CURL BOUNDS GRAD ON SO(3)

PATRIZIO NEFF\textsuperscript{1} AND INGO MÜNCH\textsuperscript{2}

\textbf{Abstract.} Let $F^p \in \text{GL}(3)$ be the plastic deformation from the multiplicative decomposition in elasto-plasticity. We show that the geometric dislocation density tensor of Gurtin in the form Curl\textsuperscript{$\#$}$(F^p)$ applied to rotations controls the gradient in the sense that pointwise

\[ \forall R \in C^1(\mathbb{R}^3, SO(3)) : \|\text{Curl}[R] \cdot R^T\|_{\mathbb{M}^{3 \times 3}} \geq \frac{1}{2} \|\text{Grad}[R]\|_{\mathbb{M}^{27}}. \]

\[ \forall A \in C^1(\mathbb{R}^3, so(3)) : \|\text{Curl}[A]\|_{\mathbb{M}^{3 \times 3}} \geq \frac{1}{2} \|\text{Grad}[A]\|_{\mathbb{M}^{27}} = \|\nabla axl[A]\|_{\mathbb{M}^{9}}. \]

1. INTRODUCTION

We show an extension to the Lie-group SO(3) of proper rotations of the following result for linearized kinematics: the operator Curl\textsuperscript{$\#$} (curl arranged row wise) applied to elements of the Lie-algebra of skew-symmetric matrices so(3) already controls all partial derivatives of these matrices. While in general, the operator Curl\textsuperscript{$\#$} cannot control the full gradient since Curl\textsuperscript{$\#$} has 9 independent entries but Grad = D has 27 independent entries, it does so on so(3), since they have only 3 independent components such that taking Grad gives 9 independent entries making the relation between Curl\textsuperscript{$\#$} and Grad invertible.

Such a result can at least be traced back implicitly to Nye [26], who investigated infinitesimal rotations of the crystal lattice due to dislocation motion [11,19,22,23]. He showed for small plastic deformations and zero elastic strains that

\[ -\text{Curl}[\text{skew}[\varepsilon^p]] = (\nabla axl[\text{skew}[\varepsilon^p]])^T - \text{tr}[(\nabla axl[\text{skew}[\varepsilon^p]])^T] I, \quad (1.1) \]

where $\varepsilon^p \in C^1(\Omega, \mathbb{M}^{3 \times 3})$ is the *non-symmetrical infinitesimal plastic distortion* with $\Omega \subset \mathbb{R}^3$ the reference configuration. Here, for second order tensors $\text{skew}[X] := \frac{1}{2}(X - X^T)$, $\mathbb{I}$ is the identity tensor, $\|X\|^2 = \sum_i X_{ii}$, $\text{tr}[X]$ the trace, the axial vector $\text{axl}[A]$ is defined such that $A \cdot v = \text{axl}[A] \times v$ for all $A \in \mathfrak{so}(3)$ and $v \in \mathbb{R}^3$, see also (2.6) and $\nabla \varphi$ is the Jacobian-matrix. With $A : B$ we denote simple contraction, with $A : B$ double contraction. See Section 4 for the proof and background of (1.1). Abbreviating $A = \text{skew}[\varepsilon^p] \in C^1(\Omega, \mathfrak{so}(3))$ one deduces

$$-\text{Curl}_2[A] = (\text{axl}[A])^T - \text{tr}[(\text{axl}[A])^T] \mathbb{I} \iff \nabla \text{axl}[A] = -\text{Curl}_2[A] + \frac{1}{2} \text{tr}[(\text{Curl}_2[A])^T] \mathbb{I},$$

(1.2)

which leads to, cf. (4.9)

$$\forall A \in C^1(\mathbb{R}^3, \mathfrak{so}(3)) : \|\text{Curl}_2[A]\|_{\mathbb{M}^{3 \times 3}}^2 \geq \frac{1}{2} \|DA\|_{\mathbb{R}^{3 \times 3}}^2 = \|\nabla \text{axl}[A]\|_{\mathbb{R}^3}^2,$$

(1.3)

in turn implying infinitesimal rigidity (1.7). Recall also the definition of the curl of displacements $u \in C^1(\Omega, \mathbb{R}^3)$ and the relation to the infinitesimal rotations skew $\nabla[u]$

$$\text{curl}[u] := \nabla \times u = 2\text{axl}[\text{skew}[\nabla u]].$$

(1.4)

The modern theory of finite plasticity is based on the Kröner, Lee, Kondo, Bilby [2, 14, 17, 20] multiplicative decomposition $F = F^e \cdot F^p$ of the deformation gradient $F = \nabla \varphi$ into structural elastic and plastic components. In single crystal plasticity $F^p$ represents the deformation solely resulting from the formation of defects such as dislocations while $F^e$ is due to elastic stretch and elastic rotation of the lattice. In general, $F^e$ and $F^p$ have not the form of a Jacobian matrix, they are incompatible, i.e. $\text{Curl}_2[F^e], \text{Curl}_2[F^p] \neq 0$, a property related to the formation of dislocations. The most general stored defect energy, measuring the incompatibility in $F^p$, which is invariant under a compatible change in the reference configuration [4, 21, 29, 31] is expressible in the geometrical dislocation density tensor $G = \frac{1}{\text{det}[F^p]} \text{Curl}_2[F^p] \cdot (F^p)^T$ which, for $R \in \mathfrak{so}(3)$, reduces to $G = \text{Curl}_2[R] \cdot R^T$. For the necessary background and more references on dislocations, plasticity and microstructures we refer to [1, 4, 5, 27, 28].

