Abstract. Let \( p \) be an odd prime and let \( X \) denote the projective limit of the \( p \)-parts of the ideal class groups of the fields in the cyclotomic \( \mathbb{Z}_p \)-extension of a real quadratic number field \( F \). We present a method to compute the structure of \( X \). As an illustration of the method we compute \( X \) for \( p = 3 \) and all real quadratic fields \( \mathbb{Q}(\sqrt{f}) \) of conductor \( f < 10000 \) and \( f \equiv 1 \pmod{3} \). For all fields we find that \( X \) is finite. In other words, Iwasawa’s \( \lambda \)-invariant is zero in these cases, which confirms a conjecture of Greenberg’s.

1. Introduction

Let \( F \) be a number field and let \( p \) be an odd prime. Let

\[ F = F_0 \subset F_1 \subset F_2 \subset \cdots \]

denote the cyclotomic \( \mathbb{Z}_p \)-extension of \( F \). In other words, \( F_n = F \mathbb{Q}_n \) where \( \mathbb{Q}_n \) is the unique subfield of degree \( p^n \) of the field of \( p^{n+1} \)th roots of unity \( \mathbb{Q}(\zeta_{p^{n+1}}) \).

We let \( F_{\infty} = \bigcup_n F_n \).

The \( p \)-parts \( A_n \) of the class groups of the rings of integers of the fields \( F_n \) form a projective system

\[ A_0 \leftarrow N A_1 \leftarrow N A_2 \leftarrow N \cdots , \]

where \( N \) denotes the norm map. By K. Iwasawa’s theorem [12], there exist three integers \( \mu, \lambda, \nu \in \mathbb{Z} \), which depend on the number field \( F \) and the prime \( p \), such that

\[ \# A_n = p^{\mu p^n + \lambda n + \nu} \quad \text{for } n \text{ sufficiently large}. \]

For abelian number fields \( F \), the \( \mu \)-invariant is zero by the Ferrero–Washington theorem [12]. Moreover, the \( \mathbb{Q}_p \)-vector space

\[ V = \left( \lim_{\longrightarrow} A_n \right) \otimes \mathbb{Q}_p \]
has finite dimension $\lambda$.

If $F$ is a complex abelian field, the Main Conjecture [7] implies that the characteristic polynomial of a topological generator of $\text{Gal}(F_\infty/F)$ acting on $V$ is closely related to the $p$-adic $L$-functions $L_p(s, \omega \chi^{-1})$ associated to the characters $\chi$ of $\text{Gal}(F/\mathbb{Q})$. Here $\omega$ denotes the Teichmüller character.

When $\chi$ is an odd character, the character $\omega \chi^{-1}$ is even and the $p$-adic $L$-function $L_p(s, \omega \chi^{-1})$ is related to the $\chi^{-1}$-eigenspace of $V$. When $\chi$ is even however, the $p$-adic $L$-function is identically zero [12]. One expects that the corresponding eigenspace is trivial in this case. In other words, Iwasawa's $\lambda$-invariant should be zero for real abelian number fields $F$. This means that the projective limit $\lim_n A_n$ is finite. Equivalently, the sequence of class groups $A_0, A_1, A_2, \ldots$, stabilizes, i.e., there is an index $n_0$ such that the norm map $N : A_n \rightarrow A_{n_0}$ is an isomorphism for all $n \geq n_0$.

In his thesis [4], R. Greenberg has studied this question. He gave a sufficient criterion for $\lambda$ to be zero. Using his criterion the $\lambda$-invariant has been shown to be zero in a handful of examples [1, 6]. In this paper we present an efficient algorithm to compute the groups $A_n$ in the cyclotomic $\mathbb{Z}_p$-extension of an abelian number field. The method is based on properties of cyclotomic units and exploits the fact that certain group rings are Gorenstein rings. The algorithm not only enables us to verify in any given case that $\lambda = 0$, but it also gives the structure of $\lim_n A_n$ as a Galois module. This is a consequence of our Proposition 2.6 which says that, when $\lambda = 0$, the group of units modulo cyclotomic units becomes actually isomorphic to $A_n$ when $n$ is sufficiently large.

Although our method applies in greater generality, we restrict our attention to the simplest non-trivial case: $F$ is a real quadratic field and $p = 3$. The algorithm is inspired by the one used in [8]. As an illustration of the method we have computed the groups $A_n$ for the fields $\mathbb{Q}(\sqrt{f})$ of conductor $f < 10000$ with $f \equiv 1 \pmod{3}$. We know of only one non-trivial case where the structure of the groups $A_n$ had been computed previously: for $\mathbb{Q}(\sqrt{257})$ and $p = 3$, Greenberg [5] has shown that $A_n \cong \mathbb{Z}/3\mathbb{Z}$ for all $n$. It is not difficult to extend our computations much further.

For the case $f \equiv 1 \pmod{3}$ see the papers by T. Fukuda, K. Komatsu and H. Taya (see [11] and the references there). We will apply our methods to this somewhat different case in a separate paper.

The results of the calculations are presented in Table 5.2. It turns out that the sequence of groups $A_0, A_1, A_2, \ldots$, stabilizes in all cases. As a consequence we can confirm Greenberg's conjecture in all cases:

**Theorem.** The Iwasawa $\lambda$-invariants associated to the $\mathbb{Z}_3$-extension of the real quadratic fields $\mathbb{Q}(\sqrt{f})$ of conductor $f < 10000$ with $f \equiv 1 \pmod{3}$ are all equal to zero.

In Section 2 we discuss some properties of cyclotomic units. In Sections 3 and 4 we present our algorithm and in Section 5 we give the results of our computations. For the cohomology and class field theory that we use, see [2].
2. Cyclotomic units

In this section we study the cyclotomic units in the $\mathbb{Z}_p$-extension of a real quadratic field in some detail. First we introduce some notation.

Let $F = \mathbb{Q}(\sqrt{f})$ be a real quadratic field of conductor $f$. Let $\sigma$ denote the non-trivial automorphism of $F$ and let $\chi(x) = \left( \frac{x}{\sigma} \right)$ be the Dirichlet character associated to $F$. Let $p$ be an odd prime and let

$$F = F_0 \subset F_1 \subset \cdots \subset F_n \subset \cdots$$

be the cyclotomic $\mathbb{Z}_p$ extension of $F$: every $F_n$ is of the form $FQ_n$ where $Q_n$ is the $n$th layer in the cyclotomic $\mathbb{Z}_p$-extension of $\mathbb{Q}$. The field $F_n$ is contained in $\mathbb{Q}(\zeta_{p^n+1}f)$ and is abelian over $\mathbb{Q}$. Let $G_n = \text{Gal}(F_n/F_0)$; it is a cyclic group of order $p^n$.

For any $n \geq 0$, let $\mathcal{O}_n^*$ denote the unit group of the ring of integers $\mathcal{O}_n$ of $F_n$, let $\text{Cyc}_n$ denote the subgroup of $\mathcal{O}_n^*$ of cyclotomic units and $\text{Cl}_n$ the ideal class group of $\mathcal{O}_n$. We use the definition of $\text{Cyc}_n$ as in Sinnott's paper [10, Sect. 4].

All these groups admit an action by the Galois group $\text{Gal}(F_n/Q_n) \cong \text{Gal}(F/Q) = \{\sigma, \text{id}\}$. We use this action to split the modules into an invariant and anti-invariant piece. The anti-invariant pieces are important for us. They are defined as follows: $\mathcal{O}_n^*(\sigma) = (\mathcal{O}_n^* \otimes \mathbb{Z}_p)^{\sigma-1}$ and similarly $\text{Cyc}_n(\sigma) = (\text{Cyc}_n \otimes \mathbb{Z}_p)^{\sigma-1}$ and $\text{Cl}_n(\sigma) = (\text{Cl}_n \otimes \mathbb{Z}_p)^{\sigma-1}$.

