An algorithm for the word problem in $HNN$ extensions and the dependence of its complexity on the group representation

<http://www.numdam.org/item?id=ITA_1981__15_4_355_0>
AN ALGORITHM FOR THE WORD PROBLEM
IN HNN EXTENSIONS AND THE DEPENDENCE OF ITS
COMPLEXITY ON THE GROUP REPRESENTATION (*)

by J. AVENHAUS (¹), K. MADLENER (¹)

Communicated by J. Berstel

Abstract. — A well-known method for solving the word problem of a finite presented group given as
HNN extension $G^* = \langle G, a; aua = \varphi(u), u \in U \rangle$ is to reduce it to the word problem of $G$ by means of an
a-reduction function $[1,3,4]$. It is shown that the complexity of this method depends very strongly on the
representation of $G^*$. For any Grzegorczyk class $\delta_n$, the complexity of the method applied to $G^*$ as
above may be not less than in $\delta_n$, while the method applied to another presentation of $G^*$, $G^* = \langle H, s;
ss = \psi(v), v \in V \rangle$ may be of complexity in $\delta_0$. For a recursively presented group $G^*$ the method applied
to one presentation may not work at all, while applied to another presentation is very easy.

Résumé. — Une méthode bien connue pour résoudre le problème des mots dans un groupe donné
comme extension de HNN, $G^* = \langle G, a; aua = \varphi(u), u \in U \rangle$ est de le réduire au problème des mots dans
$G$ au moyen d'une fonction de a-réduction. On montre que la complexité de cette méthode dépend très
fortement de la représentation de $G^*$. Pour toute classe de Grzegorczyk $\delta_n$, la complexité de la
méthode, appliquée à $G^*$ donné comme ci-dessus peut être dans $\delta_n$, alors que la même méthode,
appliquée à une autre présentation de $G^*$, $G^* = \langle H, s; ss = \psi(v), v \in V \rangle$, peut être de complexité dans
$\delta_0$. Pour un groupe $G^*$ récursivement présenté, la méthode, appliquée à une certaine présentation, peut
ne pas aboutir du tout, alors qu'elle est très facile pour une autre présentation.

1. INTRODUCTION

In order to do effective computations in a group $G$, $G$ is normally given by a set
$S$ of generators and a set $L$ of defining relators. Any group element can then be
represented by a word $w$ in the generators $s \in S$ and their formal inverses $\bar{s}$,$\bar{s} \in S$. The word problem is to decide for any word $w$ whether it represents the unit
element of the group. Its solvability is basic for any effective computation in $G$.

Let $S$ be a set, $S = \{ s^* | s \in S \}$ and $S^*$ the set of words over $S \cup \bar{S}$. We denote by $e$
the empty word, by $\equiv$ the identity of $S^*$ and by $| w |$ the length of the word $w$. Let
$L \subseteq S^*$, then the set of congruence classes $[x]$ of the congruence generated by
$w = e$ for $w \in L \cup \{ s, ss | s \in S \}$ forms a group $G$ under multiplication $[x] \cdot [y] = [xy]$ and
unit element $[e]$. We write $G = \langle S; L \rangle$ for this group.

Any group $H$ is isomorphic to such a group $\langle S; L \rangle$ and we call $\langle S; L \rangle$ a presentation of $H$. We will consider only groups given by presentations with finite $S$, this means finitely generated groups. $\langle S; L \rangle$ is finitely presented (f. p) resp. recursively presented (r. p.), if $L$ is finite resp. recursively enumerable.

If we represent a group element $[x]$ by the word $x$, then the problem whether $[x]=[y]$ -- we write $x=y$ in $G$ in this case-reduces to the word problem $xy^{-1}=e$ in $G$. It is well known that the word problem is unsolvable in general even for f. p. groups, but there are large classes of groups for which it is solvable.

One method for solving the word problem for a class of groups is to use group theoretical structure properties of the groups in the class. This means to use how the groups are built up from smaller groups for reducing the word problem to the word problem of the smaller groups. This is done for instance for solving the word problem in the class of groups with only one defining relator.

The composition of a group out of smaller ones may not be unique, so one may ask whether one decomposition is better than an other one with respect to the complexity of the algorithm for solving the word problem induced by the decomposition.

We will describe algorithms in $G$ by appropriate word functions $f : S^* \rightarrow S^*$ and identify the complexity of the algorithm with the complexity of $f$. In this paper the well known Grzegorczyk classes $\delta_n$ are used to measure the complexity of the algorithms. $\delta_n$ is the smallest class of functions containing the initial functions:

- $\varepsilon : S^* \rightarrow S^*$ constant $e$,
- $R_a : S^* \rightarrow S^*$, $w \rightarrow wa$ for $a \in S \cup \overline{S}$,
- $\pi_i^k : S^{*k} \rightarrow S^*$, $(w_1, \ldots, w_k) \rightarrow w_i$, $1 \leq i \leq k$,

together with the $n$-th Ackermann-function and which is closed under substitution and bounded recursion.

Here, $f$ is derived from the functions $g, h_a$ and $b$ by bounded recursion means that:

$$f(x, e) \equiv g(x), \quad f(x, ya) \equiv h_a(x, y, f(x, y))$$

and:

$$|f(x, y)| \leq |b(x, y)|,$$

for all $x \in S^{*k}, y \in S^*, a \in S \cup \overline{S}$.

The Ackermann-functions are given by:

$$A_1(x, y) \equiv s_1^{s_1+|y|}(s_1 \in S \text{ fixed}),$$
$$A_{n+1}(x, y) \equiv s_1, \quad A_{n+1}(x, ya) \equiv A_n(x, A_{n+1}(x, y)).$$
It can be shown that an unbounded recursion with \( \delta_n \)-functions may lead to an \( \delta_{n+1} \) function. We have \( \delta_n \subseteq \delta_{n+1} \) and the union of all the classes \( \delta_n \) coincides with the class of primitive recursive word functions.

One of the most important tools for the construction of groups with specified properties and for the analysis of algorithmic problems in groups — specially the word problem — is the concept of HNN-extension \([1, 2, 4, 6]\): If \( G \) is a group with isomorphic subgroups \( U, V \) and \( \varphi : U \to V \) an isomorphism then the group:

\[
G^* = \langle G, a; \overline{aua} = \varphi(u), u \in U \rangle,
\]

is called an HNN-Extension of \( G \) with stable letter \( a \).

\( G \) is a subgroup of \( G^* \) \([6]\), so its word problem cannot be harder than that of \( G^* \). We want to reduce the word problem of \( G^* \) to that of \( G \). If \( G = \langle S; L \rangle \), then \( G^* \) is generated by \( S^* := S \cup \{ \overline{a} \} \) and has as defining relators \( L \) together with the relations given above. If \( w \in S^*_n \) has the form \( w \equiv x\overline{au}vy \) with \( u \in U \), then \( w = x\varphi(u)y \) in \( G^* \). A word \( w \in S^*_n \) is \( a \)-reduced, if it does not contain a “pinch” \( \overline{au}, u \in U \) or \( a\overline{v}, v \in V \), as a segment.

A function \( r : S^*_a \to S^*_a \) is an \( a \)-reduction function, if \( r(w) = w \) in \( G^* \) and \( r(w) \) is \( a \)-reduced.

