REGULAR CLOSURE OPERATORS AND COMPACTNESS

by G. CASTELLINI

Résumé. Une légère modification de la notion de compacité relativement à un opérateur de fermeture permet d'étendre à la catégorie **TOP** des espaces topologiques divers résultats sur les opérateurs de fermeture réguliers obtenus pour la catégorie **AB** des groupes abéliens. Ainsi les épimorphismes dans les sous-catégories des objets compacts ou compacts-séparés pour un opérateur de fermeture régulier additif sont surjectifs. L'auteur montre aussi que sous certaines conditions sur une sous-catégorie \mathcal{A} de **TOP**, la sous-catégorie engendrée par les objets compacts-séparés pour l'opérateur de fermeture régulier induit sur \mathcal{A} a plusieurs bonnes propriétés normalement obtenues dans des catégories algébriques.

INTRODUCTION

Let \mathcal{A} be a subcategory of a given category \mathcal{X} . The notion of compactness with respect to a closure operator introduced in [2] (cf. also [6] and [7]) seems to yield more interesting results if, in the case of a regular closure operator induced by \mathcal{A} , we restrict our attention to objects of the subcategory only. This allows us to prove that in **AB** and **TOP** the epimorphisms in subcategories of compact and compact-separated objects with respect to a regular closure operator are surjective. Moreover, we are able to extend Theorem 2.6 of [2], in a modified form, to the categories **TOP**, **GR** (groups) and **TG** (topological groups).

Let \mathcal{A} be a subcategory of **TOP**. The behavior of compact Hausdorff topological spaces gives rise to the question of whether the subcategory $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$ of compact-separated objects with respect to $[\]_{\mathcal{A}}$ might form an algebraic category in the sense of [9]. Unfortunately, the answer in general is no and the subcategory **TOP**₁ of **T**₁ topological spaces provides the needed counterexample. As a matter of fact, $\text{Comp}_{\text{TOP}}(\text{TOP}_1) \cap \text{TOP}_1 = \text{TOP}_1$, which is not an algebraic category. However, such a category has coequalizers and the forgetful functor $U: \text{TOP}_1 \rightarrow \text{SET}$ has a left adjoint and preserves regular epimorphisms. In the last section of the paper we show that, under certain assumptions on the subcategory \mathcal{A} , the above mentioned properties of **TOP**₁ are normally satisfied by any subcategory of **TOP** of the form $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$.

All the subcategories will be full and isomorphism closed.
 We use the terminology of [9] throughout.

1 PRELIMINARIES

Throughout we consider a category \mathcal{X} and a fixed class \mathcal{M} of \mathcal{X} -monomorphisms, which contains all \mathcal{X} -isomorphisms. It is assumed that:

- (1) \mathcal{M} is closed under composition
- (2) Pullbacks of \mathcal{M} -morphisms exist and belong to \mathcal{M} , and multiple pullbacks of (possibly large) families of \mathcal{M} -morphisms with common codomain exist and belong to \mathcal{M} .

In addition, we require \mathcal{X} to have equalizers and \mathcal{M} to contain all regular monomorphisms.

One of the consequences of the above assumptions is that there is a uniquely determined class \mathcal{E} of morphisms in \mathcal{X} such that $(\mathcal{E}, \mathcal{M})$ is a factorization structure for morphisms in \mathcal{X} (cf. [5]).

We regard \mathcal{M} as a full subcategory of the arrow category of \mathcal{X} , with the codomain functor from \mathcal{M} to \mathcal{X} denoted by U . Since U is faithful, \mathcal{M} is concrete over \mathcal{X} .

As in [5], by a *closure operator* on \mathcal{X} (with respect to \mathcal{M}) we mean a pair $C = (\gamma, []_C)$, where $[]_C$ is an endofunctor on \mathcal{M} that satisfies $U[]_C = U$, and γ is a natural transformation from $id_{\mathcal{M}}$ to $[]_C$ that satisfies $(id_U)\gamma = id_U$.