**DEFINITION.** The $n$th cyclotomic unit $\eta_n \in F_n$ is defined by

$$\eta_n = \text{Norm}_{Q(\zeta_{f'p^n+1})/F_n} \left( 1 - \zeta_{f'p^n+1} \right)^{1-\sigma};$$

here $f' = f/p$ when $p$ divides $f$ (or equivalently: when $\chi(p) = 0$) and $f' = f$ otherwise.

From now on we assume that

$$\chi(p) = \left( \frac{f}{p} \right) \neq 1.$$

It follows from [10, Thm. 4.1 and Thm. 5.3] that in this case the index $[\mathcal{O}_n^* : \text{Cyc}_n]$ is, up to a $p$-adic unit, equal to the class number $\#\text{Cl}_n$. It follows from the distribution relations for the cyclotomic units, that, up to exponents of the form $\chi(p) - 1$, the cyclotomic units $\eta_k$, for $k < n$ and the cyclotomic unit $\text{Norm}_{Q(\zeta_f)/F_0}(1 - \zeta_f)^{1-\sigma}$ are all norms of $\eta_n$. Therefore $\eta_n$ generates $\text{Cyc}_n(\chi)$ as a $\mathbb{Z}_p[G_n]$-module. In other words, the map

$$\mathbb{Z}_p[G_n] \to \text{Cyc}_n(\chi)$$

given by $x \mapsto \eta_n^x$ is surjective. Since both $\mathbb{Z}_p[G_n]$ and $\text{Cyc}_n(\chi)$ are free $\mathbb{Z}_p$-modules of rank $p^n$, the map is an isomorphism and we see that $\text{Cyc}_n(\chi)$ is free of rank 1 over $\mathbb{Z}_p[G_n]$ generated by $\eta_n$. 
For convenience sake we let

\[
A_n = Cl_n(\chi), \\
B_n = O_n^*(\chi)/Cyc_n(\chi), \\
C_n = \text{Hom}(B_n, \mathbb{Q}/\mathbb{Z}).
\]

The groups \(B_n\) and \(C_n\) have the same order as \(A_n\):

\[
h_n = \#A_n = \#B_n = \#C_n.
\]

This follows from the decomposition of the zeta-function of \(F_n\) into a product of \(L\)-series [12]. In general, the groups \(A_n\) and \(B_n\) are not isomorphic. Recall that the action of the Galois group \(G_n\) on \(C_n\) is given by

\[
\gamma(f)(u) = f(\gamma^{-1}(u)), \quad \gamma \in G_n, \ u \in B_n.
\]

In order to study the growth of the class groups \(A_n\) in the \(\mathbb{Z}_p\)-extension, we may as well study the groups \(B_n\), which are easier to compute. It turns out to be even more convenient to study the dual groups \(C_n\).

For any \(n \geq m \geq 0\) let \(G_{n,m}\) denote the group \(\text{Gal}(F_n/F_m)\). It is a cyclic group of order \(p^{n-m}\).

**Lemma 2.1.** Let \(n \geq m \geq 0\). Then the natural map

\[
B_m \longrightarrow B_n^{G_{n,m}}
\]

is an isomorphism.

**Proof.** Since \(\text{Cyc}_n(\chi)\) is a free \(\mathbb{Z}_p[G_n]\)-module, the cohomology group \(H^1(G_{n,m}, \text{Cyc}_n(\chi))\) is trivial. Now apply the snake lemma to the following diagram.

\[
\begin{array}{ccccccccc}
0 & \longrightarrow & \text{Cyc}_n(\chi) & \longrightarrow & O_n^*(\chi) & \longrightarrow & B_m & \longrightarrow & 0 \\
& \downarrow & \cong & \downarrow & \cong & \downarrow & & & \\
0 & \longrightarrow & \text{Cyc}_n(\chi)^{G_{n,m}} & \longrightarrow & O_n^*(\chi)^{G_{n,m}} & \longrightarrow & B_n^{G_{n,m}} & \longrightarrow & 0
\end{array}
\]

This proves the lemma. \(\square\)

The following proposition enables us to decide whether the sequence of groups

\[
B_0 \hookrightarrow B_1 \hookrightarrow B_2 \hookrightarrow \cdots
\]

stabilizes.

**Proposition 2.2.** (Stabilization.) If \(\#B_m = \#B_{m+1}\) for some \(m \geq 0\), then the natural map \(B_m \rightarrow B_n\) is an isomorphism for all \(n \geq m\).
Proof. Let \( n \geq m + 1 \) and let \( \gamma \) denote a generator of \( G_{n,m} \). The group ring \( \mathbb{Z}_p[G_{n,m}] \) is a local ring with maximal ideal \( m = (\gamma - 1, p) \). By Lemma 2.1 the groups \( B_m \) and \( B_{m+1} \) are precisely the invariants of \( G_{n,m} \) and its subgroup \( G_{n,m+1} \) respectively. In other words \( B_m = \ker(\gamma - 1) \) and \( B_{m+1} = \ker(\gamma^p - 1) \). Since these groups have the same cardinality, the same is true for \( (\gamma - 1)B_n \) and \( (\gamma^p - 1)B_n \). This implies that \[
(\gamma - 1)B_n = (\gamma^p - 1)B_n = (\gamma^{p-1} + \cdots + \gamma + 1)(\gamma - 1)B_n \subset m(\gamma - 1)B_n.
\]
By Nakayama's Lemma we therefore have that \( (\gamma - 1)B_n = 0 \). This implies that \( B_n \) is \( G_{n,m} \)-invariant and hence equal to \( B_m \) as required. \( \square \)

In the computations we will use the following, obviously equivalent, form of Proposition 2.2:

**Corollary 2.3.** If \( \#C_m = \#C_{m+1} \) for some \( m \geq 0 \), then the norm map \( A_n \to A_m \) is an isomorphism for all \( n \geq m \).

We now study the structure of the groups \( C_n \) in some more detail. It is convenient to introduce the projective limit

\[
C = \text{lim}^{-} C_n.
\]
Here the transition maps \( C_n \to C_m \) (for \( n \geq m \)) are the duals of the natural maps \( B_m \to B_n \). The group \( C \) is a module over the projective limit of the rings \( \mathbb{Z}_p[G_n] \), which is isomorphic to the Iwasawa algebra \( \Lambda = \mathbb{Z}_p[[T]] \). Here \( 1 + T \) corresponds to the topological generator \( 1 + p \) of the projective limit \( 1 + p\mathbb{Z}_p \) of the groups \( G_n \cong 1 + p\mathbb{Z}/p^{n+1}\mathbb{Z} \). One has that

\[
\mathbb{Z}_p[G_n] = \Lambda/(\omega_n) \quad \text{for each} \ n \geq 0,
\]
where \( \omega_n \) denotes \( (1 + T)^n - 1 \).

**Theorem 2.4.**

(i) There is an isomorphism of \( \Lambda \)-modules

\[
C \cong \Lambda / I \quad \text{for some} \ \Lambda \text{-ideal} \ I.
\]

Moreover, for each \( n \geq 0 \) we have

\[
C_n \cong \Lambda / (\omega_n, I).
\]

(ii) For every \( k, n \geq 0 \), there is a canonical \( G_n \)-isomorphism

\[
C_n/p^k C_n \cong \mathbb{Z}/p^k\mathbb{Z}[G_n]/\{f(\eta_n) : f \in \text{Hom}_{G_n}(O^*(\chi), \mathbb{Z}/p^k\mathbb{Z}[G_n])\}.
\]
Proof. (i) Since $C/TC$ is dual to the cyclic group $B_0$, it follows from Nakayama's Lemma that $C$ is a cyclic $\Lambda$-module. The fact that $C_n \cong \Lambda/(\omega_n, I)$ follows by dualizing from Lemma 2.1.

