ON THE DISCRETE MAXIMUM PRINCIPLE
FOR PARABOLIC DIFFERENCE OPERATORS (*)

by HUNG-JU KUO (1, 2) and N. S. TRUDINGER (3)

Communicated by R. TEMAM

Abstract. — We derive a discrete analogue for parabolic difference inequalities of the Krylov maximum principle for parabolic differential inequalities. The result embraces both explicit and implicit difference schemes and extends to the parabolic case our previous work on linear elliptic difference inequalities with random coefficients.

Résumé. — Pour des inégalités aux différences paraboliques, on établit l'analogue discret du principe du maximum de Krylov connu pour les inégalités paraboliques. Le résultat obtenu concerne à la fois des schémas aux différences explicites et implicites et est une généralisation au cas parabolique de notre travail antérieur concernant les inégalités aux différences elliptiques linéaires à coefficients aléatoires.

1. INTRODUCTION

In this paper we establish discrete versions of the Krylov maximum principle [4, 5] for linear parabolic partial differential operators of the form

\[ \mathcal{L} u = a^{ij} D_{ij} u + b^i D_i u + cu - D_t u \] (1.1)

in cylindrical regions \( Q^+ = \Omega \times \mathbb{R}^+ \subset \mathbb{R}^{n+1} \), where \( \Omega \) is a domain in Euclidean \( n \)-space, \( \mathbb{R}^n \). Our results are analogues of the discrete version of the Aleksandrov maximum principle for elliptic operators,

\[ Lu = a^{ij} D_{ij} u + b^i D_i u + cu \] (1.2)

established in our previous work [6] (Theorem 2.1). As in [6], our estimates are formulated in such a way that their continuous versions follow via Taylor's formula.

Our discretizations of the operator (1.1) will involve linear difference operators, essentially of positive type, acting on space-time mesh functions. We will consider meshes in $\mathbb{R}^{n+1}$ of the form,

$$E = E_{h, \tau} = \mathbb{Z}^n_h \times \mathbb{Z}_\tau$$

$$= \{(x, t) \in \mathbb{R}^{n+1} | x = (m_1, ..., m_n) h, t = m \tau, m_i, m \in \mathbb{Z}\} \quad (1.3)$$

with spatial mesh length $h > 0$ and time step $\tau > 0$. A real-valued function on $E$ is called a mesh function and, for fixed $y \neq 0, \in \mathbb{Z}_n^y$, we define the following basic difference operators, acting on the linear space of mesh functions, $\mathcal{M}(E)$:

$$\delta_y^+ u(x, t) = \frac{1}{|y|} \{u(x+y, t) - u(x, t)\} ,$$

$$\delta_y^- u(x, t) = \frac{1}{|y|} \{u(x, t) - u(x-y, t)\} ,$$

$$\delta_y u(x, t) = \frac{1}{2} (\delta_y^+ + \delta_y^-) u(x, t) = \frac{1}{2|y|} \{u(x+y, t) - u(x-y, t)\} ,$$

$$\delta_y^2 u(x, t) = \delta_y^+ \delta_y^- u(x, t)$$

$$= \frac{1}{|y|^2} \{u(x+y, t) - 2u(x, t) + u(x-y, t)\} ,$$

$$\delta_{\tau}^- u(x, t) = \frac{1}{\tau} \{u(x, t) - u(x, t - \tau)\} .$$

The spatial part of our difference operators will be determined by second order difference operators of the form

$$L_h u(x, t) = \sum_y a(x, t, y) \delta_y^2 u(x, t) +$$

$$+ \sum_y b(x, t, y) \delta_y u(x, t) + c(x, t) u(x, t) \quad (1.5)$$

with real coefficients $a, b, c$, having compact support with respect to $y$, and satisfying as in [6], the condition

$$a(x, t, y) - \frac{1}{2} |y| |b(x, t, y)| \geq 0 . \quad (1.6)$$

Such operators can be used to approximate uniformly elliptic differential
operators of the form (1.2) ([6, 8]). From the operators (1.5) we construct parabolic difference operators of the form