Thus, given a closure operator $C = (\gamma, []_C)$, every member m of \mathcal{M} has a canonical factorization

$$\begin{array}{ccc}
 M & \xrightarrow{]m[_C^x} & [M]_C^x \\
 m \searrow & & \downarrow [m]_C^x \\
 & & X
 \end{array}$$

where $[m]_C^x = F(m)$ is called the C -closure of m , and $]m[_C^x$ is the domain of the m -component of γ . Subscripts and superscripts will be omitted when not necessary. Notice that, in particular, $[]_C$ induces an order-preserving increasing function on the \mathcal{M} -subobject lattice of every \mathcal{X} -object. Also, these functions are related in the following sense: if p is the pullback of a morphism $m \in \mathcal{M}$ along some \mathcal{X} -morphism f , and q is the pullback of $[m]_C$ along f , then $[p]_C \leq q$. Conversely, every family of functions on the \mathcal{M} -subobject lattices that has the above properties uniquely determines a closure operator.

Given a closure operator C , we say that $m \in \mathcal{M}$ is C -closed if $]m[_C$ is an isomorphism. An \mathcal{X} -morphism f is called C -dense if for every $(\mathcal{E}, \mathcal{M})$ -factorization (e, m) of f we have that $[m]_C$ is an isomorphism. We call C *idempotent* provided

that $[m]_C$ is C -closed for every $m \in \mathcal{M}$. C is called *weakly hereditary* if $]m[_C$ is C -dense for every $m \in \mathcal{M}$. The class of all C -closed \mathcal{M} -subobjects and the class of all C -dense \mathcal{X} -morphisms will be denoted by \mathcal{M}^C and \mathcal{E}^C , respectively. If m and n are \mathcal{M} -subobjects of the same object X , with $m \leq n$ and m_n denotes the morphism such that $n \circ m_n = m$, then C is called *hereditary* if $n \circ [m_n]_C \simeq n \cap [m]_C$ holds for every $X \in \mathcal{X}$ and for every pair of \mathcal{M} -subobjects of X , m and n with $m \leq n$. C is called *additive* if it preserves finite suprema, i.e., $\sup([m]_C^X, [n]_C^X) \simeq [\sup(m, n)]_C^X$ for every pair m, n of \mathcal{M} -subobjects of the same object X .

For more background on closure operators see, e.g., [1], [3], [4], [5], [8] and [10].

For every (idempotent) closure operator F let $D(F)$ be the class of all \mathcal{X} -objects A that satisfy the following condition: whenever $M \xrightarrow{m} X$ belongs to \mathcal{M} and $X \xrightarrow[r]{s} A$ satisfy $r \circ m = s \circ m$, then $r \circ [m]_F = s \circ [m]_F$. If \mathcal{X} has squares, this is equivalent to requiring the diagonal $A \xrightarrow{\Delta_A} A \times A$ to be F -closed. $D(F)$ is called the class of F -separated objects of \mathcal{X} .

A special case of an idempotent closure operator arises in the following way. Given any class \mathcal{A} of \mathcal{X} -objects and $M \xrightarrow{m} X$ in \mathcal{M} , define $[m]_{\mathcal{A}}$ to be the intersection of all equalizers of pairs of \mathcal{X} -morphisms r, s from X to some \mathcal{A} -object Y that satisfy $r \circ m = s \circ m$, and let $]m[_{\mathcal{A}} \in \mathcal{M}$ be the unique \mathcal{X} -morphism by which m factors through $[m]_{\mathcal{A}}$. It is easy to see that $(\cap []_{\mathcal{A}}, []_{\mathcal{A}})$ forms an idempotent closure operator. Since this generalizes the Salbany construction of closure operators induced by classes of topological spaces, cf. [11], we will often refer to it as the Salbany-type closure operator induced by \mathcal{A} . In [5] such a type of closure operator was called *regular*. To simplify the notation, instead of “[] $_{\mathcal{A}}$ -dense” and “[] $_{\mathcal{A}}$ -closed” we usually write “ \mathcal{A} -dense” and “ \mathcal{A} -closed”, respectively.

Notice that the objects of \mathcal{A} are always $]_{\mathcal{A}}$ -separated (cf. [3]).