(ii) Let $n \geq 0$ and let $p^k$ be a power of $p$. Consider the diagram

$$
\begin{array}{cccccc}
0 & \longrightarrow & \text{Cyc}_n(\chi) & \longrightarrow & O_n^* (\chi) & \longrightarrow & B_n & \longrightarrow & 0 \\
\downarrow{p^k} & & \downarrow{p^k} & & \downarrow{p^k} & & \\
0 & \longrightarrow & \text{Cyc}_n(\chi) & \longrightarrow & O_n^* (\chi) & \longrightarrow & B_n & \longrightarrow & 0
\end{array}
$$

By the snake lemma this gives an exact sequence

$$0 \to B_n[p^k] \to \text{Cyc}_n(\chi)/\{p^k\text{th powers}\} \to O_n^* (\chi)/\{p^k\text{th powers}\}.$$ 

All Galois modules in this sequence are killed by $p^k$. Therefore they are $\mathbb{Z}/p^k\mathbb{Z}[G_n]$-modules. The finite ring $R_n = \mathbb{Z}/p^k\mathbb{Z}[G_n]$ is a Gorenstein ring (see appendix of [7] for definition and basic properties). This means that $\text{Hom}_\mathbb{Z}(R_n, \mathbb{Q}/\mathbb{Z})$ is a free $R_n$-module of rank 1. Therefore the canonical isomorphism $\text{Hom}_{G_n}(M, \text{Hom}_\mathbb{Z}(R_n, \mathbb{Q}/\mathbb{Z})) \cong \text{Hom}_\mathbb{Z}(M, \mathbb{Q}/\mathbb{Z})$ gives rise to an isomorphism

$$\text{Hom}_{G_n}(M, R_n) \cong \text{Hom}_\mathbb{Z}(M, \mathbb{Q}/\mathbb{Z}),$$

for every finite $R_n$-module $M$. The isomorphism is given by $f \mapsto \psi \circ f$ for some chosen $R_n$-generator $\psi : R_n \to \mathbb{Q}/\mathbb{Z}$. This shows that the contravariant functor $\text{Hom}_{G_n}(\cdot, R_n)$ is exact. Applying it to the exact sequence above gives us the exact sequence

$$\text{Hom}_{G_n}(O_n^* (\chi), R_n) \to \text{Hom}_{G_n}(\text{Cyc}_n(\chi), R_n) \to C_n/p^kC_n \to 0.$$ 

Since $\text{Cyc}_n(\chi)$ is free with generator $\eta_n$, we can identify $\text{Hom}_{G_n}(\text{Cyc}_n(\chi), R_n)$ with the ring $R_n$ itself via $f \mapsto f(\eta_n)$. We obtain

$$C_n/p^kC_n \cong R_n/\{f(\eta_n) : f \in \text{Hom}_{G_n}(O_n^* (\chi), R_n)\}$$

as required. $\square$

For computational purposes, it is convenient to make part (ii) of this theorem more explicit. We can exhibit many $G_n$-homomorphisms $f : O_n^* (\chi) \to \mathbb{Z}/p^k\mathbb{Z}[G_n]$ as follows: let $r$ be a prime number which is split in $F_n$ and which is 1 (mod $p^k$). We have the reduction modulo $r$ map

$$f_r : O_n^* \to (O_n/rO_n)^* \cong \bigoplus_{p|r}(O_n/p)^*.$$

For every $p$, raising to the power $(r-1)/p^k$ gives a surjective homomorphism $(O/p)^* \to \mathbb{Z}/p^k\mathbb{Z}$. Since all primes $p$ over $r$ are permuted by the Galois group $G_n$, we obtain, by taking $\chi$-parts, a $G_n$-homomorphism

$$f_r : O_n^* (\chi) \to \mathbb{Z}/p^k\mathbb{Z}[G_n]$$
which we also denote by $f_r$.

**PROPOSITION 2.5.** Let $k \geq 1$ and $n \geq 0$. Every $G_n$-homomorphism $f: O^*_n(\chi) \to \mathbb{Z}/p^k\mathbb{Z}[G_n]$ is of the form $f_r$ for some prime $r$ which is split in $F_n(\zeta_{p^k})$.

**Proof.** Let $\kappa = \max(k-1, n)$. Then both $O^*_n$ and $\zeta_{p^k}$ are contained in $F_\kappa(\zeta_p)$. By Kummer theory we have the following diagram:

\[
\varphi_r \in \text{Gal}(F^*_{\kappa}(\zeta_p), F^*_{\kappa}(\zeta_p)) \quad \longrightarrow \quad \varphi_r \\
\text{Hom}(O^*_{n}(\chi)/O^*_{n}(\chi) \cap (O^*_{F_\kappa(\zeta_p)})^p, \mu_{p^k}) \quad \downarrow \quad \varphi_r \\
\text{Hom}(O^*_n(\chi)/O^*_n(\chi)^{p^k}, \mu_{p^k}) \quad \downarrow \quad \varphi_r \\
\text{Hom}(O^*_n(\chi)/O^*_n(\chi)^{p^k}, \mathbb{Q}/\mathbb{Z}) \quad \downarrow \quad \varphi_r \\
f_r \in \text{Hom}_{G_n}(O^*_n(\chi), \mathbb{Z}/p^k\mathbb{Z}[G_n])
\]

Here the Frobenius element $\varphi_r$ of $r$ is mapped to the homomorphism $f_r$. The second isomorphism follows from the fact that the map $F^*_n/(F^*_n)^{p^k} \to F^*_\kappa(\zeta_p)^*/(F^*_\kappa(\zeta_p)^*)^{p^k}$ is injective, because its kernel, which is isomorphic to $H^1(\text{Gal}(F^*_\kappa(\zeta_p), F_n), \mu_{p^k})$ is trivial. This follows from the exact restriction-inflation sequence

\[0 \to H^1(G_{\kappa,n}, \mu_{p^k}) \to H^1(\text{Gal}(F^*_\kappa(\zeta_p), F_n), \mu_{p^k}) \to H^1(\Delta, \mu_{p^k})\]

and the fact that $\Delta = \text{Gal}(F^*_\kappa(\zeta_p), F_\kappa)$ has order prime to $p$ and that $\mu_{p^k}^{\Delta} = \{1\}$.

