of $G$ by $e_{\alpha}(G)$; in the case $\alpha=\aleph_{0}$, we omit mention of the cardinal. From now on we assume $|G| \geqq \alpha$, which is equivalent to the condition $e_{\alpha}(G)>0$. Specker [4] shows that $e_{\alpha}(G)=1,2$, or is infinite and that $e_{\alpha}(G)=2$ if and only if $\alpha=\boldsymbol{\kappa}_{0}$ and $G$ is infinite cyclic by finite. We note that $e_{\alpha}(G)=1$ if and only if, for $S \subseteq G$, the condition $\left|S g \cap S^{\prime}\right|<\alpha$, for all $g \in G$, implies $|S|<\alpha$ or $\left|S^{\prime}\right|<\alpha$.

The theory of ends of groups, with $\alpha=\aleph_{0}$, has been studied extensively (see Cohen [1], Stallings [5]); in particular, finitely generated groups with more than one end have been characterised. Various sufficient con-
ditions for $G$ to have 1 end are known and some may be extended to the case of a general cardinal $\alpha$. We do not pursue this point, as the results in the case $\alpha=\boldsymbol{\aleph}_{0}$ are far from complete. We require the following result.

Theorem (1): (Specker [4, p. 173 (a)]). If either $|G|=\alpha>\aleph_{0}$ or $|G|=\alpha=\aleph_{0}$ and $G$ is locally finite, then $e_{\alpha}(G)$ is infinite.

## Baseless subgroups and ends

Let $L$ be a baseless subgroup of $W=A W r B$. Then, for a unique $C \leqq B, L A^{B}=C A^{B}$. Hartley shows [2, Lemma 3.2. (i)] that there is an element $g \in A^{B}$ such that $L=C^{g}$. It follows that the baseless subgroups of $W_{\alpha}$ are all the subgroups of $W$ of the form $C^{g}$ with $C \leqq B, g \in A^{B}$ and $C^{g} \leqq W_{\alpha}$. Throughout this section, let $S^{\prime}=B \backslash S$, for $S \subseteq B$.

Lemma (2): Suppose $C \leqq B$ and $g \in A^{B}$. Let $g(B)=\left\{a_{i}: i \in I\right\}$ and $B_{i}=\left\{b \in B: g(b)=a_{i}\right\}$. Then
(i) $C^{g} \leqq W_{\alpha}$ if and only if

$$
\left|\bigcup_{i \in I} B_{i} c \cap B_{i}^{\prime}\right|<\alpha
$$

for all $c \in C$,
(ii) if $|C| \geqq \alpha, C^{g}$ is conjugate to $C$ in $W_{\alpha}$ if and only if there is a subset $J$ of $I$ and a partition $\left\{D_{j}: j \in J\right\}$ of $B$ with $D_{j} C=D_{j}$ such that

$$
\left|\bigcup_{j \in J} D_{j} \cap B_{j}^{\prime}\right|<\alpha
$$

Proof: (i) If $c \in C, c^{g}=g^{-1} c g=c\left(g^{-1}\right)^{c} g$ and so $c^{g} \in W_{\alpha}$ if and only if $\mid \operatorname{supp}\left(\left(g^{-1}\right)^{c} g \mid<\alpha\right.$. Now $\left(\left(g^{-1}\right)^{c} g\right)(x)=\left(g\left(x c^{-1}\right)\right)^{-1} g(x)$, so

$$
\operatorname{supp}\left(\left(g^{-1}\right)^{c} g\right)=\bigcup_{i \in I} B_{i} c \cap B_{i}^{\prime}
$$

Thus $C^{g} \leqq W_{\alpha}$ if and only if

$$
\left|\bigcup_{i \in I} B_{i} c \cap B_{i}^{\prime}\right|<\alpha, \text { for all } c \in C .
$$