The systematic elimination of pinches leads to an \( a \)-reduction function. More formally we can define an \( a \)-reduction function \( r : S^*_a \to S^*_a \) by:

\[
r(e) \equiv e, \\
r(wc) \equiv r(w)c, \quad c \in S \cup \overline{S}; \\
r(wa) \equiv \begin{cases} 
  x\varphi(u), & w \equiv x\overline{au}, \quad u \in S^*, \quad u \in U, \\
  r(w)a, & \text{else}; 
\end{cases} \\
r(\overline{wa}) \equiv \begin{cases} 
  x\varphi^{-1}(v), & w \equiv x\overline{av}, \quad v \in S^*, \quad v \in V, \\
  r(w)\overline{a}, & \text{else}. 
\end{cases}
\]

By means of an \( a \)-reduction function the word problem of \( G^* \) is reducible to that of \( G \). By \([6]\) we get:

\( w = e \) in \( G^* \) iff \( r(w) \) is \( a \)-free and \( r(w) = e \) in \( G \).

The complexity of this method is the least upper bound of the complexities of \( r \) and of \( G \)'s word problem. In order to compute \( r \) as defined above one has to decide for \( u \in S^* \) whether \( u \in U (u \in V) \) and in the positive case to compute \( \varphi(u) (\varphi^{-1}(u)) \). If this can be done by an \( \delta_n \)-process, then \( r \in \delta_{n+1} \), since \( r \) is defined by recursion with \( \delta_n \)-functions in this case. Let \( G \) have a \( \delta_n \)-decidable word problem, then \( G^* \) has an \( \delta_{n+1} \) - decidable word problem. If in addition \( r \) can be bounded by an \( \delta_n \)-function, it is itself an \( \delta_n \)-function, hence \( G^* \) has \( \delta_n \)-decidable word problem, too. So two questions arise:
(1) **Question:** Is this apparent jump of the complexity from $\mathcal{E}_n$ to $\mathcal{E}_{n+1}$ really possible for all $n$, that is: Given any $n \in \mathbb{N}$, does there exist a f. p. HNN-extension $G^* = \langle G, a; \tilde{a}u\tilde{a} = \varphi(u), u \in U \rangle$ such that the decisions for $U, V$ and the computations of $\varphi, \varphi^{-1}$ are in $\mathcal{E}_n$ but there is no $a$-reduction function in $\mathcal{E}_n$ for $G^*$

(2) **Question:** How does the complexity of the described method for solving the word problem of $G^*$ change if one chooses an other HAW-decomposition $G^* = \langle H, b; \tilde{b}vb = \psi(v), v \in V \rangle$ for the group.

The first question came up to us in studying the complexity of algorithmic problems in one relator groups in [2]: Every one relator group $G = \langle S; p \rangle$ with $|p| < 2n$ can be embedded in a HNN-extension $G^*$ of a one relator group $H = \langle S_0; p_0 \rangle$ with $|p_0| < 2n - 2$. An induction on $n$ gives that $G$ has $\mathcal{E}_n$-decidable word problem. If it could be proved that the jump from $\mathcal{E}_n$ to $\mathcal{E}_{n+1}$ in the reduction for $G^*$ does not occur for some $n$, one would have a bound for the complexity of the word problem for one relator groups independent of the length $|p|$ of the relator. Such bound is not known [2, 5], it is conjectured however that every one relator group has $\mathcal{E}_4$-decidable word problem.

Our goal is to give for $n \geq 4$ examples of groups $G^*$ with a finite presentation $G^* = \langle G, a; aua = \varphi(u), u \in U \rangle$ such that the method gives an $\mathcal{E}_4$-solution of the word problem for $G^*$ and with an other finite presentation $G^* = \langle H, b; \tilde{b}vb = \psi(v), v \in V \rangle$ such that the subgroups are $\mathcal{E}_n$-decidable and the isomorphisms are $\mathcal{E}_n$-computable but for which no $b$-reduction in $\mathcal{E}_n$-exists. These examples were given in [2], without proof. This paper can be viewed as an continuation of [2], but is of independent interest and the knowledge of [2] is not indispensable for this paper.

The examples answer both questions given above. So the method of solving the word problem for a group $G^*$ given as HNN-extension depends very strongly on the HNN-representation chosen for $G^*$. For "bad" decompositions it may be extremely inefficient. If one allows recursively presented HNN-extensions $G^*$ we show that for one representation there may be no recursive reduction function while for an other one there is an $\mathcal{E}_2$-reduction function and the word problem for $G^*$ is $\mathcal{E}_2$-decidable.

2. MAIN RESULTS

In this section we first give an example of r. p. HNN-extension with $\mathcal{E}_2$-decidable word problem, such that no recursive reduction function exists. Then we turn to the more complicated case of finitely presented groups and state the
main results. As usual in the determination of the complexity of algorithmic problems the main technical difficulties are in proving that some naturally given lower bound for the complexity of the problem is sharp. This will occupy most of section 3 of this paper were the proofs are given.

We need some more terminology and concepts from group theory. If \( A \subseteq S^* \), then \( A^{-1} \) is the set \( \{ x^{-1} \mid x \in A \} \). Now \( A^* \) is the set of words in the \( x \in A \cup A^{-1} \), while \( \langle A \rangle \) is the set of words representing elements of the subgroup generated by \( A \): For \( G = \langle S; L \rangle \) and \( A \subseteq S^* \) we have \( w \in \langle A \rangle \) iff there is an \( u \in A^* \) such that \( w = u \) in \( G \). In the computation of a reduction function for an \( HNN \)-extension of \( G \) with a subgroup generated by a set \( A \), we must decide whether a word lies in \( \langle A \rangle \) and in the positive case apply the isomorphism to the word of \( A^* \). For subgroups of the free group this can be done easily if \( A \) is a set of Nielsen reduced words \([6]\). Let \( \rho \) be the free reduction function, then \( A \) is called Nielsen reduced if the following three conditions hold:

1. If \( x \in A \) then \( x^{-1} \notin A \) and \( \rho (x) \equiv x \).
2. If \( x, y \in A \cup A^{-1} \), \( |\rho (xy)| > 0 \) then \( |\rho (xy)| \geq |x| \).
3. If \( x, y, z \in A \cup A^{-1} \), \( |\rho (xy)| > 0 \), \( |\rho (yz)| > 0 \) then:
   \[ |\rho (xyz)| > |x| - |y| + |z| \]

A Nielsen reduced set \( A \) has two advantages: Its elements freely generate the subgroup \( \langle A \rangle \) and the problem \( w \in \langle A \rangle \) is reducible to the problem \( x \in A \).

Now we give our first example. Let \( f : \mathbb{N} \to \mathbb{N} \) be an injective \( \delta_2 \)-function which enumerates a recursively enumerable but not decidable subset of \( \mathbb{N} \). The group:

\[ G^* = \langle a, b, c, d; d^f(a)bc^f(b) = b^f(c)cb^f(a) \mid n \in \mathbb{N} \rangle, \]

is a \( HNN \)-Extension of the free group \( G = \langle a, b, c; \emptyset \rangle \) with stable letter \( d \). There is no computable \( d \)-reduction function \( r \) for \( G^* \), because of \( m \in f(\mathbb{N}) \) iff \( r(d^{f(m)}cb^{f(m)}d) \) is \( d \)-free.