By the Cebotarev density theorem, every element in $\text{Hom}(O^*_n(\chi), \mathbb{Z}/p^k\mathbb{Z}[G_n])$ is of the form $f_r$. This proves the proposition. $\Box$

This gives us an explicit description of the modules $C_n/p^kC_n$:

\[C_n/p^kC_n \cong \mathbb{Z}/p^k\mathbb{Z}[G_n]/\{f_r(\eta_n) : r \text{ is split in } F_n(\zeta_{p^k})\}.
\]
Next we explain how to recover the structure of the class groups $A_n$ and the maps $A_m \to A_n$ from the structure of the $\Lambda$-module $C$. First we establish the following remarkable relation between the class groups $A_n$ and the groups of units modulo cyclotomic units $B_n$:

**PROPOSITION 2.6.** Suppose that the sequence of modules $C_n$ stabilizes: $C = C_n$ if for $n \geq n_0$ (i.e. "$\lambda = 0$"). Then there is an isomorphism of $G_n$-modules

$$A_n \cong B_n \quad \text{for } n \geq n_0.$$

*Proof.* Let $n \geq m \geq 0$. Let $G_{n,m} = \text{Gal}(F_n/F_m)$. Since $\chi \neq 1$, the $\chi$-part of the $G_{n,m}$-cohomology groups of the idèle class group of $F_n$ is trivial. Since $\chi(p) \neq 1$, the $\chi$-part of the $G_{n,m}$-cohomology groups of the group of unit idèles of $F_n$ is also trivial [9, Sect. 4]. This implies that there is a canonical isomorphism

$$\hat{H}^q(G_{n,m}, O_n^*(\chi)) \cong \hat{H}^{q-2}(G_{n,m}, A_n), \quad \text{for all } q \in \mathbb{Z}.$$

Since the group $\text{Cyc}_n(\chi)$ is cohomologically trivial and since $G_n$ is cyclic this implies that there is a $G_m$-isomorphism

$$\hat{H}^q(G_{n,m}, B_n) \cong \hat{H}^q(G_{n,m}, A_n), \quad \text{for all } q \in \mathbb{Z}.$$

Since $\lambda = 0$, the groups $A_n$ and $B_n$ stabilize. Therefore there is an integer $N$ such that $N$th power of the maximal ideal $m = (p, T)$ of $\Lambda$ kills both $A_n$ and $B_n$ for all $n$. Take $m \geq N$ and $n = 2m$. Then both $\omega_m$ and the $G_{n,m}$-norm are contained in $m^N$. Therefore $\hat{H}^0(G_{n,m}, B_n) = B_n$ and $\hat{H}^0(G_{n,m}, A_n) = A_n$.

This implies that $A_n \cong B_n$ as $G_n$-modules for large $n$ and therefore for each $n \geq n_0$. This proves the proposition. \qed

**PROPOSITION 2.7.** Suppose that the sequence of modules $C_n$ stabilizes: $C = C_n$ if for $n \geq n_0$. Then

(i) there is for each $m \geq 0$ an exact sequence

$$0 \to A_{m}^{\text{dual}} \to C \xrightarrow{\omega_m} C \to B_{m}^{\text{dual}} \to 0.$$

(ii) For every $0 \leq m \leq m'$ there is a commutative diagram:

$$\begin{array}{ccc}
A_{m}^{\text{dual}} & \xrightarrow{\cong} & C[\omega_{m'}] \\
| & & | \\
| & j_{m,m'}^{\text{dual}} & \downarrow N_{m',m} \\
A_{m}^{\text{dual}} & \xrightarrow{\cong} & C[\omega_{m}] \\
\end{array}$$

Here $j_{m,m'}$ denotes the natural map $A_m \to A_{m'}$. 
Proof. Suppose that \( N \geq n_0 \) is so large that \( m^N \) kills \( C \). Let \( n \geq m + N \). Then the norm map \( \text{norm} : \mathbb{N} \to \mathbb{N} \) is contained in \( m^N \) and the kernel of the map \( \omega_m : C \to C \) is the zeroth \( \mathbb{G}_{n,m} \)-Tate cohomology group of \( C_n \). By cohomological duality, this group is dual to \( \tilde{H}^1(G_{n,m}, B_n) \cong \tilde{H}^1(G_{n,m}, O_n^*(\chi)) \). Since \( \chi(p) \neq 1 \) the \( \chi \)-part of the cohomology groups of the idèle units of \( F_n \) is trivial. This implies that

\[
\ker(A_m \to A_n) \cong H^1(G_{n,m}, O_n^*(\chi)).
\]

Therefore \( C[\omega_m] \) is dual to \( \ker(A_m \to A_n) \), which is just \( A_m \) if \( n \) is sufficiently large. This proves part (i).

To prove (ii) it suffices to observe that the following diagram is commutative

\[
\begin{array}{ccccccc}
0 & \longrightarrow & A_m & \longrightarrow & C & \longrightarrow & B_m & \longrightarrow & 0 \\
& & \downarrow{\text{dual}} & & \downarrow{\omega_m} & & \downarrow{\text{dual}} & & \\
0 & \longrightarrow & A_m & \longrightarrow & C & \longrightarrow & B_m & \longrightarrow & 0 \\
\end{array}
\]

We leave this straightforward verification to the reader. \( \square \)

It is well known that \( A_m \) is in general not isomorphic to \( B_m \). Therefore Proposition 2.6 does not hold for every \( n \geq 0 \). By Proposition 2.7 the group \( A_0 \) is dual to the kernel of \( T : C \to C \) while \( B_0 \) is dual to the cokernel \( C/TC \). Note that \( \ker(T) \) can be non-cyclic even though \( \text{cok}(T) \) is always cyclic. For instance, if \( I = m^j \), then

\[
\text{cok}(T) \cong \mathbb{Z}/p^j\mathbb{Z},
\]

\[
\ker(T) \cong \mathbb{Z}/p\mathbb{Z} \times \cdots \times \mathbb{Z}/p\mathbb{Z}.
\]

Two explicit examples of such ideals \( I \) are provided by \( f = 32009 \) and \( f = 62501 \). In both cases \( I = m^2 \) and the sequence of class groups stabilizes at level 1.

3. Upper bounds

In this section and the next we explain how we compute the groups \( C_n \). In this section we discuss our method to obtain upper bounds for the modules \( C_n \). In practice these upper bounds are actually sharp, but this is only verified by means of the calculations explained in Section 4 where we discuss our method to obtain rigorous lower bounds for the \( C_n \).
By Proposition 2.5 we have the following explicit expression:

$$C_n/p^kC_n = \mathbb{Z}/p^k\mathbb{Z}[G_n]/\{f_r : r \text{ is split in } F_n(\zeta_{p^k})\},$$

where we have written $f_r$ for $f_r(\eta_n)$. This result enables us to compute the modules $C_n$ at every level $n$: to calculate $C_n/p^kC_n$ for a given prime power $p^k$, we compute many elements $f_{r_1}, f_{r_2}, \ldots$. If we have computed "enough" of them, we have found the full ideal $\{f_r : r \text{ is split in } F_n(\zeta_{p^k})\}$ and hence, by Proposition 2.5, we know $C_n/p^kC_n$. If $C_n/p^kC_n$ is already killed by $p^{k-1}$, then apparently $C_n = C_n/p^kC_n$ and we have found $C_n$ itself. In practice we can rarely be sure to have computed sufficiently many elements $f_r$, but, in any case, $C_n/p^kC_n$ is a quotient of $\mathbb{Z}/p^k\mathbb{Z}[G_n]/\langle f_{r_1}, f_{r_2}, \ldots \rangle$. If in addition $p^{k-1}$ annihilates $C_n/p^kC_n$, we have therefore rigorously computed an "upper bound" for $C_n = C_n/p^kC_n$.

To investigate the behaviour in the $\mathbb{Z}_p$-extension, we compute the modules $C_0, C_1, C_2, \ldots$, as explained above. If one finds that $C_n = C_{n+1}$ for a certain $n$, then by Corollary 2.3 the modules $C_n$ stabilize at this point: $C_m = C_n$ for each $m \geq n$ and $C = C_n$.

In practice, one simply computes the groups $C_m/p^kC_m$ for some reasonably large $k$ at some moderately high levels $m = n$ and $m = n + 1$. When $C_{n+1}/p^kC_{n+1} = C_n/p^kC_n$ and this group is killed by $p^{k-1}$ one knows that $C_n = C_n/p^kC_n$ and that, most likely, $C = C_n$. One can recover the structure of the groups $A_n$ and $B_n$ at every level, by applying Proposition 2.7.