Another motivation comes from rigidity results [12, 30] in the spirit of Liouville-type theorems, saying that if the gradient of a deformation is locally a rotation it must be a constant rotation together with a constant translation or more precisely

$$\varphi \in W^{1,\infty}(\Omega, \mathbb{R}^n), \quad \nabla \varphi(x) \in \text{SO}(n) \text{ a.e. } \Rightarrow \nabla \varphi = R = \text{const.} \iff \varphi(x) = R \cdot x + b.$$

(1.5)

A quantized version of this fact has been given recently in [8]. They show that for bounded $\Omega \subset \mathbb{R}^3$ with Lipschitz boundary and $\varphi \in W^{1,2}(\Omega, \mathbb{R}^3)$ there exists a positive constant $C(\Omega)$ and a constant rotation $R$ such that

$$\int_{\Omega} \|\nabla \varphi - R\|^2 \, dx \leq C(\Omega) \int_{\Omega} \text{dist}^2(\nabla \varphi, \text{SO}(3)) \, dx.$$

(1.6)

The respective infinitesimal rigidity result is standard in the treatment of linear elasticity and Korn’s inequality, e.g. [24]. It amounts to

$$u \in W^{1,2}(\Omega, \mathbb{R}^3), \quad \nabla u(x) + \nabla u(x)^T = 0 \iff \nabla u(x) \in \mathfrak{so}(3) \iff \nabla u(x) = A = \text{const.} \iff u(x) = A \cdot x + b,$$

(1.7)
where $A \in \mathfrak{so}(3)$ and $b \in \mathbb{R}^3$ are constant. Since from \sym{\nabla u(x)} = 0 it follows \nabla u(x) = A(x) \in \mathfrak{so}(3) the result (1.7) would follow by applying Curl$_2$ on both sides and using that Curl$_2$ bounds DA on \mathfrak{so}(3) due to (1.3). As a consequence of (1.5) it is known that for smooth, simply connected domains $\Omega \subset \mathbb{R}^3$ and $R \in C^1(\Omega, \mathfrak{so}(3))$

$$0 = \text{Curl}_2[R(x)] \iff R = \nabla \varphi \in \mathfrak{so}(3) = \text{const.} \iff DR = 0,$$

(1.8)

thus showing that Curl$_2[R] = 0 \iff DR = 0$. Obviously, \|Curl$_2[R]\|_{\mathcal{M}^{3 \times 3}}^2 \leq 2 \|\text{DR}\|_{\mathbb{R}^{27}}^2$ by Young’s inequality for all $R \in \mathcal{M}^{3 \times 3}$. The precise relation between Curl$_2$ and Grad = D on SO(2) is easily understood in terms of the representation with one rotation angle $\vartheta : \Omega \subset \mathbb{R}^2 \mapsto \mathbb{R}$

$$R(x, y) = \begin{pmatrix} \cos \vartheta(x, y) & \sin \vartheta(x, y) \\ -\sin \vartheta(x, y) & \cos \vartheta(x, y) \end{pmatrix} \in \text{SO}(2).$$

(1.9)

One checks that

$$\|\text{Curl}_2[R(x, y)]\|_{\mathbb{R}^2}^2 = (|\cos \vartheta_y - (\sin \vartheta)_x|^2 + |\cos \vartheta_y - (\cos \vartheta)_x|^2)$$

$$= \|\nabla \vartheta(x, y)\|_{\mathbb{R}^2}^2 \leq \frac{1}{2} \|\text{DR}\|_{\mathbb{R}^2}^2,$$

(1.10)

which led us to surmise that for three-space dimensions

$$\exists c^+ > 0 \quad \forall R \in C^1(\mathbb{R}^3, \text{SO}(3)) : \quad \|\text{Curl}_2[R]\|_{\mathcal{M}^{3 \times 3}} \geq c^+ \|\text{DR}\|_{\mathbb{R}^{27}}.$$

(1.11)

This is what we will prove in this note with $c = \frac{1}{2}$. In terms of the geometrical dislocation density tensor $G = \text{Curl}_2[R] \cdot R^T$ we observe that \|Curl$_2[R]\|_{\mathcal{M}^{3 \times 3}} = \|\text{Curl}_2[R] \cdot R^T\|_{\mathcal{M}^{3 \times 3}}$ by the invariance of the euclidean norm under SO(3). The non-trivial implication in (1.5) is a simple consequence of (1.11).