(ii) Suppose $C^{g}=C^{h}$ with $h \in K_{\alpha}$. Then $z=g h^{-1}$ is in the centraliser of $C$ and hence is constant on each left coset $b C$ of $C$ in $B$. Since $\left|\operatorname{supp} \quad\left(z^{-1} g\right)\right|=|\operatorname{supp}(h)|<\alpha \quad$ and $\quad|C| \geqq \alpha, \quad z(B) \subseteq g(B)$. Let $J=\left\{i \in I: a_{i} \in z(B)\right\}$ and let $D_{j}=\left\{b \in B: z(b)=a_{j}\right\}$, for $j \in J$. Then $\left\{D_{j}: j \in J\right\}$ is a partition of $B$ with $D_{j} C=D_{j}$ and

$$
\bigcup_{j \in J} D_{j} \cap B_{j}^{\prime}=\operatorname{supp}\left(z^{-1} g\right)=\operatorname{supp}(h)
$$

$$
\left|\bigcup_{j \in J} D_{j} \cap B_{j}^{\prime}\right|<\alpha
$$

Conversely, suppose the given condition is satisfied and define $z \in A^{B}$ by $z\left(D_{j}\right)=\left(g\left(B_{j}\right)\right)^{-1}$. Then $C^{g}=C^{z g}$ and

$$
\operatorname{supp}(z g)=\bigcup_{j \in J} D_{j} \cap B_{j}^{\prime}
$$

so $\mid$ supp $(z g) \mid<\alpha$.
Theorem (3): Suppose $L$ is a baseless subgroup of $W_{\alpha}$ with $L A^{B}=C A^{B}$, $C \leqq B$. If $e_{\alpha}(C)=1$, then $L$ is conjugate to $C$ in $W_{\alpha}$.

Proof: We have $L=C^{g}$ where the partition associated with $g$ satisfies

$$
\left|\bigcup_{i \in I} B_{i} c \cap B_{i}^{\prime}\right|<\alpha
$$

for $c \in C$. For $i \in I, b \in B$ we have, for all $c \in C$,
$B_{i} c \cap B_{i}^{\prime} \supseteq\left(b C \cap B_{i}\right) c \cap\left(b C \cap B_{i}^{\prime}\right)=b\left(\left(C \cap b^{-1} B_{i}\right) c \cap\left(C \cap b^{-1} B_{i}^{\prime}\right)\right)$
and hence $\left|\left(C \cap b^{-1} B_{i}\right) c \cap\left(C \backslash\left(C \cap b^{-1} B_{i}\right)\right)\right|<\alpha$. Since $e_{\alpha}(C)=1$, $\left|C \cap b^{-1} B_{i}\right|<\alpha$ or $\left|C \cap b^{-1} B_{i}^{\prime}\right|<\alpha$ and so $\left|b C \cap B_{i}\right|<\alpha$ or $\left|b C \cap B_{i}^{\prime}\right|<\alpha$. Let $M=\left\{(b C, i): 0<\left|b C \cap B_{i}\right|<\alpha\right\}$.

We first suppose $|C|>\alpha$ and take $N \subseteq M$, with $|N| \leqq \alpha$. Then

$$
\left|\bigcup_{(b c, i) \in N}\left(b C \cap B_{i}\right)^{-1}\left(b C \cap B_{i}\right)\right| \leqq \alpha,
$$

so there is an element $c \in C$ such that, for $(b C, i) \in N$, $c \notin\left(b C \cap B_{i}\right)^{-1}\left(b C \cap B_{i}\right)$ and $\left(b C \cap B_{i}\right) c \subseteq B_{i}^{\prime}$. Then

$$
\begin{aligned}
\left|\bigcup_{(b C, i) \in N} b C \cap B_{i}\right| & =\left|\bigcup_{(b C, i) \in N}\left(b C \cap B_{i}\right) c\right| \\
& =\left|\bigcup_{(b C, i) \in N}\left(b C \cap B_{i}\right) c \cap B_{i}^{\prime}\right| \\
& \leqq\left|\bigcup_{i \in I} B_{i} c \cap B_{i}^{\prime}\right|<\alpha .
\end{aligned}
$$