What do the $f_r$ look like on a computer? Identifying the generator $p+1$ of $G_n$ with $X$, we write

$$\mathbb{Z}/p^k\mathbb{Z}[G_n] \cong \mathbb{Z}/p^k\mathbb{Z}[X]/(X^{p^n} - 1).$$

In this way the elements $f_r$ become polynomials in $X$. The "logarithmic map" \( \log_p : (\mathbb{Z}_n/p)^* \to \mathbb{Z}/p^k\mathbb{Z} \) can be computed as follows: we choose (once and for all) a generator $\zeta$ for the subgroup of $p^k$th roots of unity in $\mathbb{Z}/p\mathbb{Z}$. Then $\log_p(x)$ is the discrete logarithm with respect to $\zeta$ of $x^{(r-1)/pk}$. Finally, rather than fixing a cyclotomic unit $1 - \zeta^{p^{n+1}}$ and permuting the prime ideals $\mathfrak{p}$ with the Galois group, we fix one prime ideal $\mathfrak{p}$ over $r$ and permute the cyclotomic units with the Galois group. The choices of $\zeta$ and $\mathfrak{p}$ are not important; they only change $f_r$ by a unit.

We only give the formula for $p = 3$. The condition $\chi(p) \neq 1$ means that $f \not\equiv 1$ (mod 3). When $f \equiv 2$ (mod 3) we get

$$f_r(\eta_n) = \sum_{y \in \mathbb{Z}/3^n\mathbb{Z}} \sum_{x \in (\mathbb{Z}/f\mathbb{Z})^*} \log_r \left( \frac{(1 - \zeta^{4y} \zeta_f^y)(1 - \zeta^{-4y} \zeta_f^y)}{(1 - \zeta^{4y} \zeta_f^{2y})(1 - \zeta^{-4y} \zeta_f^{2y})} \right) \cdot X^y. \quad (1)$$

Here $g \in (\mathbb{Z}/f\mathbb{Z})^*$ satisfies $(\frac{g}{3}) = -1$ and $\zeta$ is a primitive $3^{n+1}$th root of 1 modulo $r$. We have written $\log_r$ for $\log_p$; the summation over $x$ corresponds to the norm to $F_n(\zeta_3) = \mathbb{Q}(\zeta, \sqrt{f})$. 

The four factors inside the logarithm are projections into the correct \( \chi \)-eigenspace: the factors in the numerator correspond to the norm to \( F_n = Q_n(\sqrt{f}) \). The denominator is just \( \sigma \) applied to the numerator, where \( \sigma \) generates \( \text{Gal}(Q(\sqrt{f})/Q) \). In other words, the quantity in the log is just \((1 + \tau)(1 - \sigma)\) applied to \((1 - \zeta^{4^v} \zeta_f^x)\). Here \( \tau \) is the non-trivial automorphism of \( Q(\zeta_3) \). For computational purposes, the formulas should be modified a little. It is not difficult to see that, up to a 3-adic unit, we have

\[
f_r(\eta_n) = \sum_{y \in \mathbb{Z}/3^n\mathbb{Z}} \log_r \left( \prod_{x \in (\mathbb{Z}/f\mathbb{Z})^*} \left( \zeta^{4^v} - \zeta_f^x \right) \left( \frac{x}{\zeta_f^x} \right) \right) \cdot X^y \in \mathbb{Z}/3^k\mathbb{Z}[X]/(X^{3^n} - 1). \tag{2}
\]

When \( f \equiv 0 \pmod{3} \), the resulting formulas are practically the same as the ones for the case \( f \equiv 2 \pmod{3} \). There are slight differences because of the definition of the cyclotomic units. The analogue of formula (1) of the previous section is:

\[
f_r(\eta_n) = \sum_{y \in \mathbb{Z}/3^n\mathbb{Z}} \sum_{x \in (\mathbb{Z}/f\mathbb{Z})^*} \log_r \left( \frac{(1 - \zeta^{4^v} \zeta_f^x)}{(1 - \zeta^{4^v} \zeta_f^{4^v} \zeta_f^x)} \right) \cdot X^y. \tag{1'}
\]

Here \( f' \) denotes \( f/3 \). Since \( Q(\sqrt{f}) \) is a real quadratic field, \( Q(\sqrt{-f'}) \) is complex and \( (\frac{-1}{f'}) = -1 \). So, in terms of the formula in the case \( f \equiv 2 \pmod{3} \), we have taken \( g = -1 \) in this case. The sum over \( x \) corresponds to the norm to \( Q(\zeta, \sqrt{f'}) = F_n(\zeta_3, \sqrt{f'}) \). The products within the numerator and denominator correspond to the norm from \( F_n(\zeta_3, \sqrt{f'}) \) to \( Q_n(\sqrt{3f'}) = F_n \). Finally we project the unit into the \( \chi \)-eigenspace by applying \( 1 - \sigma \).

As in the case \( f \equiv 2 \pmod{3} \), we modify the formula a little bit. Proceeding as before, we find the following expression:

\[
f_r(\eta_n) = \sum_{y \in \mathbb{Z}/3^n\mathbb{Z}} \log_r \left( \prod_{x \in (\mathbb{Z}/f'\mathbb{Z})^*} \left( \zeta^{4^v} - \zeta_f^x \right) \left( \frac{x'}{\zeta_f^x} \right) \right) X^y \\
\in \mathbb{Z}/3^k\mathbb{Z}[X]/(X^{3^n} - 1). \tag{2'}
\]

Notice that this time \( \left( \frac{x'}{\zeta_f^x} \right) \) is an odd character.

When \( f \) is large, computing the product in (2) and (2') is a lot of work. It is important to first compute the products and then take their logarithms (only \( 3^n \) of them). Usually, it is not necessary to take \( n \) large than 0 or 1, because the class groups are all trivial or stabilize immediately. Occasionally, however, one may wish to consider \( n = 2, 3, 4, \ldots \). In these cases it might be useful to have a table of the quadratic residue symbols modulo \( f \). So far, we have always recomputed
all of them for each new auxiliary prime \( r \). The choice of \( k \) hardly effects the running times when \( n \) is small: computing modulo \( 3^{10} \) is as efficient as computing modulo 3; only computing the few discrete logarithms is a lot slower when \( k \) is large.

In order to compute the ideal generated by the \( f_r \) in the ring \( \mathbb{Z}/p^k \mathbb{Z}[X]/(X^{p^n} - 1) \) it is convenient to convert everything to the parameter \( T = X - 1 \). Then the ring becomes isomorphic to \( \mathbb{Z}/p^k \mathbb{Z}[T]/(\omega_n) \) where \( \omega_n = (1 + T)^{p^n} - 1 \). This is a finite local ring with maximal ideal \((p, T)\). It is a Gorenstein ring and its unique minimal ideal is generated by \( p^{k-1}T^{p^n-1} \).

In our case

\[
f_r \in \mathbb{Z}/3^{k+1} \mathbb{Z}[T]/((1 + T)^{3^n} - 1).
\]

In practice, we apply the Weierstraß-Preparation Theorem and compute the “distinguished parts” of \( f_r \), i.e. we compute a Weierstraß polynomial \( \tilde{f}_r \) such that \( f_r = \tilde{f}_r \) up to a unit.

**EXAMPLE 3.1.** This is an example of what usually happens: let \( f = 761 \). In this case \( h_0 = 3 \). We take, somewhat arbitrarily, \( p^k = 27 \) and \( n = 1 \). So, the coefficients of the \( f_r \) are computed modulo 27 and the \( f_r \) are elements of the ring \( \mathbb{Z}/27 \mathbb{Z}[T]/(T^3 + 3T^2 + 3T) \).