$$\mathcal{L}^{(a)} u(x, t) = \mathcal{L}_{h, \tau}^{(a)} u(x, t) = (1 - \alpha) L_h u(x, t) + \alpha L_h u(x, t - \tau) - \delta \tau^- u(x, t)$$  \hspace{1cm} (1.7)

where \(\alpha\) is a fixed number satisfying \(0 \leq \alpha \leq 1\). When \(\alpha = 0\), the operator \(\mathcal{L}\) is called implicit, when \(\alpha = 1\), the operator \(\mathcal{L}\) is called explicit and the general case is referred to as explicit-implicit in correspondence with the resultant difference schemes. The operators (1.7) are of positive type (as defined by Motzkin and Wasow [8], see also [7]), if, as well as (1.6) holding, we have

$$\alpha \left( 2 \sum_{y} \frac{a(x, t, y)}{|y|^2} - c(x, t) \right) \leq 1 , \hspace{1cm} (1.8)$$

$$\left( 1 - \alpha \right) c(x, t) + \alpha C(x, t - \tau) \leq 0 . \hspace{1cm} (1.9)$$

In the parabolic case, (1.9) can be achieved by replacement of \(u\) by \(e^{Ct} u\) for an appropriate constant \(C\), provided \(\tau\) is sufficiently small. Consequently only (1.6) and (1.8) will be essential for us with (1.9) being replaced by a weaker condition (see (2.6)).

We shall formulate a discrete version of the Krylov maximum principle in the next section for operators \(\mathcal{L}_{h, \tau}^{(a)}\) satisfying stricter conditions than (1.6) and (1.8) corresponding to the non-degeneracy condition assumed in [6]. In Section 3 we provide some basic inequalities from Krylov’s paper [4] which are used in our proof which is supplied in Section 4. Finally in Section 5 we relate the discrete and continuous versions of the maximum principle. In an ensuing paper, we shall apply Theorem 2.1 to the derivation of local estimates, corresponding to those in the elliptic case [6].

2. THE DISCRETE MAXIMUM PRINCIPLE

In this section we formulate a discrete maximum principle for the operator \(\mathcal{L}_{h, \tau}^{(a)}\), Theorem 2.1. The spatial operators \(L_h\) in (1.5) will be subjected to the same non-degeneracy condition as in [6]. That is, as well as (1.6), we assume for each point \(x \in \Omega_h\) and \(t = m\tau\), \(m = 0, 1, ..., N\) for some \(N \in \mathbb{N}\), there exists an orthogonal set of vectors \(y^1, ..., y^n \in \mathbb{Z}_h^n\) such that

$$\left( 1 - \alpha \right) \left\{ a(x, t, y^i) - \frac{|y^i|^2}{2} |b(x, t, y^i)| \right\} +$$

$$+ \alpha \left\{ a(x, t - \tau, y^i) - \frac{|y^i|^2}{2} |b(x, t - \tau, y^i)| \right\} \geq \lambda_i(x, t) > 0 , \hspace{1cm} (2.1)$$