$\mathbf{iCL}(\mathcal{X}, \mathcal{M})$ will denote the collection of all idempotent closure operators on \mathcal{M} , pre-ordered as follows: $C \sqsubseteq D$ if $[m]_C \leq [m]_D$ for all $m \in \mathcal{M}$ (where \leq is the usual order on subobjects).

2 BASIC DEFINITIONS AND PRELIMINARY RESULTS

In what follows \mathcal{X} will be a category with finite products and \mathcal{A} will be one of its full and isomorphism-closed subcategories.

Definition 2.1. An \mathcal{X} -morphism $X \xrightarrow{f} Y$ is said to be *\mathcal{A} -closed preserving*, if for every \mathcal{A} -closed \mathcal{M} -subobject $M \xrightarrow{m} X$, in the $(\mathcal{E}, \mathcal{M})$ -factorization $m_1 \circ e_1 = f \circ m$, m_1 is \mathcal{A} -closed.

Definition 2.2. We say that an \mathcal{X} -object X is *\mathcal{A} -compact with respect to \mathcal{A}* if for

every \mathcal{A} -object Z , the projection $X \times Z \xrightarrow{\pi_Z} Z$ is \mathcal{A} -closed preserving.

$\text{Comp}_{\mathcal{X}}(\mathcal{A})$ will denote the subcategory of all \mathcal{A} -compact objects with respect to \mathcal{A} and $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$ will be called the subcategory of compact-separated objects with respect to \mathcal{A} .

Notice that a more general version of Definition 2.2 has been recently introduced by Dikranjan and Giuli in [7]. However, in the context of this paper, since we are only dealing with idempotent closure operators, Definition 2.2 can be seen as a special case of the notion of (C, \mathcal{A}) -compactness that appears in [7]. In our case C is the Salbany-type closure operator induced by the subcategory \mathcal{A} .

A relevant number of examples of (C, \mathcal{A}) -compactness can be found in [6] and [7]. At the end of this section, we will only list some examples where C is the Salbany-type closure operator induced by the subcategory \mathcal{A} .

Notice also that Definition 2.2 only slightly differs from our previous definition of compactness with respect to a closure operator that appeared in [2]. The difference being that we now require that only the projections onto objects of the subcategory \mathcal{A} be \mathcal{A} -closed preserving.

The proofs of the following four results are very similar to the ones in [2], so we omit them.

Proposition 2.3. *If $M \in \text{Comp}_{\mathcal{X}}(\mathcal{A})$ and M is an \mathcal{M} -subobject of $X \in \mathcal{A}$, then M is \mathcal{A} -closed. \square*

Proposition 2.4.

- (a) *Let \mathcal{A} be a subcategory of \mathcal{X} such that $[\]_{\mathcal{A}}$ is weakly hereditary. Then $\text{Comp}_{\mathcal{X}}(\mathcal{A})$ is closed under \mathcal{A} -closed \mathcal{M} -subobjects.*
- (b) *Let \mathcal{A} be a subcategory of \mathcal{X} closed under finite products and \mathcal{M} -subobjects. If $[\]_{\mathcal{A}}$ is weakly hereditary in \mathcal{A} , then $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$ is closed under \mathcal{A} -closed \mathcal{M} -subobjects. \square*

Proposition 2.5. *Suppose that for $e \in \mathcal{E}$, the pullback of $e \times 1$ along any \mathcal{A} -closed subobject belongs to \mathcal{E} . If $X \xrightarrow{f} Y$ is an \mathcal{X} -morphism and (e, m) is its $(\mathcal{E}, \mathcal{M})$ -factorization, then if $X \in \text{Comp}_{\mathcal{X}}(\mathcal{A})$, so does $f(X)$ (where $f(X)$ is the middle object of the $(\mathcal{E}, \mathcal{M})$ -factorization). \square*

For the next result we assume that \mathcal{X} has arbitrary products and that in the $(\mathcal{E}, \mathcal{M})$ -factorization structure of \mathcal{X} , \mathcal{E} is a class of epimorphisms.

Definition 2.6. (Cf. [2, Definition 3.2]). Let \mathcal{A} be a subcategory of \mathcal{X} . The closure operator $[\]_{\mathcal{A}}$ is called compactly productive iff $\text{Comp}_{\mathcal{X}}(\mathcal{A})$ is closed under products.