It is easily seen that the \( f_r \) generate the maximal ideal \( m \) of \( \Lambda/(\omega_1) \) in this case. Therefore

\[
C_1 \cong \Lambda/m \cong \mathbb{Z}/3\mathbb{Z} \cong C_0.
\]

By Proposition 2.2, this implies that \( C = C_1 = C_0 \). Note that, since \( \Lambda/(\tilde{f}_{r_1}, \ldots, \tilde{f}_{r_t}) \) is certainly an upper bound for \( C \), we have a complete proof in this case: the tower of class groups stabilizes immediately at level 0. All the norm maps in the towers are isomorphisms and all the maps \( j_{m,m'}: A_m \to A_{m'} \) are zero \( (m < m') \).

**EXAMPLE 3.2.** \( f = 4749 \). Here’s an example where the class groups grow a little bit in the \( \mathbb{Z}_3 \)-extension. The class group of \( \mathbb{Q}(\sqrt{f}) \) is cyclic of order 3. We compute the following elements at level 1 modulo 27:
All polynomials have 3 as a zero modulo 9. We move to level 2 and compute the following elements modulo the ideal \((03C92, 81)\):

<table>
<thead>
<tr>
<th>(r)</th>
<th>(\hat{f}_r)</th>
</tr>
</thead>
<tbody>
<tr>
<td>683857</td>
<td>(T + 6)</td>

<td>1624159</td>
<td>(T + 24)</td>
</tr>
<tr>
<td>2222533</td>
<td>(T + 6)</td>
</tr>
<tr>
<td>2393497</td>
<td>(T + 15)</td>
</tr>
</tbody>
</table>

Once more, all polynomials \(\hat{f}_r\) have 3 as a zero; this time modulo 27. Once more, we move up one level in the \(\mathbb{Z}_3\)-extension. At level 3, modulo the ideal \((\omega_3, 243)\) we find

<table>
<thead>
<tr>
<th>(r)</th>
<th>(\hat{f}_r)</th>
</tr>
</thead>
<tbody>
<tr>
<td>769339</td>
<td>(T + 24)</td>
</tr>
<tr>
<td>1282231</td>
<td>(T^5 + 60T^4 + 63T^3 + 3T^2 + 39T + 45)</td>
</tr>
<tr>
<td>3846691</td>
<td>(T + 51)</td>
</tr>
<tr>
<td>4359583</td>
<td>(T + 24)</td>
</tr>
<tr>
<td>5898259</td>
<td>(T + 24)</td>
</tr>
<tr>
<td>6667597</td>
<td>(T + 51)</td>
</tr>
<tr>
<td>7180489</td>
<td>(T + 51)</td>
</tr>
</tbody>
</table>

This time the polynomials again generate the ideal \((T - 3, 27)\). Since the computations were done modulo \(3^5\), we conclude that the module \(C_3/3^5C_3\) is equal to \(C_3\). Since we tried so many primes \(r\) we are actually led to believe that the class groups stabilize at this point and that

\[
C \cong C_3 \cong \Lambda/(T - 3, 27) \cong \mathbb{Z}/27\mathbb{Z}.
\]
Taking covariants we see that $C_0 \cong \mathbb{C}/\mathbb{C} \cong \mathbb{Z}/3\mathbb{Z}$. Similarly $C_1 \cong \mathbb{C}/\mathbb{C} \cong \mathbb{Z}/9\mathbb{Z}$ and $C_2 = C \cong \mathbb{Z}/27\mathbb{Z}$. Using Proposition 2.7 one easily sees that $A_0, A_1, A_2$ are cyclic of order 3, 9 and 27 respectively. The maps $A_0 \hookrightarrow A_1 \hookrightarrow A_2$ are injective. It is not difficult to see that, in general, all ideal classes in $A_k$ become only trivial in $A_{k+3}$.

EXAMPLE 3.3. $f = 6396$. This is a somewhat "exotic" example. We computed the following polynomials modulo 27 at level 1.

<table>
<thead>
<tr>
<th>$r$</th>
<th>$\tilde{f}_r$</th>
</tr>
</thead>
<tbody>
<tr>
<td>230257</td>
<td>$T^2 + 21T + 3$</td>
</tr>
<tr>
<td>287821</td>
<td>$T^2 + 24T + 21$</td>
</tr>
<tr>
<td>462949</td>
<td>$T^2 + 24T + 21$</td>
</tr>
<tr>
<td>1036153</td>
<td>$T^2 + 21T + 12$</td>
</tr>
<tr>
<td>1093717</td>
<td>$T^2 + 6T + 21$</td>
</tr>
<tr>
<td>1266409</td>
<td>$9T$</td>
</tr>
<tr>
<td>1381537</td>
<td>$T^2 + 3T + 21$</td>
</tr>
</tbody>
</table>

The polynomials $\tilde{f}_r$ generate the $\Lambda$-ideal $(T^2 + 3, 3T, 9)$. At level 2 we find, computing modulo 27,

<table>
<thead>
<tr>
<th>$r$</th>
<th>$\tilde{f}_r$</th>
</tr>
</thead>
<tbody>
<tr>
<td>230257</td>
<td>$T^2 + 12T + 12$</td>
</tr>
<tr>
<td>287821</td>
<td>$T^2 + 15T + 21$</td>
</tr>
<tr>
<td>462949</td>
<td>$T^2 + 24T + 21$</td>
</tr>
<tr>
<td>1036153</td>
<td>$T^2 + 21T + 12$</td>
</tr>
<tr>
<td>1093717</td>
<td>$T^2 + 6T + 12$</td>
</tr>
<tr>
<td>1266409</td>
<td>$T^3 + 3T^2 + 21T$</td>
</tr>
<tr>
<td>1381537</td>
<td>$T^2 + 12T + 3$</td>
</tr>
</tbody>
</table>

The $\tilde{f}_r$ generate the same ideal as before. This proves that $C$ is isomorphic to a quotient of $\Lambda/(T^2 + 3, 3T, 9)$. In the next section we describe the computations that prove that actually $C \cong \Lambda/(T^2 + 3, 3T, 9)$.

4. Lower bounds

Our method to prove that the $\Lambda$-modules $\Lambda/(f_r_1, \ldots, f_r_t)$ that we have computed using the method of Section 3 are actually equal to the module $C$, is similar to the one employed by G. Gras and M.-N. Gras in [3]. It is based on very accurate approximations of the cyclotomic units in $R$. If one only wants to show that $\lambda = 0$, one can avoid the computations of this section as follows. If $\lambda > 0$, then by
Proposition 2.2 we have that \#C_n \geq p^{n+1} for every n \geq 0. Therefore it suffices to show that \#C_n \leq p^n for some n and this can be done using the method of the previous section.

Let \( p^k \) be a power of \( p \) and let \( n \geq 0 \). We let

\[ R_n = \mathbb{Z}/p^k\mathbb{Z}[G_n]. \]

We saw in the proof of Theorem 2.4 that this ring is a Gorenstein ring and that the \( R_n \)-module \( \text{Hom}_{\mathbb{Z}}(R_n, \mathbb{Q}/\mathbb{Z}) \) is free over \( R_n \) of rank 1. For every finite \( R_n \)-module \( M \) there is an isomorphism \( \text{Hom}_{\mathbb{Z}}(M, \mathbb{Q}/\mathbb{Z}) \cong \text{Hom}_{R_n}(M, \text{Hom}_{\mathbb{Z}}(R_n, \mathbb{Q}/\mathbb{Z})) \cong \text{Hom}_{R_n}(M, R_n) \). Because of our identification of \( \text{Hom}_{\mathbb{Z}}(R_n, \mathbb{Q}/\mathbb{Z}) \) with \( R_n \), this is, in general, not an isomorphism of \( R_n \)-modules. For instance, when \( M \) is an \( R_n \)-ideal \( I \), we have that \( \text{Hom}(I, \mathbb{Q}/\mathbb{Z}) \cong \text{Hom}_{R_n}(I, R_n) \cong \text{Ann}(I) \), but the natural actions of \( G_n \) on \( \text{Hom}(I, \mathbb{Q}/\mathbb{Z}) \) and \( \text{Ann}(I) \) do not agree. One is the inverse of the other.