It may be that this result is known to experts in the theory of differential geometry. However, we have been unable to find a reference for it and therefore provide a direct proof herein. Let us sketch our method of proof: we use two times that for orthogonal matrices $R^T \cdot R = \mathbb{I}$. The first time we take partial derivatives in fixed $j$-direction and conclude that

$$0 = \partial_j[\mathbb{I}] = \partial_j \left[ R^T \cdot R \right] = (\partial_j R)^T \cdot R + R^T \cdot \partial_j R \Rightarrow$$

$$(R^T \cdot \partial_j R) \in \mathfrak{so}(3), \quad j = 1, 2, 3,$$

(1.12)

giving rise to a second order curvature measure $\tilde{\mathcal{K}} \in \mathcal{M}^{3 \times 3}$ with nine independent components, while the second time we apply the operator Curl$_2$:

$$0 = \text{Curl}_2[R^T \cdot R] \Rightarrow 0 = L_R(\text{DR}) + R^T \cdot \text{Curl}_2[R],$$

(1.13)

relating the Curl$_2[R]$ with nine independent entries to the full gradient DR. Carefully combining both results establishes the claim.

2. Preliminary definitions

Let us introduce two different arrangements of the operator Curl on second order tensors $\mathcal{M}^{3 \times 3}$. Let $X \in C^1(\Omega, \mathcal{M}^{3 \times 3})$ with $X_1, X_2, X_3$ the rows of $X$. Then, for the first arrangement, Curl$_2$ is defined row wise as in [21,31] such that

$$\text{Curl}_2[X(x_1, x_2, x_3)] = \begin{pmatrix} \text{curl}[X_1(x_1, x_2, x_3)] \\ \text{curl}[X_2(x_1, x_2, x_3)] \\ \text{curl}[X_3(x_1, x_2, x_3)] \end{pmatrix} \in \mathcal{M}^{3 \times 3}.$$

(2.1)
The second arrangement is defined through \( \text{Curl}_2[X] := (\text{Curl}_1[X])^T \) and corresponds to Gurtin's definition \([9, 10]\) of the Curl-operator on matrices. For \( X, Y \in C^1(\Omega, M^{3 \times 3}) \) it holds

\[
\text{Curl}_2[X \cdot Y] = L_Y(DX) + X \cdot \text{Curl}_2[Y] \in M^{3 \times 3},
\]

where \( L_Y : \mathbb{R}^{27} \rightarrow M^{3 \times 3} \) is a linear mapping at given \( Y \), arranging all first partial derivatives in \( DX \) of \( X \) in the correct way \([25]\). Let us apply (2.2) to \( R^T \cdot R = \mathbb{I} \). We get

\[
0 = \text{Curl}_2[\mathbb{I}] = \text{Curl}_2[R^T \cdot R] = L_R(D(R^T)) + R^T \cdot \text{Curl}_2[R] = \tilde{L}_R(DR) + R^T \cdot \text{Curl}_2[R],
\]

with \( \tilde{L}_R : \mathbb{R}^{27} \rightarrow M^{3 \times 3} \), linear in \( DR \). Hence

\[
R^T \cdot \text{Curl}_2[R] = -\tilde{L}_R(DR).
\]

We need also to introduce the canonical identification of \( \mathbb{R}^3 \) with \( \mathfrak{so}(3) \). For

\[
A = \begin{pmatrix} 0 & -a_3 & a_2 \\ a_3 & 0 & -a_1 \\ -a_2 & a_1 & 0 \end{pmatrix} \in \mathfrak{so}(3)
\]

we define \( \text{axl} : \mathfrak{so}(3) \hookrightarrow \mathbb{R}^3 \) and \( \text{anti} : \mathbb{R}^3 \rightarrow \mathfrak{so}(3) \) through

\[
\text{axl} \begin{pmatrix} 0 & -a_3 & a_2 \\ a_3 & 0 & -a_1 \\ -a_2 & a_1 & 0 \end{pmatrix} = \begin{pmatrix} a_1 \\ a_2 \\ a_3 \end{pmatrix}, \quad A_{ij} = \sum_{k=1}^3 -\epsilon_{ijk} (\text{axl}[A])_k =: \text{anti}(\text{axl}[A])_{ij},
\]

\[
A \cdot v = \text{axl}[A] \times v, \quad \forall v \in \mathbb{R}^3, \quad (\text{axl}[A])_k = \sum_{i,j=1}^3 \frac{1}{2} \epsilon_{ijk} A_{ij},
\]

where \( \epsilon_{ijk} \) is the totally antisymmetric third order permutation tensor

\[
\epsilon_{ijk} = \begin{cases} +1 & \text{even permutation} \\ 0 & \text{two identical indices} \\ -1 & \text{odd permutation}. \end{cases}
\]

Observe that for the corresponding euclidean vector- and matrix-norms one has for \( A \in \mathfrak{so}(3) \subset M^{3 \times 3} \)

\[
2\|\text{axl}[A]\|_{\mathbb{R}^3} = \|A\|_{M^{3 \times 3}}^2, \quad \|D[A]\|_{M^{3 \times 3}}^2 = 2 \|\nabla \text{axl}[A]\|_{\mathbb{R}^9}^2.
\]