Proposition 2.7. (Cf. [2, Proposition 3.4]). *Let \mathcal{A} be an extremal epireflective and co-well powered subcategory of \mathcal{X} , such that $[]_{\mathcal{A}}$ is weakly hereditary in \mathcal{A} . If $[]_{\mathcal{A}}$ is compactly productive, then $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$ is epireflective in \mathcal{A} . \square*

We recall the following result from [2]

Proposition 2.8. (Cf. [2, Proposition 1.16]). *Let \mathcal{X} be a regular well-powered category with products and let \mathcal{A} be a subcategory of \mathcal{X} closed under the formation of products and \mathcal{M} -subobjects. Then $[]_{\mathcal{A}}$ is weakly hereditary in \mathcal{A} iff the regular monomorphisms in \mathcal{A} are closed under composition. \square*

In the following examples we see that some nice and well known categories can be seen as compact-separated objects with respect to a regular closure operator. Notice that we take $(\mathcal{E}, \mathcal{M}) = (\text{epimorphisms}, \text{extremal monomorphisms})$.

Examples 2.9.

- (a) Let $\mathcal{X} = \mathbf{TOP}$ and let $\mathcal{A} = \mathbf{TOP}_2$. Then $\text{Comp}_{\mathbf{TOP}}(\mathbf{TOP}_2) \cap \mathbf{TOP}_2 = \mathbf{COMP}_2$ (compact Hausdorff topological spaces).
- (b) Let $\mathcal{X} = \mathbf{TOP}$ and let $\mathcal{A} = \mathbf{TOP}$. Then $\text{Comp}_{\mathbf{TOP}}(\mathbf{TOP}) \cap \mathbf{TOP} = \mathbf{TOP}$.
- (c) Let $\mathcal{X} = \mathbf{TOP}$. For any bireflective subcategory \mathcal{A} of \mathbf{TOP} , we have that $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A} = \mathcal{A}$.
- (d) Let $\mathcal{X} = \mathbf{TOP}$ and let $\mathcal{A} = \mathbf{TOP}_0$. Then $\text{Comp}_{\mathbf{TOP}}(\mathbf{TOP}_0) \cap \mathbf{TOP}_0 = \{\text{b-compact topological spaces}\} \cap \mathbf{TOP}_0$ (cf. [6, Example 3.2]).
- (e) Let $\mathcal{X} = \mathbf{TOP}$ and let $\mathcal{A} = \mathbf{TOP}_1$. Then $\text{Comp}_{\mathbf{TOP}}(\mathbf{TOP}_1) \cap \mathbf{TOP}_1 = \mathbf{TOP}_1$ (cf. Theorem 3.03).
- (f) Let $\mathcal{X} = \mathbf{TOP}$ and let $\mathcal{A} = \mathbf{TOP}_3$ or \mathbf{TYCH} . Then $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A} = \mathbf{COMP}_2$.
- (g) Let $\mathcal{X} = \mathbf{GR}$ and let $\mathcal{A} = \mathbf{AB}$. Then $\text{Comp}_{\mathbf{AB}}(\mathbf{AB}) \cap \mathbf{AB} = \mathbf{AB}$.

3 A-COMPACTNESS AND EPIMORPHISMS

In this section, we will be working in the categories \mathbf{AB} , \mathbf{TOP} , \mathbf{GR} and \mathbf{TG} . In each of these categories \mathcal{M} will be the class of all extremal monomorphisms. Therefore $(\mathcal{E}, \mathcal{M}) = (\text{epimorphisms}, \text{extremal monomorphisms})$.

We start by recalling a result that in a slightly modified form can be found in [2]. The only changes we made were to replace $\text{Comp}(\mathcal{A})$ by $\text{Comp}_{\mathcal{X}}(\mathcal{A})$ and to add the cases $\mathcal{X} = \mathbf{GR}$ and $\mathcal{X} = \mathbf{TG}$. Its proof is not affected by such changes.