Let \( \sigma : R_n \to R_n \) denote the involution of \( R_n \) induced by \( \sigma \mapsto \sigma^{-1} \) for \( \sigma \in G_n \). If \( A \subset R_n \) is any subset, then \( \hat{A} \) denotes the subset \( \{ \hat{x} : x \in A \} \).

Our method is based on the following proposition.

**Proposition 4.1.** Let \( n \geq 0 \) and let \( p^k \) be a power of \( p \) that annihilates \( C_n \) (and hence \( B_n \)). Let \( R_n \) denote the group ring \( \mathbb{Z}/p^k\mathbb{Z}[G_n] \) and let \( I_n \) be an \( R_n \)-ideal that annihilates \( C_n \). Then \( C_n \cong R_n/I_n \) if and only if \( \text{Ann}(\hat{I}_n) \) annihilates the module \( \text{Cyc}_n(\chi)/O^*_n(\chi)p^k \).

**Proof.** From the diagram of the proof of Theorem 2.4 we obtain the exact sequence

\[ 0 \to B_n \to \text{Cyc}_n(\chi)/\text{Cyc}_n(\chi)p^k \to \text{Cyc}_n(\chi)/O^*_n(\chi)p^k \to 0, \]

where the first arrow is given by \( \varepsilon \mapsto \varepsilon p^k \).

Since \( \text{Cyc}_n(\chi)/\text{Cyc}_n(\chi)p^k \) is free of rank 1 over \( R_n \), we see that \( \text{Ann}(\hat{I}_n) \) annihilates the module \( \text{Cyc}_n(\chi)/O^*_n(\chi)p^k \) if and only if \( B_n \cong J \) for some \( R_n \)-ideal \( J \) containing \( \text{Ann}(\hat{I}_n) \). Since \( R_n \) is a Gorenstein ring, this means that \( C_n \cong \text{Hom}_{R_n}(J, R_n) \cong R_n/\text{Ann}(J) \) and that \( C_n \) admits a surjective \( R_n \)-morphism \( C_n \to R_n/\text{Ann}(\text{Ann}(I_n)) \). Since \( I_n = \text{Ann}(\text{Ann}(I_n)) \), we see that \( \text{Ann}(\hat{I}_n) \) annihilates \( \text{Cyc}_n(\chi)/O^*_n(\chi)p^k \) if and only if there is a surjective \( R_n \)-morphism \( C_n \to R_n/I_n \). The proposition now follows from the fact that \( I_n \) kills \( C_n \).

We use this proposition as follows: suppose we know that \( C_n \) is annihilated by \( p^k \) and that it is a quotient of \( R_n/I_n \) for some ideal \( I_n \). To prove that \( C_n \cong R_n/I_n \) we compute a finite set \( \Sigma \) of generators of the ideal \( \text{Ann}(\hat{I}_n) \subset R_n \) and we attempt to show that each \( x \in \Sigma \) annihilates \( \text{Cyc}_n(\chi)/O^*_n(\chi)p^k \), i.e.,

\[ \eta_n^x \in O^*_n p^k \quad \text{for} \quad x \in \Sigma. \]
To show this, we compute very accurate approximations \( \eta^{(i)} \in \mathbb{R} \) to \( \eta_n \) and its conjugates. From these approximations we compute the minimal polynomial \( F(Y) \in \mathbb{Z}[Y] \) of \( \eta_n \). This polynomial has degree \( 2p^n \). For each \( x \in \Sigma \) we pick a representative \( x \in \mathbb{Z}[G_n] \) with small coefficients

\[
x = \sum_{k=1}^{p^n} a_k \gamma^k, \quad a_k \in \mathbb{Z}, |a_k| < p^k/2...
\]

Here \( \gamma \in G_n \) is the generator corresponding to \( p + 1 \) and \( T + 1 \). Next we compute very accurate approximations \( \varepsilon^{(i)} \in \mathbb{R} \) of \( \eta^{(i)} \) and use these to compute the minimum polynomial \( G(Y) \in \mathbb{Z}[Y] \) of \( \varepsilon \). Finally we compute the \( p^k \)th roots of the \( \varepsilon^{(i)} \) and the polynomial

\[
H(Y) = \prod_{i=1}^{2p^n} \left( Y - p^k \sqrt[2p^n]{\varepsilon^{(i)}} \right) \in \mathbb{R}[Y].
\]

If indeed \( \eta^x \in \mathbb{O}_n^{p^k} \), then the polynomial \( H(Y) \) has integral coefficients. In practice one is quickly convinced when one finds that the coefficients of \( H \) are very close to integers. However, this time one does not yet know that the zeroes are contained in a field of degree \( 2p^n \). One can prove this by checking that the integral polynomial close to \( H(Y) \) divides the polynomial \( G(Y^{p^k}) \). This completes the description of the method.

In practice the polynomials \( F, G \) and \( H \) have gigantic coefficients. Therefore it is necessary to use extremely accurate approximations of the cyclotomic units. For the sake of efficiency we begin our computation of the \( \eta^{(i)} \) using only a moderate accuracy of 100 or so decimal digits, just enough to "recognize" the integral coefficients of the polynomial \( F(Y) \in \mathbb{Z}[Y] \). Then we recompute the \( \eta^{(i)} \) using Newton's method. This is very efficient and provides us without excessive effort with an accuracy of 500–5000 decimal digits. The computation of the polynomials \( G(Y) \) and \( H(Y) \) is then completed using these high accuracy approximations.

We discuss only one fairly small example. See Example 3.3 for the upper bounds in this case. We used UBASIC and PARI to do the calculations. In the cases where the class groups seemed to stabilize at level 2 in the tower, it was necessary to do the computations with an accuracy of several thousands of decimal digits.

**EXAMPLE 4.2.** \( f = 6396 \). In this case the \( \Lambda \)-ideal that we have found with the method of Section 3 is \( (T^2 + 3, 3T, 9) \). Therefore \( C \) is a quotient of the module \( \Lambda/(T^2 + 3, 3T, 9) \). Since \( \omega_1 = T^3 + 3T^2 + 3T \in I \), we have \( C = C_1 \). We take \( p^k = 9 \).
We must show that $C_1 \cong R_1/I_1$. Here $R_1 = \mathbb{Z}/9\mathbb{Z}[T]/(T^3 + 3T^2 + 3T)$ and $I_1 = (T^2 + 3, 3T)$. The annihilator $\text{Ann}(\hat{I}_1)$ is $(T^2, 3T)$. Let $\gamma$ denote the generator of $G_1$ corresponding to $T + 1$. We have to show that

$$\eta_1^{3(\gamma-1)} \quad \text{and} \quad \eta_1^{(\gamma-1)^2}$$

are ninth powers in $O_1^*$. Equivalently, we must check the following:

$$\varepsilon = \gamma(\eta_1)\eta_1^{-1} \quad \text{is a cube in } O_1^*?$$
$$\varepsilon' = \gamma^2(\eta_1)\gamma(\eta_1)^{-2}\eta_1 \quad \text{is a ninth power in } O_1^*?$$

To do this we first compute, for $i = 1, 2, \ldots, 6$, the approximations $\eta^{(i)} \in \mathbb{R}$ to $\eta_1$:

$$\eta^{(1)} = 10675494700636200658242.740540292555723835910871383683 \quad 866586357611513327567014852500109494561638321936678 \quad 5534783752726237577990729350374469425598374086458010 \quad 5998766704\ldots$$

$$\eta^{(2)} = 0.00000000000000000936724740203754220747270048 \quad 39536557434046098945063531230922449635694024565429 \quad 544350150600582766365281775623597235308105397\ldots$$

Here $\gamma^{(i+1)}$ is the inverse of $\gamma^{(i)}$ for $i = 1, 3, 5$. The number $\gamma^{(3)}$ is an approximation to $\gamma(\eta_1)$ and $\gamma^{(5)}$ is an approximation to $\gamma^2(\eta_1)$.