Let us now take partial derivatives of \( R^T \cdot R = \mathbb{I} \). This leads to, \( cf. \) (1.12)

\[
R^T \cdot \partial_j R \in \mathfrak{so}(3), \quad j = 1, 2, 3,
\]

and we may look at the axial representation \( k^j \)

\[
k^j = \text{axl}[R^T \cdot \partial_j R] \in \mathbb{R}^3, \quad j = 1, 2, 3,
\]

which defines the second order curvature tensor

\[
\hat{R} = -(k^1[k^2[k^3]] \in M^{3 \times 3},
\]
with \( k^j \) arranged in columns. Note also that
\[
\|\hat{K}\|_{\mathbb{M}^{3 \times 3}}^2 = \sum_{i=1}^3 \|k^i\|_{\mathbb{R}^3}^2 = \sum_{i=1}^3 \|\text{axl}(R^T \cdot \partial_i R)\|_{\mathbb{R}^3}^2 = \sum_{i=1}^3 \frac{1}{2} \|R^T \cdot \partial_i R\|_{\mathbb{M}^{3 \times 3}}^2
\]

It is basic to reconstruct all partial derivatives in \( D\mathbf{R} \) from \( \hat{\mathbf{R}} \), provided that \( \mathbf{R} \) is known. To see this, write for \( i = 1, 2, 3 \)
\[
[D\mathbf{R}]_i := \partial_i \mathbf{R} = \mathbf{R} \cdot R^T \cdot \partial_i \mathbf{R} = \mathbf{R} \cdot \text{anti}(\text{axl}(R^T \cdot \partial_i \mathbf{R})) = -\mathbf{R} \cdot \text{anti}(k^i) \in \mathbb{M}^{3 \times 3},
\]

hence, \( D\mathbf{R} \in \mathbb{R}^{27} \) may be reconstructed with the help of a mapping \( Z_R : \mathbb{M}^{3 \times 3} \mapsto \mathbb{R}^{27} \), linear at given \( R \in \text{SO}(3) \), with
\[
Z_R(\hat{\mathbf{R}}) = D\mathbf{R}.
\]

Inserting this relation into (2.4) we obtain
\[
R^T \cdot \text{Curl}_L[R] = -\tilde{L}_R(Z_R(\hat{\mathbf{R}})).
\]

Observe that the composition mapping \( \tilde{L}_R.Z_R : \mathbb{M}^{3 \times 3} \mapsto \mathbb{M}^{3 \times 3} \) is again linear at given \( R \). If we can show that \( \tilde{L}_R.Z_R \) is invertible for given \( R \), then from (2.15), we can uniquely express the \( \text{Curl}_L \) in terms of the second order curvature tensor \( \hat{\mathbf{R}} \)
\[
[-\tilde{L}_R.Z_R]^{-1}[R^T \cdot \text{Curl}_L[R]] = \hat{\mathbf{R}}.
\]

3. Detailed computation in index notation

We will show now that the composition mapping \( \tilde{L}_R.Z_R \) in (2.16) is indeed invertible for given \( R \). In order to do so we switch to index notation and use \( \text{Curl}_L \) instead of \( \text{Curl}_L \) (see (2.1)) without compromising the result. Summation over repeated indices is understood and we use orthogonal basis elements making the distinction between co- and contravariant bases obsolete. In this section we distinguish also between symbolic (bold) and component notation of tensors, e.g. \( \mathbf{R} = R_{ab} e_a \otimes e_b \). Since \( \text{Grad}[\mathbf{R}] = D\mathbf{R} \) is a third order tensor, while \( \text{Curl}_L[R] \) is a second order tensor we will use first the orthogonality relation \( R^T \cdot \mathbf{R} = \mathbb{I} \) for rotations in order to map the third order gradient tensor into a second order curvature tensor \( \hat{\mathbf{R}} \), as already alluded too above.

3.1. The gradient of a rotation and the 2nd order curvature

By taking the partial derivatives in fixed \( j \)-direction of the orthogonality relation \( R^T \cdot \mathbf{R} = \mathbb{I} \) and observing (1.12) we obtained the three \( (j = 1, 2, 3) \) second order antisymmetric tensors
\[
K^j := R^T R_{-,j}, \quad K^j \in \text{so}(3) \subset \mathbb{M}^{3 \times 3}.
\]

The corresponding axial vectors \( k^j := \text{axl}(K^j) \in \mathbb{R}^3 \) have been assembled together in the second order curvature tensor \( \hat{\mathbf{R}} \)
\[
\hat{\mathbf{R}} := -(k^1|k^2|k^3)
\]

\[
= -k^j \otimes e_j = -\text{axl}(K^j) \otimes e_j = -\text{axl}(R^T \cdot R_{-,j}) \otimes e_j = \frac{1}{2} (\epsilon : (R^T \cdot R_{-,j})) \otimes e_j.
\]
In (3.2) we may perceive the mapping between \( \hat{R} \) and the full gradient of \( R \), which can be seen now more clearly again in index notation

\[
\hat{R} := \frac{1}{2} \epsilon_{iab} R_{ac} R_{ab,j} e_i \otimes e_j.
\]  

(3.3)

The linear map connecting the full gradient \( \text{Grad}[R] \) with the second order curvature tensor \( \hat{R} \) reads

\[
\text{Grad}[R] := R_{ab,j} e_a \otimes e_b \otimes e_j = \epsilon_{bik} R_{ak} \hat{R}_{ij} e_a \otimes e_b \otimes e_j,
\]  

(3.4)

and by defining

\[
\hat{Z}_R := \epsilon_{bik} R_{ak} e_a \otimes e_b \otimes e_i = R_{ab} \epsilon_{bik} e_a \otimes e_b \otimes e_i = R \cdot e,
\]  