vol. 27, n° 6, 1993
Furthermore we will assume the coefficients $a$ vanish whenever
$$\|y\| = \|y\|_2 > Kh$$
for some fixed $K \in \mathbb{N}$ and write
$$\mathcal{D} = \mathcal{D}(x, t) = \prod_{i=1}^{n} \lambda_i(x, t) \quad (2.2)$$
$$a(x, t) = \sum_y a(x, t, y), \quad b(x, t) = \sum_y |b(x, t, y)|,$$
$$a_0 = \max a(x, t), \quad b_0 = \max b(x, t), \quad c^+ = \max c^+ (x, t).$$
We also need to assume non-degeneracy with respect to the time variable and this we do by strengthening the condition (1.8) to
$$\alpha \tau \left( 2 \sum_y \frac{a(x, t, y)}{\|y\|^2} - c(x, t) \right) \leq 1 - \gamma (x, t) \quad (2.3)$$
for some positive function $\gamma$. Note that (2.3) will be satisfied if the time step $\tau$ and the ratio $\tau / h^2$ are sufficiently small, in particular if
$$2 \alpha a_0 K \tau / h^2 + \alpha \tau c_0^+ < 1 \quad (2.4)$$
When the operator $\mathcal{D}$ is implicit, $\alpha = 0$ and (2.3), (2.4) are automatically satisfied. Combining (2.2) with (2.3), we also write
$$\mathcal{D}(x, t) = \gamma (x, t - \tau) \mathcal{D}(x, t), \quad \mathcal{D}^* = (\mathcal{D})^{n+1}. \quad (2.5)$$
In accordance with our remarks after condition (1.9), we shall replace (1.9) by the condition
$$(1 - \alpha) \tau c \leq 1 - \mu \quad (2.6)$$
where $\mu$ is a positive constant. Writing $T = \tau N$, we distinguish interior and boundary points in the discrete cylinder
$$Q_{h, \tau} = \Omega_h \times (\mathbb{Z} \cap [0, T]),$$
corresponding to the operators $\mathcal{D}^{(\alpha)}$. First we define the discrete interiors and boundaries of the set $\Omega_h$ corresponding to the operators $\mathcal{D}^{(\alpha)}$ by
$$\Omega^0_h(t) = \{x \in \Omega_h | (1 - \alpha) a(x, t, y) + \alpha a(x, t - \tau, y) = 0, \forall x + y \notin \Omega_h\}$$
$$\Omega^b_h(t) = \Omega_h - \Omega^0_h(t).$$
The discrete parabolic interior and boundary of the cylinder $Q_{h, \tau}$ are then defined by

$$Q^0_{h, \tau} = \bigcup_{m=1}^N \Omega^0_h(m\tau) \times \{m\tau\}$$

$$= \{(x, t) \in Q_{h, \tau} | (1 - \alpha) a(x, t, y) + \alpha a(x, t - \tau, y) = 0, \forall (x + y, t) \notin Q_{h, \tau}, t > 0\}$$

$$Q^b_{h, \tau} = Q_{h, \tau} - Q^0_{h, \tau}$$

$$= \bigcup_{m=1}^N [\Omega^b_h(m\tau) \times \{m\tau\}] \cup [\Omega_h \times \{0\}].$$

We also need to recall the notion of upper contact set, as used in [6]. Namely, if $u$ is a spatial mesh function defined on $\Omega_h$, we define the upper contact set of $u$, $\Gamma^+ = \Gamma^+(u)$ to be the subset where $u$ is concave, that is $\Gamma^+$ consists of those points $x$ in $\Omega_h$ for which there exists a hyperplane $P = P(x)$ in $\mathbb{R}^{n+1}$ passing through $(x, u(x))$ and lying above the graph of $u$. For a space-time mesh function $u$ defined on the cylinder $Q_{h, \tau}$ we then define its spatial upper contact set by

$$\Gamma^+ = \Gamma^+(u) = \{(x, t) \in Q_{h, \tau} | x \in \Gamma^+_i \}$$

where $\Gamma^+_i$ denotes the upper contact set on $\Omega_h$ of the spatial mesh function, $u'(x) = u(x, t)$. We also define the increasing set of a space-time mesh function $u$ by

$$I = I(u) = \{(x, t) \in Q_{h, \tau} | u(x, t) > u(x, s), \text{for all } s, 0 \leq s < t\}$$

and let

$$\mathcal{S} = \mathcal{S}(u) = \Gamma^+ \cap I$$

denote the increasing-upper contact set of $u$. We can now state the following discrete analogues of the Krylov maximum principle corresponding to the operator $\mathcal{L}^{(\alpha)}$, $0 \leq \alpha \leq 1$.