So $|N|<\alpha$ and we deduce that $|M|<\alpha$ and

$$
\left|\bigcup_{(b C, i) \in M} b C \cap B_{i}\right|<\alpha
$$

In the other case, $|C|=\alpha$. Since we are assuming $e_{\alpha}(C)=1$, Theorem 1 implies that $\alpha=\kappa_{0}$ and $C$ is not locally finite. Let $D=\left\langle d_{1}, \cdots, d_{n}\right\rangle$ be a finitely generated infinite subgroup of $C$. Since, for $j=1, \cdots, n$,

$$
\bigcup_{i \in I} B_{i} d_{j} \cap B_{i}^{\prime}
$$

is finite, almost all $B_{i}$ are fixed under right multiplication by $d_{1}, \cdots, d_{n}$. So $H=\left\{i: B_{i} \neq B_{i} D\right\}$ is finite. If $(b C, i) \in M$ then $b C \cap B_{i}$ is finite and non-empty. Thus $b C \cap B_{i} \neq\left(b C \cap B_{i}\right) D=b C \cap B_{i} D$, so $B_{i} \neq B_{i} D$
and $i \in H$. Also, for some $d_{j},\left(b C \cap B_{i}\right) d_{j} \cap B_{i}^{\prime} \neq \emptyset$ so, for some $c \in C$, $b c \in B_{i} \cap B_{i}^{\prime} d_{j}^{-1}$ and $b \in\left(B_{i} \cap B_{i}^{\prime} d_{j}^{-1}\right) C$. Thus if $(b C, i) \in M$, then $i \in H$ and $b C \subseteq F C$, where $F$ is the finite set

$$
\bigcup_{j=1}^{n}\left(\bigcup_{i \in I} B_{i} d_{j} \cap B_{i}^{\prime}\right) d_{j}^{-1} .
$$

So $M$ is finite and hence

$$
\bigcup_{(b C, i) \in M} b C \cap B_{i}
$$

is also finite.
In each case, we now have

$$
\left|\bigcup_{(b c, i) \in M} b C \cap B_{i}\right|<\alpha .
$$

Furthermore,

$$
|C| \geqq \alpha \text { and } b C=\bigcup_{i \in I} b C \cap B_{i}
$$

Thus, for $b \in B,\left|b C \cap B_{i}\right| \geqq \alpha$ for some $i$ and then $\left|b C \cap B_{j}\right|<\alpha$ for $\neq i$. For $i \in I$, let $T_{i}=\left\{b C:\left|b C \cap B_{i}\right| \geqq \alpha\right\}$ and let

$$
D_{i}=\bigcup_{b C \in T_{i}} b C .
$$

Put $J=\left\{i \in I: D_{i} \neq \emptyset\right\}$. Then $\left\{D_{j}: j \in J\right\}$ is a partition of $B$ with $D_{j}=D_{j} C$. For $j \in J$,

$$
D_{j} \cap B_{j}^{\prime} \subseteq \bigcup_{(b C, i) \in M} b C \cap B_{i}
$$

so

$$
\left|\bigcup_{j \in J} D_{j} \cap B_{j}^{\prime}\right| \leqq\left|\bigcup_{(b C, i) \in M} b C \cap B_{i}\right|<\alpha
$$

Then Lemma 2 (ii) implies $L$ is conjugate to $C$ in $W_{\alpha}$.
Theorem 1 describes a class of groups $C$ with $e_{\alpha}(C)$ infinite. We now consider these groups in more detail.

Lemma (4): Suppose $|C|=\alpha>\boldsymbol{\aleph}_{0}$ or $|C|=\alpha=\boldsymbol{\aleph}_{0}$ and $C$ is locally finite. Then there is a partition $\left\{C_{1}, C_{2}\right\}$ of $C$ such that $\left|C_{1}\right|=\left|C_{2}\right|=\alpha$ and $\left|s C_{1} t \cap C_{2}\right|<\alpha$, for all $s, t \in C$.