(3.5)

it can also be rephrased in symbolic notation:

\[
\text{Grad}[R] = Z_R(\hat{R}) = \hat{Z}_R \cdot \hat{R},
\]  

(3.6)

where the dot denotes simple contraction. By inserting (3.3) into (3.4) we verify the expression for \( \hat{Z}_R \):

\[
\text{Grad}[R] = \epsilon_{bik} R_{ak} \hat{R}_{ij} e_a \otimes e_b \otimes e_j = \epsilon_{bik} R_{ak} \left( \frac{1}{2} \epsilon_{icd} R_{jc} R_{fd,j} \right) e_a \otimes e_b \otimes e_j
\]

\[
= \frac{1}{2} \left( \delta_{kc} \delta_{bd} - \delta_{kd} \delta_{bc} \right) R_{ak} R_{jc} R_{fd,j} e_a \otimes e_b \otimes e_j
\]

\[
= \frac{1}{2} \left( R_{fk} R_{fb,j} - R_{fb} R_{fk,j} \right) R_{ak} e_a \otimes e_b \otimes e_j
\]

\[
= \frac{1}{2} \sum_{i,j} R_{ab} \left( R^T \right)_{ki} R_{fb,j} e_a \otimes e_b \otimes e_j = R_{ab} e_a \otimes e_b \otimes e_j.
\]  

(3.7)

3.2. The Curl of the rotation field

As said above, we use the operator Curl, in this part. To present its definition in index notation we write for \( X \in C^1(\Omega, M^{3\times 3}) \)

\[
\text{Curl}_b[X] = (\partial_a e_a) \times (X_{ij} e_i \otimes e_j)^T = (\partial_a e_a) \times (X_{ji} e_i \otimes e_j) = \partial_a \epsilon_{aijk} X_{ji} e_k \otimes e_j
\]

\[
= (\nabla \times (X^T \cdot e_1)) \cdot \nabla \times (X^T \cdot e_2) \cdot \nabla \times (X^T \cdot e_3) = (\text{Curl}_b[X])^T.
\]  

(3.8)

Applying the operator Curl, on the orthogonality relation \( R^T \cdot R = I \) we obtain

\[
0 = \text{Curl}_b[R^T \cdot R] = \nabla \times [(R^T \cdot R)^T] = \nabla \times (R^T \cdot R) = \partial_m \epsilon_{ma} (R^T \cdot R)_{ac} e_b \otimes e_c
\]

\[
= \epsilon_{ma} \partial_m (R_{af} R_{fc}) e_b \otimes e_c (\epsilon_{ma} (R^T)_{af,m} R_{fc} + \epsilon_{ma} R_{fa} R_{fc,m}) e_b \otimes e_c \Rightarrow
\]

\[
\text{Curl}_b[R] \cdot R = (\nabla \times R^T) \cdot R = -\epsilon_{ma} R_{fa} R_{fc,m} e_b \otimes e_c = L_R(\text{Grad}[R]).
\]  

(3.9)

The linear map \( L_R \) defined implicitly in (3.9) would need an extended symbolic notation with which we can, fortunately enough, dispense. The precise definition in index notation

\[
L_R(\text{Grad}[R]) := -\epsilon_{ma} R_{fa} R_{fc,m} e_b \otimes e_c = \epsilon_{ma} R_{fa} (\text{Grad}[R])_{fc,m} e_b \otimes e_c
\]  

(3.10)

will prove to be useful below.
3.3. Combination of the results

Equation (3.9) yields the relation between the Curl (left hand side) and the full gradient of \( \mathbf{R} \) (right hand side). As discussed in Section 3.1, the gradient is completely described by the second order curvature tensor \( \hat{\mathbf{R}} \). Inserting (3.6) in (3.10) we obtain

\[
\text{Curl}_b[\mathbf{R}] \cdot \mathbf{R} = L_R(\text{Grad}[\mathbf{R}])
\]

\[
= \epsilon_{mba} R_{fa} (Z_R (\hat{\mathbf{R}})) f_{c.m} \mathbf{e}_b \otimes \mathbf{e}_c = \epsilon_{mba} R_{fa} (\hat{\mathbf{Z}}_R \cdot \hat{\mathbf{R}}) f_{c.m} \mathbf{e}_b \otimes \mathbf{e}_c
\]

\[
= \epsilon_{mba} R_{fa} (\epsilon_{cik} R_{fk} \hat{\mathbf{R}}_{im}) \mathbf{e}_b \otimes \mathbf{e}_c = \epsilon_{mba} \epsilon_{cik} (R^T)_{af} R_{fk} \hat{\mathbf{R}}_{im} \mathbf{e}_b \otimes \mathbf{e}_c
\]