**Theorem 2.1:** Let $u$ be a space-time mesh function on the cylinder $Q_{h, \tau}$ satisfying the difference inequality,

$$\mathcal{L}^{(\alpha)} u \geq f \text{ in } Q^0_{h, \tau}, \quad (2.7)$$

**together with the boundary condition,**

$$u \leq 0 \text{ in } Q^b_{h, \tau}, \quad (2.8)$$

vol. 27, n° 6, 1993
Then we have the estimate
\[
\max_{Q_{h,r}} u \leq C R^{\frac{n+1}{n}} \left\| f/\mathcal{D}^* \right\|_{L^{n+1}(\mathcal{S})},
\]  
(2.9)

where \( C \) is a constant depending only on \( n, K, \mu, \frac{b_0 T}{R}, c_0^+ T, R = \text{diam } \Omega \) and \( \mathcal{S} \) is the increasing-upper contact set of \( u \).

We remark that, as with the continuous case [4, 5], the estimate (2.8) is one of several variants which stem from the special case \( b_0 = c_0^+ = 0 \). A more explicit form of the constant \( C \), with an exponential dependence on the quantities \( b_0 \) and \( c_0^+ \) will be given in the course of the proof of Theorem 2.1. With the integral norm in (2.9) taken over \( \mathcal{S} \), rather than \( Q_{h,r} \), the estimate (2.9) actually corresponds to refinements of the original Krylov estimate due to Nazarov and Ural'tseva [9], Reye [10] and Tso [11]. The form of estimate (2.9), involving the integral \( L^n + 1 \) norm, rather than a \( \text{sup} \) norm, will be crucial in deriving local estimates and subsequent stability results in our ensuing paper (cf. [6, 7]).

3. PRELIMINARIES

Our proof of the maximum principle, Theorem 2.1 is based on certain inequalities of Krylov [4], together with the discrete adaptation in [6] of the geometric argument of Aleksandrov. As in [6], the notion of normal mapping (or supergradient) is crucial, the normal mapping of a spatial mesh function \( u \) on the set \( \Omega_h \) being defined by
\[
\chi(x) = \chi_u(x) = \{ p \in \mathbb{R}^n | u(z) \leq u(x) + p \cdot (z-x), \forall z \in \Omega_h \}. \tag{3.1}
\]
The upper contact set \( \Gamma^+ \) of \( u \) is thus the subset of \( \Omega_h \) where \( \chi_u \) is non-empty. Note that in the discrete case, \( \chi(\Omega_h) = \mathbb{R}^n \) and that \( \chi(x) \) is unbounded whenever \( x \) is an extreme point of the convex hull of \( \Omega_h \), which we denote as \( \hat{\Omega}_h \). The basic inequalities we need are encompassed in the following lemmas, which correspond to special cases of [4], Corollary 1.

**Lemma 3.1:** Let \( u \) and \( v \) be mesh functions on \( \Omega_h \), vanishing at extreme points of \( \hat{\Omega}_h \) and satisfying \( u \geq v \) on \( \Omega_h \). Then we have the inequalities,
\[
0 \leq \sum_{x \in \hat{\Omega}_h} (u(x)|\chi_u(x)| - v(x)|\chi_v(x)|) \leq (n+1) \sum_{x \in \hat{\Omega}_h} (u-v)(x)|\chi_u(x)| \tag{3.2}
\]
Note that in (3.2), we use $|S|$ to denote the $n$ dimensional Lebesgue measure of a measurable set $S$ in $\mathbb{R}^n$ and the terms in the above sums are understood to vanish whenever $u$ and $v$ vanish, in particular at the extreme points of the convex set $\hat{\Omega}_h$. In fact there is no loss of generality in replacing the functions $u$ and $v$ in Lemma 3.1 by their concave envelopes which then vanish on $\partial \hat{\Omega}_h$. In this form, Lemma 3.1, is directly covered by Krylov [4].