Proposition 3.1. (Cf. [2, Proposition 2.5]). *If \mathcal{A} is a subcategory of \mathbf{AB} , \mathbf{TOP} , \mathbf{GR} or \mathbf{TG} and \mathcal{A} is contained in $\text{Comp}_{\mathcal{X}}(\mathcal{A})$, then the epimorphisms in \mathcal{A} are surjective. \square*

A different version of the following theorem for epireflective subcategories of **AB** was proved in [2]. This weakened form for subcategories that are not necessarily epireflective yields an interesting consequence in **AB** and **TOP**.

Theorem 3.2. *Let \mathcal{A} be a subcategory of **AB** (**TOP**). Let us consider the following statements:*

- (a) \mathcal{A} is closed under quotients
- (b) Each \mathcal{M} -subobject of an \mathcal{A} -object is \mathcal{A} -closed
- (c) The projections onto objects of \mathcal{A} are \mathcal{A} -closed preserving
- (d) $\text{Comp}_{\mathcal{X}}(\mathcal{A}) = \mathbf{AB}$ (= **TOP**)
- (e) $\mathcal{A} \subseteq \text{Comp}_{\mathcal{X}}(\mathcal{A})$
- (f) The epimorphisms in \mathcal{A} are surjective.

We have that $(a) \Rightarrow (b) \Rightarrow (c) \Rightarrow (d) \Rightarrow (e) \Rightarrow (f)$. $(f) \not\Rightarrow (a)$.

Proof: $(a) \Rightarrow (b)$. Let $M \xrightarrow{m} X$ be an \mathcal{M} -subobject of $X \in \mathcal{A}$.

For $\mathcal{A} \subseteq \mathbf{AB}$, consider the pair of morphisms $X \xrightarrow[0]{q} X/M$, where q and 0 denote the quotient and the zero-homomorphism, respectively. Clearly $m \simeq \text{equ}(q, 0)$.

For $\mathcal{A} \subseteq \mathbf{TOP}$, consider the pair of continuous functions $X \xrightarrow[c_M]{q} X/M$ where q is the canonical function onto the quotient set X/M , c_M is the constant morphism into $\{M\}$ and X/M has the quotient topology induced by q . We have that $m \simeq \text{equ}(q, c_M)$.

Since $X/M \in \mathcal{A}$ in both cases, we obtain that m is \mathcal{A} -closed.

$(b) \Rightarrow (c)$. Straightforward.

$(c) \Rightarrow (d)$. Straightforward.

$(d) \Rightarrow (e)$. Obvious.

$(e) \Rightarrow (f)$. It follows from Proposition 3.1.

$(f) \not\Rightarrow (a)$. In **AB** take $\mathcal{A} = \mathbf{AC}$ = algebraically compact abelian groups and in **TOP** take $\mathcal{A} = \mathbf{TOP}_1$. \square

Corollary 3.3. *If \mathcal{A} is a subcategory of **AB** or **TOP**, then the epimorphisms in $\text{Comp}_{\mathcal{X}}(\mathcal{A})$ are surjective.*

Proof: From Proposition 2.5, $\text{Comp}_{\mathcal{X}}(\mathcal{A})$ is closed under quotients and by applying Theorem 3.2, we get that the epimorphisms in $\text{Comp}_{\mathcal{X}}(\mathcal{A})$ are surjective. \square

Notice that the above corollary is not a consequence of Proposition 2.9 of [2], since for $F = []_{\mathcal{A}}$, $\text{Comp}_{\mathcal{X}}(\mathcal{A})$ is usually larger than $\text{Comp}(F)$.

Also notice that if we remove item (a) in Theorem 3.2, the implications (b) through (e) hold for subcategories of **GR** and **TG** as well.

Furthermore, the notion of compactness presented in this paper allows us to extend the equivalence of some items in Theorem 2.06 of [2] to epireflective subcategories of **TOP**, **GR** and **TG**, as the following theorem shows.