On the other hand another representation for \( G^* \) as a \( HNN \)-extension of a free group is:

\[ G^* = \langle a, b, c, c^f; c^f(a^n)d^f(b^n)c = b^f(c)cb^f(a^n) \mid n \in \mathbb{N} \rangle. \]

Here the stable letter is \( c \), \( U = V \) and the identity is the isomorphism. The set \( \{ a^n d^f(b^n) \mid n \in \mathbb{N} \} \) is Nielsen reduced and \( \delta_2 \)-decidable in \( \langle a, b, c; \emptyset \rangle \). So \( U \) and \( V \) are \( \delta_2 \)-decidable and the definition of paragraph 1 gives a \( c \)-reduction function for \( G^* \) in \( \delta_2 \). This means that the word problem for \( G^* \) is \( \delta_2 \) decidable, though there is no \( d \)-reduction function for the first representation of \( G^* \). Of course similar examples can be constructed for any complexity degree, but notice that the group in this example is not finitely presented.

vol. 15, n°4, 1981
We turn now to the class of finitely presented groups. We define two sequences of groups $G_n$ and $H_n$ which are built up as HNN-extensions. To simplify notations we set $s_0 = b^2$.

$$G_0 = \langle a, b; \emptyset \rangle,$$

$$G_n = \langle G_{n-1}, s_n; \overline{s_n} as_n = \overline{bab}, \overline{s_n} bs_n = s_{n-1} \rangle, \quad n > 0,$$

$$H_0 = \langle b; \emptyset \rangle,$$

$$H_n = \langle H_{n-1}, s_n; \overline{s_n} bs_n = s_{n-1} \rangle, \quad n > 0,$$

where $S = \{ s_n | n > 0 \}$ is an infinite set of letters different from $a, b$. It is easy to see that the groups $H_n$ are all one relator groups.

2.1. Theorem: For any $n \geq 1$:

(a) $G_n$ is a HNN-Extension of $G_{n-1}$ with stable letter $s_n$. There exists a $s_n$-reduction function $r_n \in \mathcal{E}_{n+2}$, but no $s_n$-reduction function lies in $\mathcal{E}_{n+1}$.

(b) $H_n$ is a HNN-extension of $H_{n-1}$ with stable letter $s_n$. There exists a $s_n$-reduction function $p_n \in \mathcal{E}_{n+1}$ and for $n \geq 2$ no $s_n$-reduction function lies in $\mathcal{E}_{n+1}$.

(c) $G_n$ is a HNN-extension of $H_n$ with stable letter $a$ and there exists an $a$-reduction function in $\mathcal{E}_{n+1}$.

(d) Both, $G_n$ and $H_n$, have $\mathcal{E}_{n+1}$-decidable word problems.

We will prove this theorem in paragraph 3.

The groups $G_n$, $H_n$ can be pictured in the following way.

We draw some consequences of the theorem.

2.2. Corollary: For $n \geq 3$ there is a finitely presented HNN-extension $G^* = \langle G, a; \overline{\alphaua} = \varphi(u), u \in U \rangle$ with:

(i) $U$ and $\varphi(U)$ are $\mathcal{E}_n$-decidable subgroups of $G$.

(ii) The isomorphisms $\varphi$ and $\varphi^{-1}$ are $\mathcal{E}_n$-computable.

(iii) There is no $a$-reduction function for $G^*$ in $\mathcal{E}_n$.
2.3. **COROLLARY:** For \( n \geq 3 \) there is a finitely presented HNN-extension:

\[
G^* = \langle G, s; \overline{su} = \varphi(u), u \in U \rangle = \langle H, a; \overline{a}v = \varphi(v), v \in V \rangle,
\]

with:

(i) \( G \) and \( H \) both have \( \mathcal{E}_4 \)-decidable word problem.

(ii) There exists an \( a \)-reduction function for \( G^* \) in \( \mathcal{E}_4 \).

(iii) There is no \( s \)-reduction function for \( G^* \) in \( \mathcal{E}_n \).

(iv) \( G^* \) has \( \mathcal{E}_4 \)-decidable word problem.

These corollaries follow from the proof of theorem 2.1 in paragraph 3. For 2.2 take \( G_{n-1} \) as HNN-extension of \( G_{n-2} \) and for 2.3 take \( G_{n-1} \) as HNN-extension of \( G_{n-2} \) and of \( H_{n-1} \).

### 3. PROOF OF THEOREM 2.1

#### 3.1. **Lemma:** For \( n \geq 1 \) we have:

(a) \( H_n = \langle H_{n-1}, s_n; \overline{s_n}b_s = s_{n-1} \rangle \) is a HNN-extension of \( H_{n-1} \).

(b) \( G_n = \langle H_n, a; \overline{ab}j a = b\overline{s}_j, j = 1, \ldots, n \rangle \) is a HNN-extension of \( H_n \).

(c) \( G_n = \langle G_{n-1}, s_n; \overline{s_n}as_n = \overline{b}ab, \overline{s_n}bs_n = s_{n-1} \rangle \) is a HNN-extension of \( G_{n-1} \).

**Proof:** We have to prove the isomorphism condition for HNN-extensions.

(a) \( \varphi : b \to \overline{s_{n-1}} \) is an isomorphism, since \( \langle b \rangle \) and \( \langle s_{n-1} \rangle \) are free subgroups of \( H_{n-1} \) (notice that \( s_0 = b^2 \)).

(b) The isomorphism is the identity.

(c) Since \( \langle a, b \rangle \) is a free subgroup of rank two of \( G_{n-1} \), it suffices to prove that \( \langle \overline{bab}, \overline{s_{n-1}} \rangle \) is a free subgroup of rank two also. Let \( U_n = \{ s_1 \overline{b}, \ldots, s_n \overline{b} \} \) and \( \omega \in U_n^* \) be freely reduced in the \( (s_j b)^{\pm 1} \). An induction on \( n \) shows:

(i) \( \omega \) is fully reduced, i.e. contains no \( s_i \)-pinches (\( 1 \leq i \leq n \));

(ii) \( \overline{b} \omega b = s^b_n \) in \( H_n \) if \( k = 0 \) and \( \omega = e \);

(iii) \( \omega = b^k \) in \( H_n \) if \( k = 0 \) and \( \omega = e \).

By (i) the subgroup \( \langle U_n \rangle \) of \( H_n \) and hence of \( G_n \) too is freely generated by the \( s_j b \). By (ii) any \( \omega \in \{ \overline{bab}, s_n \}^* \) freely reduced in \( \overline{b}a^{\pm 1}b, s_n^{\pm 1} \) is \( a \)-reduced in \( G_n \).

Hence \( \langle \overline{bab}, s_n \rangle \) is a free subgroup of rank two of \( G_n \). \( \triangle \)

We want to prove that there is no \( s_n \)-reduction function for \( G_n \) in \( \mathcal{E}_n+1 \) but there is an \( s_n \)-reduction function for \( H_n \) in \( \mathcal{E}_4 \). For this we show that the words \( s^i_n \overline{bab} s_n^i \) become very long after \( s_n \)-reduction. In order to measure the increase of the length we introduce functions \( f : \mathbb{N} \to \mathbb{N} \) and \( f_n : \mathbb{N} \to \mathbb{N} (n \geq 0) \) by the following equations.
For $i, n \in \mathbb{N}$ let:

(a) $f(0) = 1$, $f(i+1) = 2^{f(i)}$;
(b) $f_0(i) = 2i + 1$, $f_{n+1}(i) = f_n(i)$ \hspace{1cm} ($f_n$ iterated $i$-times).