**Lemma 3.2**: Let $u$ be a mesh function of $\Omega_h$, vanishing at extreme points of $\hat{\Omega}_h$. Then for any $z \in \Omega_h$, we have the estimate,

$$u(z) = \left\{ \frac{d^n_z}{\omega_n \sum_{x \in \partial_h} u(x)} \int_x \frac{1}{n+1} \right\},$$

(3.3)

where $d_z = \max_{x \in \partial_h} |z - x|$.

For completeness, we shall describe the proofs of Lemmas 3.1, 3.2 following Krylov [4]. First we need their analogues for smooth functions. Setting $Q_T = \Omega \times (0, T)$ and assuming $u \in C^\infty(\mathbb{R}^{n+1})$, with $u = 0$ on $\partial \Omega \times (0, T)$, we have, by integration by parts,

$$\int_{Q_T} D_t u (\det D^2 u) \, dx \, dt = - \int_{Q_T} uD_t (\det D^2 u) \, dx \, dt +$$

$$+ \int_{\partial T} \{ u(x, T) \det D^2 u(x, T) - u(x, 0) \det D^2 u(x, 0) \} \, dx .$$

Letting $[u^{ij}]$ denote the cofactor matrix of the Hessian matrix $D^2 u$, we then have

$$\int_{Q_T} uD_t (\det D^2 u) \, dx \, dt = \int_{Q_T} uu^{ij} D_{ijt} u \, dx \, dt$$

$$= \int_{Q_T} (D_{ij} u) u^{ij} D_t u \, dx \, dt$$

$$= n \int_{Q_T} (\det D^2 u) D_t u \, dx \, dt ,$$

by integration by parts, since $\sum_i u^{ij} = 0$, for each $j$. Accordingly, we obtain the identity,

$$(n + 1) \int_{Q_T} D_t u (\det D^2 u) \, dx \, dt =$$

$$= \int_n \{ u(x, T) \det D^2 u(x, T) - u(x, 0) \det D^2 u(x, T) \} \, dx .$$

(3.4)
Now let us assume that $\Omega$ is convex and that $u$ and $v$ are convex functions in $C^2(\overline{\Omega})$ vanishing on the boundary $\partial\Omega$, with $u \leq v$ in $\Omega$. Setting

$$w(x, t) = (1 - t) u(x) + t v(x),$$

we shall apply (3.4) to $w$ on $Q_1$. Since $D^2w \geq 0$ by convexity and $D_tw = v - u \geq 0$, we see immediately that

$$\int_{\Omega} u \det D^2 u \leq \int_{\Omega} v \det D^2 v. \quad (3.5)$$

Furthermore,

$$D_t \left\{ \int_{\Omega} w_t \det D^2 w \right\} = \int_{\Omega} (D_t w) w^{ij} D_{ijt} w$$

$$= - \int_{\Omega} w^{ij} (D_{it} w) D_{jt} w$$

$$\leq 0$$

since $[w^{ij}] \geq 0$, by virtue of the convexity of $w$. Hence

$$\int_{\Omega} w_t \det D^2 w \leq \int_{\Omega} (v - u) \det D^2 w(x, 0)$$

$$= \int_{\Omega} (v - u) \det D^2 u,$$

so that from (3.4) and (3.5) we conclude

$$0 \leq \int_{\Omega} (v \det D^2 v - u \det D^2 u) \leq (n + 1) \int_{\Omega} (v - u) \det D^2 u, \quad (3.6)$$

which is the smooth version of (3.2). The passage from (3.6) to (3.2) is achieved by approximation. If $u$ is a concave function on $\Omega$, we define a Borel measure $\omega_u$ by

$$\omega_u(E) = \left| \chi_u(E) \right| \quad (3.7)$$

for any Borel set $E \subset \Omega$. Clearly, $\omega_u$ is finite if $u \in C^{0,1}(\overline{\Omega})$ and furthermore, when $u \in C^2(\Omega)$, we have the representation