In view of the invertibility of the right hand side (4.4), we continue by writing

\[
\hat{\mathbf{R}} = \text{Curl}_b[\mathbf{R}] \cdot \mathbf{R} = \frac{1}{2} \text{tr}[\text{Curl}_b[\mathbf{R}] \cdot \mathbf{R}] \parallel
\]

showing (2.16). Note the (more than formal?) coincidence with the relation \( \mathcal{S} = \mathbf{R} - \frac{1}{2} \text{tr}[\mathbf{R}] \parallel \) between the symmetric Einstein curvature tensor \( \mathcal{S} \) and the symmetric Ricci curvature [13] tensor \( \hat{\mathbf{R}} \) in the Einstein field equations of general relativity theory [6,32]. Taking matrix-norms on both sides of \( \text{Curl}_b[\mathbf{R}] \cdot \mathbf{R} = \hat{\mathbf{R}} - \text{tr}[\hat{\mathbf{R}}] \parallel \) leads to

\[
\| \text{Curl}_b[\mathbf{R}] \cdot \mathbf{R} \|_{M^{3 \times 3}} = \| \hat{\mathbf{R}} - \text{tr}[\hat{\mathbf{R}}] \parallel \|_{M^{3 \times 3}} = \| \hat{\mathbf{R}} \|_{M^{3 \times 3}}^2 + (\text{tr}[\hat{\mathbf{R}}])^2
\]

where we used (2.12) and (4.4) to obtain the local inequalities, which is the claim. Note that for \( n = 2 \) space dimensions we reproduce exactly the equality in (1.10).

\[\square\]

Inspection of the proof shows that the estimate is already true for all orthogonal matrices. Counting equations in the cases of higher space dimensions suggests that the result remains true for arbitrary dimensions \( n > 3 \).

\[E.g. \; \text{in SO}(4) \text{ the corresponding gradient of the axial representation has 24 independent components (instead of 9 for SO}(3)) \text{ and the number of independent relations corresponding to taking the Curl is also 24. However, we have not looked at this case in detail.}\]

\[\text{NOTE ADDED IN PROOF}\]

After submitting the paper the authors have been kindly made aware by A. Mielke, S. Müller and S. Conti of an elegant argument that applies to all space-dimensions and which also yields a constant independent of the dimension. We are grateful for this improvement and present their reasoning for the benefit of completeness of the development.

For \( X \in C^1(\mathbb{R}^n, \mathbb{M}^{n \times n}) \) define the Curl in dimension \( n \geq 3 \) as the third order tensor

\[
(\text{Curl}_X(x))_{ijk} = \partial_{x_k} X^{ij}(x) - \partial_{x_j} X^{ik}(x) = X^{ij}_{,k} - X^{ik}_{,j}.
\]

Let \( W \in C^1(\mathbb{R}^n, \mathfrak{so}(n)) \) be a skew-symmetric matrix in dimension \( n \geq 3 \). Then

\[
(\text{Curl}_W(x))_{ijk} = \partial_{x_k} W^{ij}(x) - \partial_{x_j} W^{ik}(x) = W^{ij}_{,k} - W^{ik}_{,j} = W^{ij}_{,k} + W^{ki}_{,j}.
\]
Using the skew-symmetry in the upper two indices of $W$ we may write
\[
(W_{ij}^k - W_{ik}^j) - (W_{ij}^k - W_{ik}^j) + (W_{ik}^j - W_{ij}^k) = W_{ij}^k - W_{ik}^j + W_{jk}^i + W_{ik}^j = 2W_{ik}^j,
\]
from which we infer the pointwise equivalence
\[
2W_{ik}^j(x) = (\text{Curl}(W(x)))_{ijk} - (\text{Curl}(W(x)))_{jik} + (\text{Curl}(W(x)))_{kji},
\]
implying the control of all first partial derivatives of the skew-symmetric matrix $W$ in terms of a control of the Curl of this matrix, independent of the space-dimension $n$.

Consider now $R \in C^1(\mathbb{R}^n, \text{SO}(n))$ and expand in the neighbourhood of 0:
\[
R_\epsilon(x) = R_\epsilon(0 + x) = R_\epsilon(0) + \sum_{k=1}^n \partial_x^k R_\epsilon(0) x_k + o(x) \Rightarrow
\]
\[
(R(0))^T R(x) = \mathbb{I}_n + \sum_{k=1}^n \underbrace{[R(0)^T \partial_x^k R(0)]}_{\in \mathfrak{so}(n)} x_k + o(x).
\]
The first partial derivatives $\partial_x^k R(x)$ are still continuous, hence we may also write
\[
\partial_x^k R(x) = \partial_x^k R(0) + O(x) \Rightarrow
\]
\[
(R(0))^T \partial_x^k R(x) = \underbrace{(R(0))^T \partial_x^k R(0)}_{\in \mathfrak{so}(n)} + O(x).
\]
Here and subsequently we let $o(x), O(x)$ denote the Landau symbols, respectively, i.e.,
\[
\lim_{x \to 0} \frac{o(x)}{x} = 0, \quad \lim_{x \to 0} O(x) = 0.
\]
Since
\[
(\text{Curl}(R(0)^T R(x)))_{ijk} = \partial_x^k [R(0)^T R(x)]^{ij} - \partial_x^i [R(0)^T R(x)]^{jk} = R(0)^T \partial_x^k R(x)^{ij} - R(0)^T \partial_x^j R(x)^{ik}
\]
\[
= R(0)^T [\partial_x^k R(x)^{ij} - \partial_x^i R(x)^{jk}] = R(0)^T (\text{Curl}(R(x)))_{ijk},
\]
we conclude with (3.19) and (3.20) that
\[
R(0)^T (\text{Curl}(R(x)))_{ijk} = (\text{Curl}(R(0)^T R(x)))_{ijk} = R(0)^T [\partial_x^k R(x)^{ij} - \partial_x^i R(x)^{jk}]
\]
\[
= R(0)^T [\partial_x^k R(x)^{ij} - \partial_x^i R(x)^{jk}] + O(x),
\]
such that
\[
(\text{Curl}(R(0)^T R(x)))_{ijk} (x = 0) = R(0)^T [\partial_x^k R(x)^{ij} - \partial_x^i R(x)^{jk}].
\]
Define now
\[ W^{ij}(x) = \sum_{m=1}^{n} [R(0)^T \partial x_m R(0)] x_m \in so(n) \Rightarrow W^{ij}(x) = R(0)^T \partial x_k R(0). \] (3.23)