Then we get:

3.2. **Lemma:** (a) The function $f$ is a generating function of the arithmetic class $S_4$ and the $f_n$ are generating functions of the classes $S_{n+2}(n \geq 1)$:
(b) Let $x_0 = b$ and $x_{i+1} = s_2 x_i^{-1} s_2 b s_2 x_i s_2 (i \geq 1)$, then $x_i = b^{f(i)}$ in $H_2$.
(c) For $i, n \in \mathbb{N}$, $s_i^i b a b s_i^i = b^{f_n(i)} a b f_n(i)$ in $G_n$.

**Proof:** For (a) see f. i. [7].

(b) By induction on $i$:

$$x_{i+1} = s_2 x_i^{-1} s_2 b s_2 x_i s_2 = s_2 b^{f(i)} s_2 b s_2 b^{f(i)} s_2 = s_2^{f(i)} b s_2^{f(i)} = b^{2f(i)} \text{ in } H_2.$$

(c) By induction on $n, i$:

$$s_{n+1}^{i+1} b a b s_n^i = s_{n+1}^{i+1} b^{f_{n+1}(i)} a b s_n^{i+1} = s_{n+1}^{f_{n+1}(i)} b a b s_n^{f_{n+1}(i)} = b^{f_{n+1}(i)} a b f_{n+1}(i) \text{ in } G_{n+1}. \triangle$$

In the sequel we will use the following abbreviation:

$$k_{n, i} := \begin{cases} b^{f(i)} a b f(i), & i > 0, \\ b^{-i+1} a b^{-i+1}, & i \leq 0. \end{cases}$$

By Lemma 3.2 the following equation holds:

$$k_{n, i} = s_n^i b a b s_n^i \text{ in } G_n \text{ for } n \geq 1 \text{ and } i \geq -n.$$

3.3. **Lemma:** Let $n \geq 1$ and $K_n = \langle k_{n, j} | j \geq -n \rangle \in G_0$.

Then for any $\omega \in G_n$ we have $\omega \in \langle b a b, s_n \rangle$ in $G_n$ iff there are $l, m \geq 0$ and $u \in \{ a, b \}^*$, $u \in K_n$ such that $\omega = s_n^l u s_n^{-m}$ in $G_n$ and $s_n^l u s_n^{-m}$ is $s_n$-reduced.

This means that the decision for $u \in \langle b a b, s_n \rangle$ in $G_n$ is reduced after $s_n$-reduction to the decision $u \in K_n$ in the free group $G_0 = \langle a, b; \emptyset \rangle$.

**Proof:** "$\Rightarrow$" Since $k_{n, j} = s_n^j b a b s_n^j \in \langle b a b, s_n \rangle$, we have $\omega = s_n^l u s_n^{-m} \in \langle b a b, s_n \rangle$ if $u \in K_n$.

"$\Leftarrow$" Let $\omega \in \{ b a b, s_n \}^*$. Because of $s_n k_{n, j} s_n = k_{n, j+1}$ in $G_n$ for $j \geq -n$, we can shift in $\omega$ all $s_n$ to the right and all $s_n$ to the left. This gives a word $v \in \{ k_{n, i} | i \geq 0 \}^*$ with $\omega = s_p^q u s_n^{-q}$ in $G_n (p, q \geq 0)$.

R.A.I.R.O. Informatique théorique/Theoretical Informatics
The word $s_n^p v s_n^{-q}$ may not be $s_n$-reduced. We show by induction on $n$ that the $s_n$-reduction of such a word $s_n^p v s_n^{-q}$ results in a word $s_n^l u s_n^{-m}$ with $u \in K_n$, $l, m \geq 0$. To do this, it suffices to prove that $s_n v s_n \in K_n$, if $v \in K_n$ and $s_n v s_n$ is a $s_n$-pinch.

Notice that the $k_{n,j}$ freely generate $K_n$ in the free group $\langle a, b; \emptyset \rangle = G_0$ because they are Nielsen reduced.

For $n = 1$, if $s_1 v s_1$ is a $s_1$-pinch we have $v \in \langle k_{1,j} | j \geq -1 \rangle$ and $v \in \langle b a b, b^2 \rangle$ in $G_0$. So $v \in \langle k_{1,j} | j \geq 0 \rangle$ and $s_1 v s_1 \in \langle k_{1,j} | j \geq -1 \rangle = K_1$.

For the induction step: If $s_n v s_n$ is a $s_n$-pinch then:

$$v \in \langle k_{n,j} | j \geq -n \rangle \cap \langle b a b, s_{n-1} \rangle.$$  

By the induction hypothesis $v$ cannot contain the factor $k_{n-1,-n} = k_{n,-n}$. We get $v \in \langle k_{n,j} | j \geq -n \rangle$ and $s_n v s_n \in \langle k_{n,j} | j \geq -n \rangle = K_n$. \triangle

With this Lemma we can now prove the existence of a $s_n$-reduction function in $\mathfrak{S}_{n+2}$ for $G_n$.

3.4. Lemma: There is a $s_n$-reduction function $r_n \in \mathfrak{S}_{n+2}$ for $G_n = \langle G_{n-1}, s_n; s_n a s_n = b a b, s_n b s_n = s_n^{-1} \rangle$; but for $n \geq 1$ there is no $s_n$-reduction function for $G_n$ in $\mathfrak{S}_{n+1}$.

Proof: The proof is again by induction on $n$. For $n = 0$, $G_0$ is the free group $\langle a, b; \emptyset \rangle$ and we choose $r_0$ to be the free reduction on $G_0$. We will define $r_n$ such that $r_n(\omega)$ is fully reduced, i.e. contains no $s_i$-pinch as a subword ($1 \leq i \leq n$).

Suppose $r_{n-1} \in \mathfrak{S}_{n+1}$ has been defined. For the definition of $r_n$ we use the following auxiliary function $h_n$:

$$h_n(e) \equiv e,$$

$$h_n(\omega x^\varepsilon) \equiv h_n(\omega) x^\varepsilon, \quad \varepsilon \in \{a, b, s_1, \ldots, s_{n-1}\}, \quad \omega = \pm 1,$$

$$h_n(\omega s_n) \equiv \begin{cases} u \varphi(v), & h_n(\omega) \equiv u s_n v, \quad v \in \langle a, b \rangle, \\ h_n(\omega) s_n, & \text{otherwise}, \end{cases}$$

$$h_n(\omega s_n) \equiv \begin{cases} u \varphi^{-1}(v), & h_n(\omega) \equiv u s_n v, \quad v \in \langle b a b, s_{n-1} \rangle, \\ h_n(\omega) s_n, & \text{otherwise} \end{cases}$$

(in both cases $v$ is $s_n$-free) and put:

$$r_n(\omega) \equiv r_{n-1}(\omega_0) s_n^p r_{n-1}(\omega_1) \ldots s_n^p r_{n-1}(\omega_p),$$

if:

$$h_n(\omega) \equiv \omega_0 s_n^p \omega_1 \ldots s_n^p \omega_p \quad \text{with} \quad \omega_i, \quad s_n \text{-free}.$$
We will have \( r_n \in \mathcal{E}_{n+2} \), if we can prove \( h_n \in \mathcal{E}_{n+2} \). We show that the subgroups \( \langle a, b \rangle \) and \( \langle bab, s_{n-1} \rangle \) of \( G_{n-1} \) are \( \mathcal{E}_{n+1} \)-decidable and the isomorphisms \( \varphi \) and \( \varphi^{-1} \) are \( \mathcal{E}_{n+1} \)-computable. This immediately gives \( h_n \in \mathcal{E}_{n+2} \).