$$\omega_u(E) = \int_E \det (-D^2 u), \quad (3.8)$$

so that $\omega_u$ is absolutely continuous with respect to Lebesgue measure.
Switching from convex to concave functions, it follows that we can write (3.6) in the form

$$0 = \int_{\Omega} (u \, d\omega_u - v \, d\omega_v) \leq (n + 1) \int_{\Omega} (u - v) \, d\omega_u,$$

where $u, v \in C^{0,1}(\overline{\Omega}) \cap C^2(\Omega)$ are concave on $\Omega$, vanish on $\partial\Omega$ and satisfy $u \geq v$ in $\Omega$. Using the property that the sequence of measures $\{\omega_{u_m}\}$ converges weakly to $\omega_u$, when the sequence $\{u_m\}$ converges uniformly to $u$, we may then extend (3.9) to concave functions $u, v \in C^{0,1}(\overline{\Omega})$ and (3.2) thus follows as a special case; (see [2, 4] for further details). The estimate (3.3) follows from the first inequality in (3.9), as in [4], by taking $v$ to be the conical function

$$v(x) = u(z) \left(1 - \frac{|x - z|}{d_z}\right),$$

on the ball $\{|x - z| < d_z\}$.

4. PROOF OF THEOREM 2.1

First we consider the case when $b = c = 0$. It is convenient to consider the difference inequality (2.7) as a system of difference inequalities for the spatial mesh functions $u_m, m = 0, ..., N$ given by

$$u_m = u(x, m\tau). \quad (4.1)$$

Writing

$$a_m(x, y) = a(x, y, m\tau), \quad f_m(x) = f(x, m\tau),$$

$$\Omega^0_m = \Omega^0_h(m\tau), \quad \Omega^b_m = \Omega^b_h(m\tau),$$

we see that (2.7), (2.8) are thus equivalent to the system,

$$(1 - \alpha) \sum a_m(x, y) \delta^2_y u_m(x) + \alpha \sum a_{m-1}(x, y) \delta^2_y u_{m-1}(x) -$$

$$- \frac{1}{\tau} (u_m(x) - u_{m-1}(x)) = f_m(x), \quad \text{for} \quad x \in \Omega^0_m,$$

$$u_m \leq 0, \quad \text{in} \quad \Omega^b_m,$$

$$u_0 \leq 0, \quad m = 1, ..., N.$$
In order to use Lemma 3.1, we need to replace \( u_m \) by an increasing sequence \( v_m \) defined by
\[
v_m = \max_{j \leq m} u_j^+.
\]

We observe that \( v_m = 0 \) in \( \bigcap_{j=m}^N \Omega_j^b \), \( v_0 = 0 \), \( m = 1, \ldots, N \) and moreover, setting
\[
\alpha_m = (1 - \alpha) a_m + \alpha a_{m-1},
\]
it follows that whenever \( v_m(x) > v_{m-1}(x) \), then \( v_m(x) = u_m(x) \), and we have the difference inequality
\[
\sum \alpha_m(x, y) \delta_y^2 v_m(x) \geq (1 - \alpha) \sum \alpha_m(x, y) \delta_y^2 u_m(x) + \alpha \sum \alpha_{m-1}(x, y) \delta_y^2 u_{m-1}(x) - 2 \alpha \sum \frac{a_{m-1}(x, y)}{|y|^2} (u_m(x) - u_{m-1}(x))
\]
\[
\geq \left( \frac{1}{\tau} - 2 \alpha \sum \frac{a_{m-1}(x, y)}{|y|^2} \right) (u_m(x) - u_{m-1}(x)) + f_m(x)
\]
\[
\geq \frac{\gamma_{m-1}(x)}{\tau} (u_m(x) - u_{m-1}(x)) + f_m(x) \tag{4.3}
\]
by (4.2), (2.3) where \( \gamma_m(x) = \gamma(x, m \tau), \ m = 1, \ldots, N \). Letting \( \Gamma_m^+ = \Gamma^+(v_m) \) and
\[
\mathcal{S}_m = \{ x \in \Gamma_m^+ | v_m(x) > v_{m-1}(x) \}
\]
we can now follow our proof of Theorem 2.1 in [6], to obtain
\[
\delta_y^2 v_m \leq 0 \tag{4.4}
\]
for all \( x \in \Gamma_m^+ \), \( x + y \in \Omega_x \). Consequently, from (4.3), we have
\[
- \sum_{i=1}^n \alpha_m(x, y^i) \delta_y^2 v_m(x) + \frac{\gamma_{m-1}(x)}{\tau} (u_m(x) - u_{m-1}(x)) \leq - f_m(x) \tag{4.5}
\]
for \( x \in \mathcal{S}_m \), where \( y^i = y^i(x, m \tau) \), is as in (2.1). Letting \( \chi_m = \chi_{v_m} \), we can then estimate, as in [6], Theorem 2.1,
\[
|\chi_m(x)| \leq \prod_{i=1}^n \left\{ \frac{1}{|y^i|} \{ 2 v_m(x) - v(x + y^i) - v(x - y^i) \} \right\}
\]
\[
= \prod_{i=1}^n \left( - |y^i| \delta_y^2 v_m(x) \right), \tag{4.6}
\]
so that using the arithmetic geometric mean inequality, we obtain from (4.5),

