ANALYTIC APPROXIMATION FOR HOMOGENEOUS

SOLUTIONS OF LINEAR PDE's.

by M.S. BAOUENDI

Let $P(x,D)$ be a differential operator with analytic coefficients in an open set of $\mathbb{R}^n$. Assume that the principal symbol of P is nowhere identically zero. It is natural to ask the following question :

Is it true that any distribution solution of $P(x,D)u = 0$ is locally a limit of real analytic solutions of the same equation?

The answer to this question is not known. However an affirmative answer is given in Baouendi-Trèves [3] (see also [2] for first order overdetermined systems) when P has simple (complex) characteristics. An affirmative answer is also given in Baouendi-Rothschild [1] when P is a left invariant operator defined on a general Lie group. Detailed proofs could be found in [1] and [3].

First we state the result obtained in [3]. Denote by t the variable in $\mathbb{R}$, by x the one in $\mathbb{R}^n$. Let Ω be an open set in $\mathbb{R} \times \mathbb{R}^n$ containing the origin. We consider a first order linear differential operator of the form

$$L = I_N \frac{\partial}{\partial t} - \sum_{j=1}^n A_j(t,x) D_{x_j} - A_0(t,x),$$

where A_j are real-analytic in Ω valued in the space of complex $N \times N$ matrices, and I_N is the identity matrix. Set

$$a(t,x,\xi) = \sum_{j=1}^n A_j(t,x) \xi_j.$$

We assume that for every $(t,x,\xi) \in \Omega \times (\mathbb{R}^n \setminus \{0\})$ the matrix $a(t,x,\xi)$ has N distinct eigenvalues $\lambda_j(t,x,\xi)$, $j = 1, \dots, N$.

Theorem 1 :

Let $h \in \mathcal{D}'(\Omega')$, $0 \in \Omega' \subset \Omega$, satisfying $Lh = 0$. There exist an

open neighborhood of 0, $\Omega'' \subset \Omega'$, and a sequence of analytic functions h_ν in Ω'' satisfying :

- (i) $L h_\nu = 0$ in Ω''
- (ii) $\lim h_\nu = h$ in $\mathcal{D}'(\Omega'')$.

Furthermore if h is of class C^k , then the convergence in (ii) is in $C^k(\Omega'')$.

Now we state the result in [1].

Theorem 2 :

Let P be a left invariant differential operator defined on a Lie group G . For every open set $U \subset G$, neighborhood of the identity $e \in G$, there exists another open neighborhood of e , $W \subset G$, such that if u is a distribution on G satisfying $Lu = 0$ in U , then there exists a sequence u_ν of real analytic functions defined in W and satisfying

- (i) $L u_\nu = 0$ in W ,
- (ii) $\lim u_\nu = u$ in $\mathcal{D}'(W)$.

Furthermore if u is of class C^k , then the convergence in (ii) is in $C^k(W)$.

We sketch now the proof of theorem 1 in the case of a single complex vector field, i.e. $N = 1$. Set

$$L = \frac{\partial}{\partial t} - \sum_{j=1}^n a_j(t, x) \frac{\partial}{\partial x_j},$$

where a_j are analytic functions in $\Omega = I \times U$, $0 \in I \subset \mathbb{R}$, $0 \in U \subset \mathbb{R}^n$. Let $h \in C^1(\Omega)$, $L h = 0$, and $g \in C_0^\infty(U)$, $g \equiv 1$ near the origin in $\mathbb{R}^n$. Set

$$u(t, x) = g(x) h(t, x), \quad L u = f.$$

Note that f vanishes in a neighborhood of $x = 0$ for all $t \in I$.

For $j = 1, \dots, n$, denote by $Z_j(t, x)$ the solution of the Cauchy problem

$$L Z_j = 0 \quad Z_j \Big|_{t=0} = x_j ,$$

and set $Z = (Z_1, \dots, Z_n)$.

For $v \in \mathbb{Z}_+$ define the operator K_v by

$$(1) \quad (K_v u)(t, x) = \left(\frac{v}{\sqrt{\pi}}\right)^n \int_{\mathbb{R}^n} e^{-v^2 [Z(t, x) - Z(t, y)]^2} \det(Z'_y(t, y)) u(t, y) dy.$$

The operator K_v has the following properties :

- (a) $K_v(L u) = L(K_v u)$
- (b) $\lim_{v \rightarrow \infty} K_v u = u$ uniformly in a fixed neighborhood of the origin in $\mathbb{R}^{n+1}$
- (c) $K_v f$ extends holomorphically in x to a fixed neighborhood of the origin in $\mathbb{C}^n$, and there converges to 0.

Assuming (a) (b) and (c), set

$$h_v = K_v u - v_v$$

where v_v is the solution of

$$L v_v = K_v f \quad v_v \Big|_{t=0} = 0.$$

It follows from (c) that $\lim_{v \rightarrow \infty} v_v = 0$. Therefore (a) and (b) imply that we have (i) and (ii) of the conclusion of theorem 1.

Q.E.D.

Note that the operator K_v defined by (1) can be written

$$(2) \quad (K_v u)(t, x) = \frac{1}{(2\pi)^n} \iint e^{i[Z(t, x)\xi - Z(t, y)\xi] - \varepsilon |\xi|^2} \det(Z'_y(t, y)) u(t, y) dy d\xi.$$

We limit ourselves to mention that the proof of theorem 1 in

the general case (i.e. $N > 1$) is done by reducing the system L to a diagonal one, at least microlocally. Operators similar to (2) are introduced, where $Z(t,x)\xi$ is replaced by $\Psi(t,x,\xi)$ satisfying

$$\partial_t \Psi - \lambda(t,x,\partial_x \Psi) = 0 ,$$

$$\Psi|_{t=0} = x \cdot \xi ,$$

λ stands for one of the eigenvalues of the matrix a . The exponential function in (2) is multiplied by analytic amplitudes determined by geometrical optics.

The proof of theorem 2 is based on the use of convolution with a suitable Gaussian defined near $e \in G$, and the use of the Campbell-Hansdorff formula in order to prove a result similar to (c) above.