Thus we have
\[ R(0)^T R(x) = \mathbb{I}_n + \sum_{m=1}^{n} [R(0)^T \partial x_m R(0)] x_m + o(x) = \mathbb{I}_n + W^{ij}(x) + o(x), \] (3.24)

and
\[ (\text{Curl} W)_{jik}(0) = W^{ij}_{,k}(0) - W^{ik}_{,j}(0) = R(0)^T [\partial x_k R(0)^{ij} - \partial x_j R(0)^{ik}]. \] (3.25)

This yields with (3.19) and (3.25)
\[
2\partial x_k [R(0)^T R(x)] = 2W^{ij}_{,k}(0) + O(x)
= (\text{Curl} W)_{jik}(0) - (\text{Curl} W)_{jik}(0) + (\text{Curl} W)_{kji}(0) + O(x)
= (\text{Curl} [R(0)^T R(x)])_{jik}(x = 0) - (\text{Curl} [R(0)^T R(x)])_{jik}(x = 0)
+ (\text{Curl} [R(0)^T R(x)])_{kji}(x = 0) + O(x)
= R(0)^T [(\text{Curl} R(x))_{jik}(x = 0) - (\text{Curl} R(x))_{jik}(x = 0)
+ (\text{Curl} R(x))_{kji}(x = 0) + O(x)],
\] (3.26)

where we have used (3.20) and (3.17). Thus
\[
2R(0)^T \partial x_k [R(x)] = R(0)^T [(\text{Curl} R(x))_{jik}(x = 0) - (\text{Curl} R(x))_{jik}(x = 0)
+ (\text{Curl} R(x))_{kji}(x = 0) + O(x)].
\] (3.27)

Hence, setting \( x = 0 \) we obtain the equivalence
\[
2\partial x_k R(0) = [(\text{Curl} R)_{jik}(0) - (\text{Curl} R)_{jik}(0) + (\text{Curl} R)_{kji}(0)].
\] (3.28)

Since \( R(0) \) is arbitrary this proves the claim. From (3.28) one obtains, without detailed indicial calculation, using only the Cauchy-Schwarz inequality
\[
\forall R \in C^1(\mathbb{R}^n, \text{SO}(n)) : \quad \|\text{Curl} R\|^2_{\mathbb{R}^{n^3}} \geq \frac{4}{9} \|D R\|^2_{\mathbb{R}^{n^3}},
\] (3.29)

with a constant independent of the space-dimension.

**Acknowledgements.** This work was written in the academic year WS05/06 while P.N. held a non-permanent position at FB Mathematik, Universität Duisburg-Essen, Campus Essen. P.N. would like to thank N. Weck, K.J. Witsch, A. Klawonn and J. Schröder for their kind hospitality. P.N has also profited from many helpful discussions over the last years with B. Svendsen on dislocation theory. He is also grateful to A. Mielke for stimulating exchange on the proper formulation of dislocation based plasticity theory. I.M. is grateful to W. Wagner for supervision and support. The result in this paper has been announced at the GAMM-conference, March 2006, Berlin.
4. Appendix: The classical linearized relations

Interpreting Kröner’s [15–18] development in our notation, the dislocation density tensor of the linearized theory $\alpha$ is defined as $\alpha = -\text{Curl}_t[\varepsilon^p]$. Thus one may write

$$-\alpha := \text{Curl}_t[\varepsilon^p] = \text{Curl}_t[\text{sym}[\varepsilon^p]] + \text{Curl}_t[\text{skew}[\varepsilon^p]].$$

Kröner frequently highlighted the relation between Cartan’s torsion tensor [3] of the crystal connection and the dislocation density tensor $\alpha$ [17], p. 292, equation (38), [18], p. 103, on the one hand and Nye’s curvature tensor [17], p. 292, equation (39), on the other hand. According to [18] the relation between Cartan’s torsion and dislocation density tensor has first been established in [2,14]. In the nonlinear theory Kröner writes [17]

$$\alpha_{mlk} := \frac{1}{2} \left( \partial_m F^p_{kl} - \partial_l F^p_{km} \right) = \frac{1}{2} \varepsilon_{mln} (\text{Curl}_t[F^p])_{nk} = \frac{1}{2} \varepsilon_{mln} (\text{Curl}_t[F^p])_{kn},$$