\[
(v_m - v_{m-1})(x)|x_m(x)| \leq \frac{\tau}{\gamma_{m-1}} \left( \frac{|f_m(x)|}{n+1} \right)^{n+1} \prod_{i=1}^{n} \frac{|y^i|}{\alpha_m}
\]

\[
\leq (Kh)^n \tau \left( \frac{|f_m(x)|}{(n+1) \mathcal{D}^*_m} \right)^{n+1}.
\]

(4.7)

where

\[
\mathcal{D}^*_m = \left( \gamma_{m-1} \prod_{i=1}^{n} \lambda_{i,m} \right)^{\frac{1}{n+1}}
\]

\[
\lambda_{i,m}(x) = \lambda_i(x, m\tau), \quad m = 0, ..., N.
\]

Since the left hand side of (4.7) vanishes for \(x \notin \mathcal{S}_m\), the inequality clearly extends to all \(x \in \Omega_h\), with \(f_m(x)\) replaced by zero for \(x \notin \mathcal{S}_m\). We are now in a position to apply Lemma 3.1. Indeed this yields the estimate

\[
\sum_{x \in \Omega_h} v_m(x)|x_m(x)| - v_{m-1}(x)|x_{m-1}(x)| \leq
\]

\[
(n + 1) \sum_{x \in \Omega_h} (v_m - v_{m-1})(x)|x_m(x)|
\]

\[
\leq \sum_{x \in \mathcal{S}_m} (Kh)^n \tau \left( \frac{|f_m(x)|}{(n+1) \mathcal{D}^*_m} \right)^{n+1}.
\]

(4.8)

(Note that, by virtue of condition (2.1), the extreme points of \(\hat{\Omega}_h\) lie in \(\Omega^0_m, \forall m\)). Summing (4.8) from \(m = 1\) to \(N\) and using \(v_0 = 0\) we thus obtain

\[
\sum_{x \in \Omega_h} v_N(x)|x_N(x)| \leq \sum_{m=1}^{N} \sum_{x \in \mathcal{S}_m} (Kh)^n \tau \left( \frac{|f_m(x)|}{(n+1) \mathcal{D}^*_m} \right)^{n+1}.
\]

(4.9)

Hence we conclude from Lemma 3.2,

\[
\max_{\Omega_h} v_N \leq \frac{1}{(n+1)} (\omega^*)^n \frac{1}{(n+1)} (KR)^{n+1} \times
\]

\[
\times \left\{ \sum_{m=1}^{N} \sum_{x \in \mathcal{S}_m} h^n \tau \left( \frac{|f_m(x)|}{\mathcal{D}^*_m} \right)^{n+1} \right\}^{\frac{1}{n+1}}
\]