Let \( A_i = \{ a, b, s_1, \ldots, s_i \} \). For \( v \in A_{n-1}^* \) we have \( v \in \langle a, b \rangle \) in \( G_{n-1} \) iff \( r_{n-1}(v) \in \{ a, b \}^* \), since \( r_{n-1}(v) \) is fully reduced.

We get \( \varphi(v) \) if we replace \( a \) by \( bab \) and \( b \) by \( s_{n-1} \) in \( r_{n-1}(v) \). So \( \langle a, b \rangle \) is \( \mathcal{E}_{n+1} \)-decidable and \( \varphi \) is \( \mathcal{E}_{n+1} \)-computable, since \( r_{n-1} \in \mathcal{E}_{n+1} \).

If \( v \in \langle bab, s_{n-1} \rangle \) in \( G_{n-1} \) then \( v = s_{n-1}^l u s_{n-1}^{-m} \) in \( G_{n-1} \), where \( l, m \geq 0 \), \( u \in K_{n-1} \) and \( s_{n-1}^l u s_{n-1}^{-m} \) is \( s_{n-1} \)-reduced by lemma 3.3. Because of \( r_{n-1}(v) = s_{n-1}^l u s_{n-1}^{-m} \) in \( G_{n-1} \), \( r_{n-1}(v) \) and \( s_{n-1}^l u s_{n-1}^{-m} \) must be \( s_{n-1} \)-parallel.

We get \( v \in \langle bab, s_{n-1} \rangle \) in \( G_{n-1} \) if

\[
   r_{n-1}(v) = v_0 s_{n-1} v_1 \cdots s_{n-1} v_l s_{n-1}^{-l} v_{l+1} \cdots s_{n-1} v_{l+m}
\]

and

\[
   \Lambda r_{n-1}(G_{n-1}) s_{n-1}^{-m}) \in K_{n-1}.
\]

Because \( \{ k_{n-1}, j \geq -n+1 \} \) is a Nielsen reduced system of generators for \( K_{n-1} \) in the free group \( G_0 \), it is \( \mathcal{E}_{n+1} \)-decidable whether a word \( x \in A_{n-1}^* \) is in \( K_{n-1} \), and to rewrite it as a word in the \( k_{n-1}, j \). The \( k_{n-1}, j \) can in turn be written as words in \( bab, s_{n-1} \). For the computation of \( \varphi^{-1} \) replace \( bab \) by \( a \) and \( s_{n-1} \) by \( b \) in this word. So the subgroup \( \langle bab, s_{n-1} \rangle \) is \( \mathcal{E}_{n+1} \)-decidable in \( G_{n-1} \) and \( \varphi^{-1} \) is \( \mathcal{E}_{n+1} \)-computable.

We have now proved \( r_n \in \mathcal{E}_{n+2} \). Assume \( r_n' \in \mathcal{E}_{n+1} \) is a \( s_n \)-reduction function for \( G_n \). Since \( r_{n-1} \in \mathcal{E}_{n+1} \) and \( r_n'(s_{n-1}^{-1} bab s_{n-1}) \) is \( s_n \)-free, we can define the words \( \omega_i = r_n'(s_{n-1}^{-1} bab s_{n-1}) (i \geq 0) \) and \( |\omega_i| \) must be bounded by an \( \mathcal{E}_{n+1} \)-function. But of course:

\[
   \omega_i = \overline{b f_i(i)} ab f_i(i) \quad \text{in} \quad G_0,
\]

and \( f_n(i) \) grows faster than any \( \mathcal{E}_{n+1} \)-function. The right side of the last equation is freely reduced and hence of minimal length among all words equal to \( \omega_i \) in \( G_0 \). So the \( |\omega_i| \) are not bounded by an \( \mathcal{E}_{n+1} \)-function and no \( s_n \)-reduction function in \( \mathcal{E}_{n+1} \)-exists for \( G_n \). △

Our next lemma will be concerned with reduction functions for the groups \( H_n \).

**3.5. Lemma:** There is a \( s_n \)-reduction function \( \rho_n \in \mathcal{E}_4 \) for \( H_n = \langle H_{n-1}, s_n; s_n b s_n = s_{n-1} \rangle \). For \( n \geq 2 \) there is no \( s_n \)-reduction function for \( H_n \) in \( \mathcal{E}_3 \).

**Proof:** We define the functions \( \rho_n \) by induction on \( n \) and we use again some auxiliary functions \( h_n \) as in the proof of 3.4. They are defined in a different way in order to ensure some special properties needed later on. (It costs some effort to show \( \rho_n \in \mathcal{E}_4 \).)

R.A.I.R.O. Informatique théorique/Theoretical Informatics
Let again \( p_0 \) be the free reduction on \( H_0 = \langle b, \emptyset \rangle \). The functions \( h_n \) are defined as follows under the assumption that \( p_{n-1} \in E_4 \) has been found:

\[
h_n(e) = e,
\]

\[
h_n(x^i) = h_n(x^i), \quad x \in \{ b, s_1, \ldots, s_{n-1} \}, \quad i = \pm 1.
\]

\[
h_n(\omega x^i) = h_n(\omega) x^i, \quad \omega \in \{ b, s_1, \ldots, s_{n-1} \}.
\]

Here we assume \( v \) to be \( s_n \)-free.

If \( \omega \in H_n \) is given, we define \( \rho_n(\omega) \) as follows. If:

\[
\omega = \omega_0 s_n^i \omega_1 \ldots s_n^j \omega_p \quad (\omega_i \cdot s_n \text{-free}),
\]

then:

\[
\omega' = \rho_{n-1}(\omega_0) s_n^i \rho_{n-1}(\omega_1) \ldots s_n^j \rho_{n-1}(\omega_p) \quad \text{and} \quad \rho_n(\omega) = \hat{h}_n(\omega'),
\]

where \( \hat{h}_n(\omega') \) comes from \( h_n(\omega') \) by replacing the last \( s_n \)-free syllable \( u \) in \( h_n(\omega') \) by \( \rho_{n-1}(u) \).

The following three facts are easily proved:

(i) \( \rho_n(\omega) \) is full reduced and, if \( \omega \) is full reduced, \( \rho_n(\omega) = \omega \).

(ii) The order of pinch resolutions in the computation of \( \hat{h}_n(\omega') \) is left most — inner most. In particular if \( \omega' = \omega_1 s_n^t \omega_2 s_n^e \omega_3 \), where \( s_n^t \omega_2 s_n^e \) is the last pinch resolved, then \( \hat{h}_n(\omega') = \hat{h}_n(\omega_1) s_n^t \hat{h}_n(\omega_2) s_n^e \omega_3 \).

(iii) If \( \rho_n(\omega) = u_0 s_n^i u_1 \ldots s_n^j u_p \), then there is a decomposition:

\[
\omega = \omega_0 s_n^i \omega_1 \ldots s_n^j \omega_p \quad \text{with} \quad u_i \equiv \rho_p(\omega_i).
\]

(For the last two properties we need the special definition of \( h_n \).)