Theorem 3.4. *Let \mathcal{A} be an epireflective subcategory in either **TOP**, **GR** or **TG**. The following are equivalent:*

- (a) *$\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A} = \mathcal{A}$ and the regular monomorphisms in \mathcal{A} are closed under composition*
- (b) *The epimorphisms in \mathcal{A} are surjective and $[]_{\mathcal{A}}$ is weakly hereditary in \mathcal{A}*
- (c) *Each \mathcal{M} -subobject of an \mathcal{A} -object is \mathcal{A} -closed.*

Proof: (a) \Rightarrow (b). It follows from Propositions 3.1 and 2.8.

(b) \Rightarrow (c). The same proof of e) \Rightarrow f) in Theorem 2.6 of [2] applies here.

(c) \Rightarrow (a). Let us consider the commutative diagram

$$\begin{array}{ccc}
 X \times Z & \xrightarrow{\pi_Z} & Z \\
 m \uparrow & & \uparrow m_1 \\
 M & \xrightarrow[e_1]{} & M_1
 \end{array}$$

where $X, Z \in \mathcal{A}$, (e_1, m_1) is the $(\mathcal{E}, \mathcal{M})$ -factorization of $\pi_Z \circ m$ and M is \mathcal{A} -closed. Clearly, M_1 is \mathcal{A} -closed by hypothesis, so π_Z is \mathcal{A} -closed preserving, i.e., X is \mathcal{A} -compact with respect to \mathcal{A} . Since $[]_{\mathcal{A}}$ is weakly hereditary in \mathcal{A} , from Proposition 2.8 we get that the regular monomorphisms in \mathcal{A} are closed under composition. \square

We next extend, under certain assumptions, the result in Corollary 3.3 to subcategories of the form $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$. This generalizes the fact that the epimorphisms in the category of compact Hausdorff topological spaces are surjective.

Proposition 3.5. *Let \mathcal{A} be an epireflective subcategory of **AB**. Then, the epimorphisms in $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$ are surjective.*

Proof: Let $X \xrightarrow{f} Y$ be an epimorphism in $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$. Then, from Proposition 2.5, $f(X) \in \text{Comp}_{\mathcal{X}}(\mathcal{A})$. Since $Y \in \mathcal{A}$, $f(X) \xrightarrow{i} Y$ is \mathcal{A} -closed (cf. Proposition 2.3). So, $i \simeq \text{equ}(f, g)$, with $Y \xrightarrow{f} Z, Z \in \mathcal{A}$. This implies that $Y/f(X) \in \mathcal{A}$ and again from Proposition 2.5, $Y/f(X) \in \text{Comp}_{\mathcal{X}}(\mathcal{A})$. Let us consider $Y \xrightarrow{q} Y/f(X)$. If $f(X) \neq Y$ we would have that $q \circ f = 0 \circ f$ with $q \neq 0$, which contradicts the fact that f is an epimorphism in $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$. Therefore f is surjective. \square

To show a similar result in **TOP** is a bit more laborious.

Let $Y + Y$ denote the topological sum (coproduct) of two copies of the topological space Y . If M is an extremal subobject of Y , we denote by $Y +_M Y$ the quotient of $Y + Y$ with respect to the equivalence relation $(x, i) \sim (y, j)$, $i, j = 1, 2$ iff either $i \neq j$ and $x = y \in M$ or $(x, i) = (y, j)$ (cf. [4, Definition 1.11]).

Proposition 3.6. *(Cf. [4, Proposition 1.12]). Let \mathcal{A} be an extremal epireflective*

subcategory of **TOP**. For every $Y \in \mathcal{A}$ and for every extremal subobject M of Y , the following are equivalent

- (a) $Y +_M Y \in \mathcal{A}$
- (b) $M = [M]_{\mathcal{A}}$ □

Corollary 3.7. *Let \mathcal{A} be an extremal epireflective subcategory of **TOP**, let $X \xrightarrow{f} Y$ be a \mathcal{A} -morphism and let $M = [f(X)]_{\mathcal{A}}$. Then, $Y +_M Y$ belongs to \mathcal{A} .*

Proof: It follows directly from Proposition 3.6. □

Lemma 3.8. *Let \mathcal{A} be an extremal epireflective subcategory of **TOP** such that $[]_{\mathcal{A}}$ is additive in \mathcal{A} . Then, if $Y \in \text{Comp}_{\mathcal{X}}(\mathcal{A})$, so does $Y + Y$.*