where $\alpha_{mlk}$ is Kröner’s third order dislocation density tensor and $F^p = \mathbb{1} + \varepsilon^p$ is understood. Cartan’s torsion tensor is the anti-symmetric part $\Gamma_{mlk}$ in the first two indices of the (non-symmetric hence non-affine) crystal connection $\Gamma_{mlk}$ defined implicitly through

$$\partial_m(F^p(x) \cdot e_l) = \Gamma_{mlk}(x) \cdot (F^p(x) \cdot e_k),$$

and the relation is $\Gamma_{[ml]k} = \alpha_{mlk}$. To proceed let us note the useful algebraic relations

$$X - \text{tr}[X] \mathbb{1}_n = Y \Leftrightarrow X = Y - \frac{1}{n-1} \text{tr}[Y] \mathbb{1}_n,$$

$$X \in M^{n \times n} : \|X - \text{tr}[X] \mathbb{1}_n\|_{M^{n \times n}} = \|X\|_{M^{n \times n}} + (n - 2) (\text{tr}[X])^2, \quad n \geq 2,$$

which can be seen by straightforward calculation.

In [26] Nye considered the case of a plastically bent single crystal with small angle tilt grain boundaries which are in a state of polygonisation, assumed to be representing a low energy configuration of the crystal. There, the plastic distortion $\varepsilon^p$ consists only of skew-symmetric parts which lead to infinitesimal plastic rotations of the lattice. This means, there is no attendant plastic strain $\text{sym}[\varepsilon^p] = 0$. The skew-symmetric $\varepsilon^p$ locally rotates the lattice (compatible rotations in the sense of Kröner [17]) without causing macroscopic (long range elastic lattice) stresses. Nye defines his curvature tensor in the following way [26]

$$\kappa_{\text{Nye}} := \nabla \text{axl}[\text{skew}[\varepsilon^p]] = \text{Grad}[\text{axl}[\text{skew}[\varepsilon^p]]] = -\frac{1}{2} \varepsilon_{ijk} \varepsilon^p_{kl,j} e_i \otimes e_j,$$

such that $\kappa_{\text{Nye}}$ measures the infinitesimal change in orientation of neighboured lattices. With respect to Nye’s curvature compare also with [7].

The relation between Nye’s curvature $\kappa_{\text{Nye}}$ and Kröner’s definition of the dislocation density tensor of the linearized theory for the restricted case of a skew-symmetric $\varepsilon^p$ is

$$\alpha = \kappa_{\text{Nye}}^T - \text{tr}[^T \kappa_{\text{Nye}}] \mathbb{1}, \quad \kappa_{\text{Nye}} = \alpha^T - \frac{1}{2} \text{tr}[^T \alpha] \mathbb{1}.$$
This linear relation (4.6) is well known [18], p. 103, and is easily established (called Nye’s relation), cf. [4], equation (7.10). We write

\[ \alpha = \kappa_{Nye}^T - \text{tr}[\kappa_{Nye}^T] \mathbb{I} = \left( -\frac{1}{2} \epsilon_{jkl} \epsilon^{p}_{kl,i} + \frac{1}{2} \epsilon_{akl} \epsilon^{p}_{kl,a} \delta_{ij} \right) e_i \otimes e_j \]

\[ = -\frac{1}{2} \left( \delta_{jh} \epsilon_{hkl} \epsilon^{p}_{kl,a} \delta_{ai} - \delta_{ij} \delta_{ha} \epsilon_{hkl} \epsilon^{p}_{kl,a} \right) e_i \otimes e_j \]

\[ = -\frac{1}{2} \left( \delta_{jh} \epsilon_{ai} - \delta_{ij} \delta_{ha} \right) \epsilon_{hkl} \epsilon^{p}_{kl,a} e_i \otimes e_j = \left( -\frac{1}{2} \epsilon_{jab} \epsilon_{hkl} \epsilon^{p}_{kl,a} \right) e_i \otimes e_j \]

\[ = -\epsilon_{jab} \left( \partial_a \frac{1}{2} \epsilon_{hkb} \epsilon^{p}_{kl} \right) e_i \otimes e_j = -\partial_a \epsilon_{abj} \left( (\text{skew}[\epsilon^p])^T \right)_{bi} e_i \otimes e_j \]

\[ = -\left( \nabla \times (\text{skew}[\epsilon^p])^T \right)_{ji} e_i \otimes e_j = -(\text{Curl} [\text{skew}[\epsilon^p]])_{ij} e_i \otimes e_j \]

\[ = -(\text{Curl} [\text{skew}[\epsilon^p]])_{i}^{3} e_i \otimes e_j = -\alpha. \]  

This, together with (4.5) and (4.4) or (4.6) implies that for all \( A \in \mathfrak{so}(3) \) we have

\[ \nabla \text{axl} [A] = -(\text{Curl} [A])^T + \frac{1}{2} \text{tr}[(\text{Curl} [A])^T] \mathbb{I}. \]  

(4.8)

Inverting this relation again with (4.4) and taking the norm on both sides leads with (4.4) to

\[ \| \text{Curl} [A] \|^2_{\mathbb{R}^{3 \times 3}} \geq \| \nabla \text{axl} [A] \|^2_{\mathbb{R}^{3 \times 3}} = \frac{1}{2} \| DA \|^2_{\mathbb{R}^{27}}. \]