To prove \( \rho_n \in E_4 \) we need another fact: If \( u, v \) are fully reduced and \( i \in \mathbb{Z} \) then we have:

\[
|\rho_n(u b^i v)| \leq |i| |v| \quad \text{and} \quad |\rho_n(u s_n^i v)| \leq |i| |v|,
\]

where \( i \) is max \{ 1, |i| \}.
For the function $f_n$ we have $|f_n(\omega')| \leq f(|\omega'|)$ with $\omega'$ as above and $f$ as in definition 3.2. This is proved by induction on the number of $s_n$-pinches in the computation of $f_n(\omega')$ using (ii) and ($\star$).

A further induction on $n$ gives then the final result:

$$|\omega'| \leq f^{n-1}(|\omega'|) \quad \text{and} \quad |\rho_n(\omega)| \leq f^n(|\omega'|).$$

This means the reduction functions $\rho_n$ is bounded by an $\mathcal{O}_4$-function and hence is itself an $\mathcal{O}_4$-function.

To prove ($\star$) we use an induction on $n$ to prove the following fact:

If $u, v \in H_n$ are fully reduced and $i, j, k, l \in \mathbb{Z}$ then:

\begin{align*}
(a) \quad & ub^i s_n^i = b^j \text{ in } H_n \Rightarrow |j| \leq f^{|w|}, \\
& ub^i s_n^i = s_n^{i-1} \text{ in } H_n \Rightarrow |j| \leq f^{|w|}, \\
& |\rho_n(ub^i s_n^i v)| \leq ik2^{|w|}, \\
& |\rho_n(u s_n^k b^j v)| \leq ik2^{|w|}.
\end{align*}

We will show only the induction step from $n - 1$ to $n$, for the induction basis for $n = 1$ is proved in a similar way.

For (a) we make a further induction on $p = |i| = |u|_{s_n}$.

Let $p = 0$: $ub^i = b^j$ in $H_n$ implies $u \equiv b^k$, since $u$ is fully reduced, and we get $|j| \leq |k| + |l| \leq f^{|w|}$.

If $ub^i = s_n^{i-1}$ then $|j| = |u|_{s_{n-1}} \leq |u| \leq 2^{|w|}$.

Induction step $p - 1 \rightarrow p$: Let $u = u_0 s_n^i u_1$ where $u_0$ is $s_n$-free and $\varepsilon = -\text{sgn}(i)$.

We may assume $\varepsilon = -1$, the case $\varepsilon = 1$ is analogous.

Both, $ub^i s_n^i = b^j$ and $ub^i s_n^i = s_n^{i-1}$ in $H_n$ imply $ub^i s_n^i \in H_{n-1}$ and

\begin{equation*}
ub^i s_n^i = u_0 s_n^i u_1 b^j s_n^{i-1} s_n = u_0 s_n^i b^k s_n = u_0 s_n^{i-1} \text{ in } H_n,
\end{equation*}

where $u_1 b^i s_n^{i-1} = b^k$ in $H_n$ and so $|k| \leq f^{|w|}$.

For $ub^i s_n^i = b^j$ in $H_n$ we get $b^i = u_0 s_n^{i-1}$ in $H_{n-1}$ which leads to:

$$|j| \leq 2^{|u_0|} \leq 2^{|w|}.$$

For $ub^i s_n^i = s_n^{i-1}$ in $H_n$ we get $s_n^{i-1} = u_0 s_n^{k-1}$ in $H_{n-1}$ which leads to:

$$|j| \leq |u_0|_{s_{n-1}} + |k| \leq |u_0| + f^{|w|} \leq f^{|w|}.$$

So (a) is proved.

To prove (b) we first assume $k = 0$. Then we may assume $\rho_n(ub^i v)$ to be $s_n$-free.

For otherwise $u \equiv u_0 u_1$ and $v = v_1 v_0$ where $u_0$ and $v_0^{-1}$ are empty or end with $s_n^k$ and $\rho_n(ub^i v) \equiv u_0 \rho_n(u_1 b^j v_1) v_0$ with $\rho_n(u_1 b^j v_1)$ $s_n$-free. Now, of course,

$$|\rho_n(u_1 b^j v_1)| \leq f^{|u_1 b^j|} \text{ implies } |\rho_n(ub^i v)| \leq f^{|w|}.$$
Since $p_n(u^j b^j v)$ is $s_n$-free we must have $|u|_{s_n} = |v|_{s_n}$. We make now an induction on $p = |u|_{s_n}$. If $p = 0$ then $p_n(u^j b^j v) = p_{n-1}(u^j b^j v)$ and by induction hypothesis (for $n-1$) we get $| \rho_n(u^j b^j v) | \leq f \cdot 2 |u|_{s_n} |v|_{s_n}$. Let $u = u_0 s_n^{i-} u_1$ and $v = v_0 s_n^{i-} v_0$ where $u_0$ and $v_0$ are $s_n$-free. Since $u^j b^j v \in H_{n-1}$, $s_n^{i-} u_1 b^j v_1 s_n^{i-}$ must be a pinch, which means $u_1 b^j v_1 = b^j$ or $s_n^{i-} u_1 b^j v_1 s_n^{i-}$ depending on whether $\varepsilon = -1$ or $\varepsilon = 1$ and in both cases we have, by the induction hypothesis (for $p - 1$), $|j| \leq |p_n(u^j b^j v_1)| \leq f \cdot 2 |u|_{s_n} |v|_{s_n}$. We get:

$$\rho_n(u^j b^j v) = \begin{cases} 
\rho_{n-1}(u_0^j b^j v_0), & \varepsilon = -1, \\
\rho_{n-1}(u_0 s_n^{i-} v_0), & \varepsilon = 1.
\end{cases}$$

The induction hypothesis (for $n-1$) gives $| \rho_n(u^j b^j v) | \leq f \cdot 2 |u|_{s_n} |v|_{s_n}$. Let now $k \neq 0$. Because of the symmetry we only consider $\rho_n(u^j b^j v)$ and $k > 0$.

Let $k = j + m + l$ such that the first $j$ $s_n$ in $s_n^k$ react with $u$, the last $l$ $s_n$ in $s_n^k$ react with $b^j v$ and $m s_n$ remain unpinched. This means that we may decompose $u = u_1 u_0$, $v = v_0 v_1$ with $u_0 s_n^{i-} = s_n^{i-} u_1$ and $s_n^{i-} v_0 = b^j$ in $H_n$, where $u_0$ and $v_0$ are empty or begin with $s_n$ and $|j| \leq 2 |u|_{s_n} |v|_{s_n}$ by (a). If $m > 0$ then:

$$\rho_n(u^j b^j v) = \rho_{n-1}(u_1 s_n^{i-} v_1) s_n^m \rho_{n-1}(b^j v_1)$$

and:

$$| \rho_n(u^j b^j v) | \leq f \cdot 2 |u|_{s_n} |v|_{s_n} + |j| + |v_1| \leq 2 |u|_{s_n} |v|_{s_n} + l \cdot 2 |u|_{s_n} |v|_{s_n} + m \cdot 2 |u|_{s_n} |v|_{s_n} + |v_1| \leq k \cdot 2 |u|_{s_n} |v|_{s_n}.$$
Notice that for $H_2$ there is no $s_2$-reduction function in $\mathcal{E}_3$: Let $x_0 \equiv b$ and $x_{i+1} \equiv s_2 x_i^{-1} s_2 b s_2 x_i s_2$. Then $|x_i| \leq 2^{i+1}$ but $x_i \equiv b^{(i)}$ in $H_2$, so $|x_i|$ is $\mathcal{E}_3$-bounded and $b^{(i)}$ is not. Of course then there cannot exist a $s_n$-reduction function in $\mathcal{E}_3$ for $H_n (n \geq 2)$. △