The minimum polynomial is

$$F(Y) = Y^6 - 10675494700619930593782Y^5$$
$$-173690986929614172042800423512161Y^4$$
$$-329339405212412219248997455956670633604372Y^3$$
$$-173690986929614172042800423512161Y^2$$
$$-10675494700619930593782 + 1.$$  

The minimum polynomial of $\varepsilon$ is

$$G(Y) = Y^6 + 23392529309499872876162751357786Y^5$$
$$-72166037414606434407109788942932928472329083234$$
$$913Y^4$$
$$-547210427497253920042364578762595732774592939740$$
$$725519246576052Y^3$$
$$-72166037414606434407109788942932928472329083234$$
$$913Y^2$$
$$+23392529309499872876162751357786Y + 1.$$  

and the minimum polynomial of its cube roots is

$$H(Y) = Y^6 + 28596413658Y^5 - 89436172566759393Y^4 - 8179337463$$
$$87389632436Y^3$$
$$-89436172566759393Y^2 + 28596413658Y + 1.$$  

It divides $G(Y^3)$. Similarly, the minimum polynomial of $\varepsilon'$ is given by

$$G'(Y) = Y^6 + 721660374146064344047705360119833055596166331877$$
$$130Y^5$$
$$-1280063596371034895331917342401311189287121791883$$
$$3759541688955207285148540737850055071600481Y^4$$
$$-52079372121390950174909614792200103729072388176$$
$$174535537311325933525723397957771476778118358185283604Y^2$$
$$-1280063596371034895331917342401311189287121791883$$
$$3759541688955200147285148540737850055071600481Y^2.$$
Finally, the polynomial $H'(Y)$, minimum polynomial of $\sqrt[9]{9}$ is equal to
\[
H'(Y) = Y^6 + 383754Y^5 - 28596797409Y^4 - 204459959828Y^3 \\
-28596797409Y^2 + 383754Y + 1.
\]
It divides $G'(Y^9)$.

5. Results

We have computed the Iwasawa modules $C$ for all quadratic fields $\mathbb{Q}(\sqrt{f})$ of conductor $f < 10000$ with $f \not\equiv 1 \pmod{3}$. In this section we present the numerical results.

First of all, in every case $C$ turns out to be finite. This implies that the sequence of class groups $A_n$ stabilizes. In other words, the projective limit
\[
\lim_{\rightarrow} A_n
\]
is finite. Equivalently:

**THEOREM 5.1.** For all quadratic fields $\mathbb{Q}(\sqrt{f})$ of conductor $f < 10000$ with $f \not\equiv 1 \pmod{3}$ the Iwasawa invariants $\lambda$ associated to the cyclotomic $\mathbb{Z}_3$-extension of $\mathbb{Q}(\sqrt{f})$ are zero.

For any real quadratic field of conductor $f \not\equiv 1 \pmod{3}$ with $A_0 = 0$, i.e. with class number not divisible by 3, the Iwasawa module $C$ is trivial. This is an easy consequence of Nakayama’s Lemma.

There are 144 real quadratic fields of conductor $f < 10000$ with $f \not\equiv 1 \pmod{3}$ that have $A_0 \neq 0$. In these cases $C \cong \Lambda/I$ for some non-trivial $\Lambda$-ideal $I$. In 110 cases we found that $I$ is equal to the maximal ideal $m = (T, 3)$ of $\Lambda$. In these cases all groups $A_n, B_n$ and $C_n$ have order 3 and all maps $A_m \twoheadrightarrow A_n$ are zero ($n > m$). Splitting the cases $f \equiv 0, 2 \pmod{3}$ we have $I = m$ in 45 out of 54 cases when $f \equiv 0 \pmod{3}$ and in 65 out of 90 cases when $f \equiv 2 \pmod{3}$.

The remaining 34 cases are listed in the table below. In the first column the $\Lambda$-ideal $I$ for which $C \cong \Lambda/I$ is given. In the second column the group structure of $C$ is given; this can be deduced easily from the ideal $I$ in column 1. By $a_1 \times a_2 \times \cdots \times a_t$ we indicate the group $\mathbb{Z}/a_1\mathbb{Z} \times \mathbb{Z}/a_2\mathbb{Z} \times \cdots \times \mathbb{Z}/a_t\mathbb{Z}$. In column 3 we have listed the level $n_0$ where stabilization occurs: $C_n = C_{n_0}$ for all $n \geq n_0$. By Corollary 2.6 these entries can also be deduced easily from the ideals in column 1. The remaining columns contain the conductors of the quadratic fields and various frequencies.
Table 5.2.

</table>

The very first entry of Table 5.2 contains the only three cases where $C/T C$ has order 9. In these cases stabilization happens to occur at level $n_0 = 0$. In the remaining 31 cases $C/T C$ has order 3. Using Corollary 2.6 it is easy to figure out the behaviour of the class groups $A_n$ and the maps $A_n \to A_{n'}$ in the $\mathbb{Z}_3$-extension of $\mathbb{Q}(\sqrt{f})$. The groups $A_n$ "grow" and "become" isomorphic to $A_{n_0}$ when $n \geq n_0$; the maps $A_n \to A_{n'}$ are zero when the difference $n' - n$ is sufficiently large. We only discuss the last entry of the table as an example.

Let $F = F_0 = \mathbb{Q}(\sqrt{5529})$. In this case

\[
C_0 = \frac{C}{TC} \cong \Lambda/(T, T^2 - 3, 9) = \Lambda/(T, 3) \cong \mathbb{Z}/3\mathbb{Z},
\]

\[
C_1 = \frac{C}{\omega_1 C} \cong \Lambda/(T^3 + 3T^2 + 3T, T^2 - 3, 9) = \Lambda/(3T, T^2 - 3, 9)
\cong \mathbb{Z}/9\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z},
\]

\[
C_2 = \frac{C}{\omega_2 C} \cong \Lambda/(\omega_2, T^2 - 3, 9) = \Lambda/(T^2 - 3, 9) \cong \mathbb{Z}/9\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z}.
\]

The last line follows from the fact that $\omega_2 = (1 + T)^9 - 1$ is contained in the ideal $I = (T^2 - 3, 9)$. Stabilization of the groups $C_n$ occurs at level $n = 2$. We have that $C_n = C_2$ for $n \geq 2$.

By Corollary 2.6 the class groups $A_n$ are dual to $C[\omega_n]$. It is easy to see that

\[
A_0 \cong \mathbb{Z}/3\mathbb{Z},
\]

\[
A_1 \cong \mathbb{Z}/9\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z},
\]

\[
A_n \cong \mathbb{Z}/9\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z}, \quad \text{for } n \geq 2.
\]

The kernels of the maps $j_{n,n'} : A_n \to A_{n'}$ are dual to $(C/N_{n,n'}C)[\omega_n]$. For all $n' \geq n + 2$, the maps $j_{n,n'}$ are zero. For $n \geq 1$ the maps $j_{n,n+1}$ have kernels isomorphic to $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$. Finally, $j_{0,1}$ is the zero map.