Proof: Consider $\alpha$ as an ordinal equivalent to none of its predecessors. Under the conditions of the theorem,

$$
C=\bigcup_{\lambda<\alpha} H_{\lambda}
$$

for some system of subgroups such that $\left|H_{\lambda}\right|<\alpha$ and $H_{\lambda}<H_{\mu}$ if $\lambda<\mu$.

Let

$$
C_{1}=\bigcup_{\lambda<\alpha} H_{2 \lambda+1} \mid H_{2 \lambda} .
$$

Then

$$
C_{2}=C\left|C_{1}=H_{0} \cup \bigcup_{\lambda<\alpha} H_{2 \lambda+2}\right| H_{2 \lambda+1}
$$

and $\left|C_{1}\right|=\left|C_{2}\right|=\alpha$. Suppose $s, t \in C$. For some ordinal $\mu<\alpha$, we have $s, t \in H_{\lambda}$, for $\lambda \geqq \mu$, and so $s H_{\lambda} t=H_{\lambda}$ and $s\left(H_{\lambda+1} \backslash H_{\lambda}\right) t=H_{\lambda+1} \backslash H_{\lambda}$. Thus $s C_{1} t \cap C_{2} \subseteq s H_{\mu} t$ and $\left|s C_{1} t \cap C_{2}\right|<\alpha$.
A refinement of this argument gives a proof of Theorem 1. For a positive integer $n$,

$$
C_{i}=\bigcup_{\lambda<x} H_{n \lambda+i} \mid H_{n \lambda+i-1}
$$

is in $Q_{\alpha}(C)$ and $\left\{C_{1}, \cdots, C_{n-1}, C_{n} \cup H_{0}\right\}$ is a partition of $C$. Thus the number of $\alpha$-ends of $C$ is unbounded.

Suppose $e_{\alpha}(C)=2$. Then $\alpha=\boldsymbol{\kappa}_{0}$ and $C$ has an infinite cyclic normal subgroup $E=\langle e\rangle$ of finite index. The centraliser $H$ of $E$ in $C$ has index 1 or 2 and so $C=H \cup H d=E(F \cup F d)$, where $d=1$ or $d \in C \backslash H$ and the finite set $F$ is a set of coset representatives for $E$ in $H$. Let $P=$ $\left\{e^{i}: i>0\right\}, \quad C_{1}=P(F \cup F d)$ and $C_{2}=C \backslash C_{1}$. For $s \in H, t \in C$, $s(F \cup F d) t$ is a set of coset representatives for $E$ in $C$ and $s C_{1} t=$ $P s(F \cup F d) t=P\left\{e^{i(f)} f: f \in F \cup F d\right\}$, for some finite set of integers $\{i(f)\}$. Then $s C_{1} t \cap C_{2}$ is finite, and similarly $s C_{2} t \cap C_{1}$ is finite, for $s \in H$, $t \in C$. Thus we have proved the following result.

Lemma (5): Suppose $C$ has 2 ends. Then there is a partition $\left\{C_{1}, C_{2}\right\}$ of $C$, with $C_{1} \in Q(C)$, such that the sets $\left\{c \in C_{2}: c C_{1} \cap C_{2}\right.$ is finite $\}$ and $\left\{c \in C_{1}: c C_{2} \cap C_{1}\right.$ is finite $\}$ are infinite.

Once again we consider $C$ as a subgroup of $B$ in $W_{\alpha}$, but now assuming $e_{\alpha}(C)>1$. We recall that this implies that either $e_{\alpha}(C)$ is infinite or $\alpha=$ $火_{0}$ and $e_{\alpha}(C)=e(C)=2$.