Next we want to prove that there is an $a$-reduction function in $\mathcal{E}_4$ for $G_n = \langle H_n, a; \bar{a} b s_i, a = b s_i, i = 1, \ldots, n \rangle$. Since $G_n$ is a HNN-extension of $H_n$ with the identity as isomorphism we just have to show that the problem $\omega \in \langle b s_1, \ldots, b s_n \rangle$ in $H_n$ is $\mathcal{E}_4$-decidable. To do this we first need an auxiliary lemma.

3.6. Lemma: Let $U_n = \{ s_1 b, \ldots, s_n b \}, \omega \in H_n$ fully reduced and $l, m \in \mathbb{Z}$. If $\omega \notin \langle s_n \rangle$ in $H_n$ and $s_n^l \omega s_n^m \in \langle U_n \rangle$ in $H_n$ then $|l|, |m| \leq |\omega| + n$.

Proof: We will use without special mention the following properties of $f_n$ which are easily proved by induction: Let $\omega$ be fully reduced.

(a) If $\omega^{-1} a \omega = \overline{b^l} a \overline{b^l}$ in $G_n$ with $i \in \mathbb{Z}$, then $|i| \leq f_n(|\omega|)$.

(b) For $k \geq 0$, $i \in \mathbb{Z}$, $l \geq f_n(j)$ and $|\omega| \leq |j|$: If $\overline{b^l} a \overline{b^l} \omega^{-1} = s_n^k \overline{b^l} a \overline{b^l} s_n^k$ in $G_n$ where $s_n \overline{b^l} a \overline{b^l} s_n$ is $s_n$-reduced, then $i \geq f_n(|j - |\omega||) \geq 1$ and $k \leq |\omega|_{s_n}$.

To prove the lemma, let $s_n^l \omega s_n^m \in \langle U_n \rangle$ and $\omega \notin \langle s_n \rangle$. Then in $G_n$ we have $a s_n^l \omega s_n^m = \omega a s_n^m$ and so $s_n^l \omega s_n^m$. We consider three cases:

1. $l, m \geq 0$. This includes by taking inverses the case $l, m \leq 0$. Reduction of the $s_n a s_n$ blocks on both sides leads to:

$$\overline{b^{f_n(l-1)}} a \overline{b^{f_n(l-1)}} = \omega \overline{s_n^{m-(n-1)} b^{n-1} \overline{s_n^{m-(n-1)} \omega^{-1}}},$$

where:

$$s_n^{m-(n-1)} b^{n-1} \overline{s_n^{m-(n-1)}},$$

is $s_n$ reduced. Then $m-(n-1) \leq |\omega|_{s_n}$ or $m \leq |\omega|_{s_n} + (n-1)$ and:

$$\omega^{-1} \overline{b^{f_n(l-1)}} a \overline{b^{f_n(l-1)}} \omega = s_n^{m-(n-1)} b^{n-1} \overline{s_n^{m-(n-1)}} \omega^{-1}.$$
with \( p = l - (n-1) \) and \( q = m - (n-1) \). Here \( s_n b^{n-1} a b^{n-1} s_n \) is \( s_n \)-reduced. Suppose \( q \geq \omega \), so this is not possible. We get \( q \leq |\omega|, 1 \leq |\omega| + 1 \) and by symmetry \( p \leq |\omega| + 1 \) also. This implies \( l, m \leq |\omega| + n \).

3. \( l \geq 0 \) and \( m \leq 0 \), which may be written as \( s_i^l \omega s_m^m \in \langle U_n \rangle \) with \( l, m \geq 0 \). We now have \( s_i^l \omega s_m^m = s_i^l \omega s_m^m \omega^{-1} \) in \( G_n \) from which we get:

\[
\overline{b} f_i (l-1) a b f_i (m-1) \omega^{-1} = \omega \overline{b} f_i (l-1) a b f_i (m-1) \omega^{-1} \in G_n.
\]

We show that this equation can only hold if \( m, l \leq |\omega| \).

Let \( K_n^+ = \langle \{ k_{n, i} \mid i \geq 0 \} \rangle \) in \( G_n \) with \( k_{n, i} = b f_i (l) \). Notice that \( K_1^+ \supseteq K_2^+ \supseteq \ldots \supseteq K_n^+ \) because of \( f_n (m+1) = f_n (f_n (m)) \). By induction on \( n \) we prove that, if \( \omega \) is fully reduced and \( \omega \not\in \langle s_n \rangle \) with \( \omega k_{n, i} \omega^{-1} \in K_n^+ \), then \( i \leq |\omega| \). This is of course equivalent to our assertion above.

We only prove the induction step \( n-1 \rightarrow n \) because the case \( n = 1 \) is handled similarly. Suppose the claim is not true and let \( \omega \) be a counterexample of minimal length with \( \omega k_{n, i} \omega^{-1} \in K_n^+ \), \( \omega \not\in \langle s_n \rangle \) and \( 0 < |\omega| < i \).

\( \omega \) is not \( s_n \)-free: If \( e \neq \omega \) is \( s_n \)-free we have \( \omega k_{n, i} \omega^{-1} = \omega k_{n-1, i} \omega^{-1} \) with \( f_n (i-1) > i-1 \geq |\omega| \). So for \( \omega \not\in \langle s_{n-1} \rangle \) we can use the induction hypothesis and get that \( \omega k_{n, i} \omega^{-1} \notin K_{n-1}^+ \) which contradicts our assumption.

If \( \omega = s_i^l \) in \( G_{n-1} \) then \( 0 < |j| \leq |\omega| < i \) and by using 3.3 we get:

\[
\omega k_{n-1, f_i (i-1)} \omega^{-1} = k_{n-1, f_i (i-1)-j} \in G_n.
\]

But \( k_{n-1, f_i (i-1)-j} \notin K_n^+ \) because of:

\[
0 < |j| < i \quad \text{implies} \quad |j| \leq f_n (i-1) - f_n (i-2) < f_n (i) - f_n (i-1),
\]

and so:

\[
f_n (i-1) < f_n (i-1) - |j| < f_n (i) < f_n (i-1) + |j| < f_n (i+1),
\]

for \( 0 < |j| < i \). This again contradicts our assumption.

We claim that \( \omega = u_r s_n u_r s_{n-1} \ldots s_n u_0 \) with \( u_j s_n \)-free, \( r, |u_j| < |\omega| < i, u_0 \not\in e \) and \( u_r \not\in \langle s_{n-1} \rangle \).