Proof: Let $Z \in \mathcal{A}$ and let $M \xrightarrow{m} (Y + Y) \times Z$ be \mathcal{A} -closed. Notice that $(Y + Y) \times Z$ is homeomorphic to $(Y \times Z) + (Y \times Z)$. Let us call such a homeomorphism i . Thus, $i \circ m$ is the equalizer of two morphisms $(Y \times Z) + (Y \times Z) \xrightarrow{f} T$, $T \in \mathcal{A}$. Let f_1, g_1 and f_2, g_2 denote the restrictions of f and g to the first and the second addend of $(Y \times Z) + (Y \times Z)$, respectively. Let $M_1 \xrightarrow{m_1} Y \times Z$ and $M_2 \xrightarrow{m_2} Y \times Z$ be two morphisms such that $m_1 = \text{equ}(f_1, g_1)$ and $m_2 = \text{equ}(f_2, g_2)$. Then $(i \circ m)(M) = m_1(M_1) + m_2(M_2)$. Let π_Z^1 and π_Z^2 denote the projections onto Z of the first and the second addend of $(Y \times Z) + (Y \times Z)$ and let $[\pi_Z^1, \pi_Z^2]: (Y \times Z) + (Y \times Z) \rightarrow Z$ denote the induced continuous function. If π_Z is the usual projection of $(Y + Y) \times Z$ onto Z , then $([\pi_Z^1, \pi_Z^2]) \circ i = \pi_Z$. Now, $(\pi_Z \circ m)(M) = (([\pi_Z^1, \pi_Z^2]) \circ i \circ m)(M) = ([\pi_Z^1, \pi_Z^2])(m_1(M_1) + m_2(M_2)) = \pi_Z^1(m_1(M_1)) \cup \pi_Z^2(m_2(M_2))$. Since $Y \in \text{Comp}_{\mathcal{X}}(\mathcal{A})$, $\pi_Z^1(m_1(M_1))$ and $\pi_Z^2(m_2(M_2))$ are both \mathcal{A} -closed and so is their union, since $[]_{\mathcal{A}}$ is additive in \mathcal{A} . □

Proposition 3.9. *Let \mathcal{A} be an extremal epireflective subcategory of **TOP** such that $[]_{\mathcal{A}}$ is additive in \mathcal{A} . Let $X \xrightarrow{f} Y$ be an \mathcal{X} -morphism and let $M = [f(X)]_{\mathcal{A}}$. Then, if $Y \in \text{Comp}_{\mathcal{X}}(\mathcal{A})$, so does $Y +_M Y$.*

Proof: From Lemma 3.8, $Y + Y \in \text{Comp}_{\mathcal{X}}(\mathcal{A})$ and from Proposition 2.5, so does $Y +_M Y$. □

Theorem 3.10. *Let \mathcal{A} be an extremal epireflective subcategory of **TOP** such that $[]_{\mathcal{A}}$ is additive in \mathcal{A} . Then the epimorphisms in $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$ are surjective.*

Proof: Let $X \xrightarrow{f} Y$ be an epimorphism in $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$ and let M denote the subspace $[f(X)]_{\mathcal{A}}$. We have that $Y +_M Y \in \text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$ (cf. Corollary 3.7 and Proposition 3.9). From Proposition 2.5, $f(X) \in \text{Comp}_{\mathcal{X}}(\mathcal{A})$ and from Proposition 2.3, $f(X)$ is \mathcal{A} -closed. Thus, $Y +_M Y = Y +_{f(X)} Y$. Let i and j be the left and the right inclusions of Y into $Y + Y$ and let $Y + Y \xrightarrow{q} Y +_{f(X)} Y$ be the quotient map.