Theorem (6): Suppose $C \leqq B$ with $e_{\alpha}(C)>1$. Then there is a baseless subgroup $L$ of $W_{\alpha}$ satisfying the following conditions:
(i) $L A^{B}=C A^{B}$,
(ii) $L$ is not conjugate to $C$ in $W_{\alpha}$,
(iii) if $M$ is a baseless subgroup of $W_{\alpha}$ with $M>L$ then $C=N_{D}(C)$ where $M A^{B}=D A^{B}$ with $D \leqq B$. Furthermore, if either $|C|=\alpha>\boldsymbol{\aleph}_{0}$ or otherwise $|C|=\alpha=\aleph_{0}$ and $C$ is locally finite or has 2 ends, then the assumptions of (iii) imply the following stronger result:
(iv) $\left|C \cap u C v^{-1}\right|<\alpha$ for all $u, v \in D \backslash C$.

Proof: Since $e_{\alpha}(C)>1$, there is a partition $\left\{C_{1}, C_{2}\right\}$ of $C$ with $\left|C_{i}\right| \geqq \alpha$ and $\left|C_{1} c \cap C_{2}\right|<\alpha$, for all $c \in C$. Then $\left|C_{2} c \cap C_{1}\right|=\mid C_{2} \cap$ $C_{1} c^{-1} \mid<\alpha$, for all $c \in C$. Take $a \in A, a \neq 1$, and define $g \in A^{B}$ by $g\left(C_{1}\right)$ $=a, g\left(C_{1}^{\prime}\right)=1$, where $C_{1}^{\prime}$ denotes $B \backslash C_{1}$. For $c \in C, \mid\left(C_{1} c \cap C_{1}^{\prime}\right) \cup$ $\left(C_{1}^{\prime} c \cap C_{1}\right)\left|=\left|\left(C_{1} c \cap C_{2}\right) \cup\left(C_{2} c \cap C_{1}\right)\right|<\alpha\right.$, so Lemma 2(i) implies $C^{g} \leqq W_{\alpha}$. Let $\left\{D_{1}, D_{2}\right\}$ be a partition of $B$ with $D_{i} C=D_{i}$ and suppose $C \subseteq D_{1}$ (here we allow $D_{2}=\emptyset$ ). Then $D_{1} \cap C_{1}^{\prime} \supseteq C_{2}$ and $D_{1} \cap C_{1}$ $=C_{1}$ so, from Lemma 2 (ii), $C^{g}$ is not conjugate to $C$ in $W_{\alpha}$.
Under the assumptions of (iii) we have $C^{g} \leqq D^{h} \leqq W_{\alpha}$ for some $h \in A^{B}$. Then $C^{g}=C^{h}$ so $\mathrm{hg}^{-1}$ centralises $C$ and the parts of the partition of $B$ corresponding to $\mathrm{hg}^{-1}$ consist of unions of left cosets $b C$. Suppose $h g^{-1}(C)=a_{1}$ and so $h\left(C_{1}\right)=a_{1} a, h\left(C_{2}\right)=a_{1}$, and $h(b)=h g^{-1}(b)$ for $b \notin C$. Let $B_{1}=\left\{b: h(b)=a_{1} a\right\}, B_{2}=\left\{b: h(b)=a_{1}\right\}$. Then

$$
B_{1}=C_{1} \cup \bigcup_{b C \in T_{1}} b C, B_{2}=C_{2} \cup \bigcup_{b C \in T_{2}} b C,
$$