Suppose \( \omega = \omega^i s_n u \), \( u s_n \)-free. Then \( u \not\in \langle s_{n-1} \rangle \) in \( G_{n-1} \), for, if \( u = s_i^k \), we have \( \omega = \omega^i b^k s_n \) in \( G_n \) and \( \omega^i b^k \) would be a shorter counterexample. Now \( s_n u k_{n, i} \omega^{-1} s_n \) must be a pinch which means (see 3.3) \( u k_{n, i} \omega^{-1} = s_i^p k_{n-1, i} s_i^p \)
for some \( p \geq 0, l > -(n-1) \) and the right hand side is \( s_{n-1} \)-reduced (equal exponents, because \( u \) is fully reduced and by symmetry). But we have
\[
|u| < l < f_n(i-1) \quad \text{and} \quad k_n, i \equiv k_{n-1, f_n(i-1)},
\]
so we will never reach from \( k_{n, i} \) some \( k_{n-1, j} \) with \( j \leq 0 \) by reducing \( u k_{n, i} u^{-1} \). We must have \( p = 0 \) and
\( u k_{n, i} u^{-1} \in K_{n-1}^+ \) which contradicts our induction hypothesis.

We have got \( \omega \equiv o \cdot s_n u \) and of course \( u \neq e \) (minimality of \( \omega \)). Now \( s_n u k_{n, i} u^{-1} s_n \) must be a pinch, which means \( u k_{n, i} u^{-1} = b^j a b^l \) and so:
\[
|u| < l < f_n(i-1) \quad \text{and} \quad s_n u k_{n, i} u^{-1} s_n = k_{n-1, i}.
\]

It is now easy to see that \( \omega \equiv u, s_n u, \ldots, s_n u, u_j, s_n \)-free and:
\[
s_n u_{j-1} \ldots s_n u_0 k_{n, i} u_0^{-1} s_n \ldots u_{j-1} s_n = k_{n-1, i},
\]
with \( l_j > f_n(i-1) \) for \( j = 1, \ldots, r \). The minimality of \( \omega \) implies that \( u_r \notin \langle s_{n-1} \rangle \), so by the induction hypothesis \( \omega k_{n, i} \omega^{-1} = u_r k_{n-1, i} u_r^{-1} \in K_{n-1}^+ \), which finishes our proof. \( \triangle \)

3.7. LEMMA: There is an \( a \)-reduction function in \( \mathcal{S}_4 \) for \( G_n = \langle H_n, a \rangle \).

Proof: It suffices to show that \( \langle U_n \rangle = \langle s_1, s_2, \ldots, s_n \rangle \) is a \( \mathcal{S}_4 \)-decidable subgroup of \( H_n \). We prove this by induction on \( n \).

Let \( \omega = \omega_0 s_{i_0}^{j_0} \omega_1 \ldots s_{i_p}^{j_p} \omega_p \) be fully reduced. If \( \omega \in \langle U_n \rangle \) then there is a word \( u \in U^* \), free reduced in the \( s_i \) and hence fully reduced (see the proof of lemma 3.1, with \( \omega = u \) in \( G_n \)). This means \( u = u_0(s_n b)^{j_0} \ldots (s_n b)^{j_p} u_p \) with \( u_i \in U^* \). Since \( u^{-1} \omega e \) in \( H_n \), there is a sequence \( j_{-1}, j_0, \ldots, j_{p-1}, j_p \) with \( j_{-1} = j_p = 0 \) and a system of \( p + 1 \) equations of the form:
\[
s_n u_{i-1}^{-1} b s_{n-1}^{j_{i-1}} \omega_i s_n = s_{n-1}^{j_i}, \quad \text{i.e.} \quad u_{i-1}^{-1} b s_{n-1}^{j_{i-1}} \omega_i = b^{j_i},
\]
or:
\[
s_n u_{i-1}^{-1} b^{j_{i-1}} \omega_i s_n = s_{n-1}^{j_i}, \quad \text{i.e.} \quad u_{i-1}^{-1} b^{j_{i-1}} \omega_i = b^{j_i},
\]
or:
\[
s_n b u_{i-1}^{-1} b s_{n-1}^{j_{i-1}} \omega_i s_n = b^{j_i}, \quad \text{i.e.} \quad b u_{i-1}^{-1} s_{n-1}^{j_{i-1}} \omega_i s_n = b^{j_i},
\]
or:
\[
s_n b u_{i-1}^{-1} b^{j_{i-1}} \omega_i s_n = b^{j_i}, \quad \text{i.e.} \quad b u_{i-1}^{-1} b^{j_{i-1}} \omega_i s_n = b^{j_i}. \]

We claim \( |j_i| \leq |\omega| + n \cdot |\omega| \). Then according to the induction hypothesis one can test by a \( \mathcal{S}_4 \)-process, whether the system of equations is solvable, i.e. whether \( u \in \langle U_n \rangle \) with \( \omega = u \) in \( H_n \) exists. So \( \langle U_n \rangle \) is a \( \mathcal{S}_4 \)-decidable subgroup of \( H_n \).
The proof of $|j| \leq |\omega| + n \cdot |\omega|_{\epsilon_i}$, $i=1, \ldots, p-1$ is by induction on $p$. If $\epsilon_1 = -1$ then $u_0 \omega_0 = s_{n-1}^b$ in $H_{n-1}$, hence $|j_0| \leq |\omega_0| + (n-1)$ by lemma 3.6. (We have $s_{n-1}^b \omega_{n-1}^{-1} \in \langle U_{n-1} \rangle$, and if $\omega_0 \in \langle s_{n-1} \rangle$ then $|j_0| \leq |\omega_0|$).

So:

$$\omega = u_0^{-1} s_{n-1}^b \bar{s}_n \omega' = u_0 \bar{s}_n b^\omega \omega', \quad \text{where } \omega' \equiv \omega_1 s_1^\epsilon \omega_2 \ldots s_n^\epsilon \omega_p.$$ 

Now we can argue with $b^\omega \omega'$ instead of $\omega$ (there may be some cancellation of $b^\epsilon$'s). By induction hypothesis:

$$|j_i| \leq |\omega'| + j_0 + (n-1)|\omega'|_{\epsilon_i} \leq |\omega| + n |\omega|_{\epsilon_i}.$$ 

If $\epsilon_p = +1$ the same argument works with $\omega^{-1}$ instead of $\omega$.

Let $\epsilon_1 = \epsilon_2 = \ldots = \epsilon_q = 1$, $\epsilon_{q+1} = -1$, $q < p$, and $\hat{\omega} = \omega_0 s_n \omega_1 \ldots s_n \omega_q$. The first $q+1$ equations are:

$$u_0^{-1} \omega_0 = b^h,$$
$$u_i b^h s_{n-1}^h \omega_i = b^h, \quad i = 1, \ldots, q-1,$$
$$\bar{b} u_q b^h s_{n-1}^h \omega_q = s_{n-1}^h.$$

This implies:

$$|j_{i-1}| \leq |\omega_i| + |j_i| + 1 + (n-1) \quad \text{for } i = 1, \ldots, q-1$$

and $|j_{q-1}|, |j_q| \leq |\omega_q| + 1 + (n-1) = |\omega_q| + n$ by lemma 3.6.

This gives:

$$|j_i| \leq |\omega| + n \cdot q \leq |\omega| + n |\omega|_{\epsilon_i} \quad \text{for } i = 0, 1, \ldots, q.$$ 

Again we get $|j_i| \leq |\omega| + n |\omega|_{\epsilon_i}$ for all $i$ as in the case $\epsilon_1 = -1$. $\Delta$