Clearly, $q \circ i \circ f = q \circ j \circ f$. If f is not surjective, then we have that $q \circ i \neq q \circ j$. This contradicts our assumption of f being an epimorphism in $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$. \square

4 A-COMPACTNESS AND ALGEBRAIC CATEGORIES

It is well known that COMP_2 , i.e., the category of compact Hausdorff topological spaces, forms an algebraic category in the sense that COMP_2 has coequalizers and the forgetful functor $U: \text{COMP}_2 \rightarrow \text{SET}$ has a left adjoint and preserves and reflects regular epimorphisms (cf. [9]). It is quite natural to wonder whether this result could be extended in TOP to categories of compact-separated objects with respect to a regular closure operator. Unfortunately the subcategory TOP_1 shows that this is not the case. As a matter of fact, $\text{Comp}_{\text{TOP}}(\text{TOP}_1) \cap \text{TOP}_1 = \text{TOP}_1$ (cf. Example 2.9(e)) and TOP_1 is not an algebraic category, since the forgetful functor $U: \text{TOP}_1 \rightarrow \text{SET}$ fails to reflect regular epimorphisms. However, the remaining conditions are all satisfied. We will see that, under certain assumptions on the subcategory \mathcal{A} , TOP_1 outlines the behavior of $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$.

Proposition 4.1. *If \mathcal{A} is an extremal epireflective subcategory of TOP , then $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$ has coequalizers.*

Proof: Let $X \begin{smallmatrix} f \\ \xrightarrow{g} \end{smallmatrix} Y$ be two morphisms in $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$ and let $Y \xrightarrow{q} Q$ be their coequalizer in TOP . From Proposition 2.5, $Q \in \text{Comp}_{\mathcal{X}}(\mathcal{A})$. Since \mathcal{A} is extremal epireflective in TOP , we can consider the reflection $Q \xrightarrow{r} rQ$ of Q in \mathcal{A} . From Proposition 2.5 $rQ \in \text{Comp}_{\mathcal{X}}(\mathcal{A})$. Now, it is easily shown that $Y \xrightarrow{r \circ q} rQ$ is the coequalizer of f and g in $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$. \square

Proposition 4.2. *Let \mathcal{A} be an extremal epireflective subcategory of TOP such that $[]_{\mathcal{A}}$ is additive in \mathcal{A} . Then, the forgetful functor $U: \text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A} \rightarrow \text{SET}$ preserves regular epimorphisms.*

Proof: Let $X \xrightarrow{f} Y$ be a regular epimorphism in $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$. Then, from Theorem 3.10, f is surjective. Therefore $U(f)$ is a regular epimorphism in SET . \square

Proposition 4.3. *Let \mathcal{A} be an extremal epireflective and co-well powered subcategory of TOP . Suppose that $[]_{\mathcal{A}}$ is weakly hereditary in \mathcal{A} and compactly productive. Then, the forgetful functor $U: \text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A} \rightarrow \text{SET}$ has a left adjoint.*

Proof: The case $\mathcal{A} = \{x\}$ is trivial. So, Let $\mathcal{A} \neq \{x\}$. Let X be a set and let X_d be the discrete topological space with underlying set X . Clearly $X_d \in \mathcal{A}$, since \mathcal{A} is an extremal epireflective subcategory of TOP . Let βX be the \mathcal{A} -dense-reflection of X_d into $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$ (cf. Proposition 2.7) and let $X_d \xrightarrow{\beta_X} \beta X$ be the reflection

morphism. If $Y \in \text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$ and $X \xrightarrow{f} UY$ is a morphism in **SET**, then $X_d \xrightarrow{g} Y$ such that $U(g) = f$ is continuous. From Proposition 2.7, there exists a unique $\beta X \xrightarrow{f'} Y$ such that $f' \circ \beta_x = g$ (notice that f' is unique because β_x is a \mathcal{A} -epimorphism). Clearly we have that $Uf' \circ U\beta_x = f$. \square

The results in Propositions 4.1, 4.2 and 4.3 can be summarized in the following

Theorem 4.4. *Let \mathcal{A} be an extremal epireflective and co-well powered subcategory of **TOP** such that $[]_{\mathcal{A}}$ is compactly productive, weakly hereditary in \mathcal{A} and additive in \mathcal{A} . Then, $\text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A}$ has coequalizers and the forgetful functor $U: \text{Comp}_{\mathcal{X}}(\mathcal{A}) \cap \mathcal{A} \rightarrow \mathbf{SET}$ has a left adjoint and preserves regular epimorphisms.* \square