where $T_{1}, T_{2}$ are disjoint sets of cosets distinct from $C$. From Lemma 2(i), $\left|B_{i} d \cap B_{1}^{\prime}\right|<\alpha$, for $d \in D$ and $i=1$, 2. If $d \in N_{D}(C) \backslash C$, then $\left|C_{i} d \cap d C\right| \geqq \alpha$ so $d C \cap B_{1} \neq \emptyset \neq d C \cap B_{2}$ and $d C \in T_{1} \cap T_{2}=\emptyset$. Thus $N_{D}(C)=C$.
We now suppose that either $|C|=\alpha>\kappa_{0}$ or otherwise $|C|=\alpha=\kappa_{0}$ and $C$ is locally finite or has 2 ends. We can then assume that the partition $\left\{C_{1}, C_{2}\right\}$ has been chosen as described in Lemma 4 or 5 . Given $u, v \in D \backslash C$, we have $\left|C_{i} u \cap B_{i}^{\prime}\right|<\alpha,\left|C_{i} v \cap B_{i}^{\prime}\right|<\alpha$. Thus for some $G_{i} \subseteq C_{i}$ with $\left|C_{i} \backslash G_{i}\right|<\alpha$, we have $G_{i} u \cup G_{i} v \subseteq B_{i}$. Then

$$
G_{i} u \cup G_{i} v \subseteq \bigcup_{b C \in T_{i}} b C .
$$

Thus, for $c_{1} \in G_{1}, c_{2} \in G_{2}, c_{1} u C \neq c_{2} v C$ and $c_{1} v C \neq c_{2} u C$ and so $c_{1}^{-1} c_{2}, c_{2}^{-1} c_{1} \notin u C^{-1}$. From Lemmas 4 and 5 , since $\left|C_{1} \backslash G_{1}\right|<\alpha$, we may choose $c_{1} \in G_{1}$ such that $\left|c_{1} C_{2} \cap C_{1}\right|<\alpha$ and hence $\mid c_{1}^{-1} C_{1} \cap$ $C_{2} \mid<\alpha$. Now $\left\{c_{2} \in C_{2}: c_{2} \notin u C v^{-1}\right\} \supseteq c_{1}^{-1} G_{2} \cap C_{2}$ so $C_{2} \cap u C v^{-1} \subseteq$ $C_{2} \cap c_{1}^{-1}\left(C \backslash G_{2}\right) \subseteq\left(C_{2} \cap c_{1}^{-1} C_{1}\right) \cup c_{1}^{-1}\left(C_{2} \backslash G_{2}\right)$ and hence $\mid C_{2} \cap$ $u C v^{-1} \mid<\alpha$. Similarly, $\left|C_{1} \cap u C v^{-1}\right|<\alpha$ and so $\left|C \cap u C v^{-1}\right|<\alpha$.
We note a consequence of Theorems 3 and 6. This generalises a result in [3] that if $A^{(B)}$ is the group of functions from $B$ to $A$ with finite support and $B$ acts as in the wreath product, then the first cohomology set $H^{1}\left(B, A^{(B)}\right)$ is trivial if and only if $B$ has 1 end. However $H^{1}\left(B, A^{(B)}\right)$ is precisely the set of conjugacy classes of complements of the base group $A^{(B)}$ in $A$ wr $B=W_{\times_{0}}$.
Corollary (7): Suppose $C \leqq B$ with $|C| \geqq \alpha$. Every baseless subgroup $L$ of $W_{\alpha}$ such that $L A^{B}=C A^{B}$ is conjugate to $C$ in $W_{\alpha}$ if and only if $e_{\alpha}(C)=1$.

For certain subgroups $C$ of $B$, Theorem 6 gives sufficient conditions for the existence of baseless subgroups $L$, with $L A^{B}=C A^{B}$, which are maximal in certain classes. Hartley's Theorem B, the first part of Theorem A and the second part of Theorem D [2] may be deduced. Using Corollary 7, the other parts of his Theorems A and D lead to new sufficient conditions for a group to have 1 end. Thus, unless they are infinite cyclic by finite, radical groups with non-periodic Hirsch-Plotkin radical have 1 end and so also do uncountable locally finite groups satisfying the normaliser condition. In this connection we mention the conjecture that uncountable locally finite groups have 1 end.

I would like to thank Dr. Hartley for sending me a preprint of [2].