(4.10)

and the estimate (2.9) for the case \(b = c = 0\).
To treat the general case, we introduce a modified mesh function $\bar{u}$ and corresponding operators $\mathcal{F}_a$ defined by

$$\bar{u}(x, t) = e^{-At} u(x, t)$$

$$\mathcal{F}_a \bar{u}(x, t) = (1 - \alpha) e^{A\tau} L_h \bar{u}(x, t) +$$

$$+ \alpha L_h \bar{u}(x, t - \tau) - \delta_\tau^{-} \bar{u}(x, t), \quad (4.11)$$

where $A$ is a non-negative constant to be determined later. Since

$$L_h \bar{u}(x, t) = e^{-At} L_h u(x, t),$$

$$L_h \bar{u}(x, t - \tau) = e^{-A(t - \tau)} L_h u(x, t - \tau)$$

$$\delta_\tau^{-} \bar{u}(x, t) = e^{-A(t - \tau)} \delta_\tau^{-} u(x, t) - \frac{1}{\tau} (e^{\tau A} - 1) \bar{u}(x, t)$$

we obtain, from the differential inequality (2.6),

$$\mathcal{F}_a \bar{u}(x, t) = e^{-A(t - \tau)} \mathcal{F}_a u(x, t) + \frac{1}{\tau} (e^{\tau A} - 1) \bar{u}(x, t)$$

$$\geq - f^-(x, t) + \frac{1}{\tau} (e^{\tau A} - 1) \bar{u}(x, t) \quad (4.12)$$

in $Q^0_{\text{h, } \tau}$. By virtue of conditions (1.6), (1.8), it follows that the operator $\mathcal{F}_a$ given by

$$\mathcal{F}_a \bar{u} = \mathcal{F}_a u - \frac{1}{\tau} (e^{\tau A} - 1) \bar{u}$$

is of positive type provided the analogue of (1.9) holds, that is

$$\tau \{ \alpha c(x, t - \tau) + e^{\tau A}(1 - \alpha) c(x, t) \} \leq e^{\tau A} - 1. \quad (4.13)$$

Clearly, (4.13) will hold for some constant $A$ if $\tau(1 - \alpha) c < 1$, that is if (2.6) holds. But if (1.6) (1.8) hold and $\mathcal{F}_a$ is nondegenerate in the sense that $a(x, t, y) > 0$ for some $y$, then $\tau \alpha c > -1$ by (1.8) and this becomes a necessary condition for (4.13). Accordingly, (1.6), (1.8) and (2.6) are both necessary and sufficient conditions for the operator $\mathcal{F}_a$ to be of positive type for some constant $A$.

Returning to the proof of Theorem 2.1, we now define spatial mesh functions $\bar{u}_m, v_m$ by

$$\bar{u}_m = u(x, m\tau), \quad v_m(x, m\tau) = \max_{j \leq m} (\bar{u}_m)^+(x) \quad (4.14)$$

and let $\Gamma^+_m, \mathcal{F}_m$ be as before. Setting

$$b_m(x, y) = b(x, y, m\tau), \quad \xi_m(x) = \xi(x, m\tau), \quad \psi_m(x, y) = \psi(x, y, m\tau),$$

$$\mathcal{M}^2 \text{ AN Modélisation mathématique et Analyse numérique} \quad \text{Mathematical Modelling and Numerical Analysis}$$
together with
\[(\alpha_m, \beta_m, \kappa_m) = (1 - \alpha) e^{\tau_A} (a_m, b_m, c_m) + \alpha (a_{m-1}, b_{m-1}, c_{m-1}),\]
we then obtain, in place of (4.3), using the positive type condition (1.6),
\[
\sum \alpha_m(x, y) \delta_y^2 v_m(x) + \sum \beta_m(x, y) \delta_y v_m(x) + \kappa_m(x) v_m(x) \geq
\]
\[
\geq \bar{F}_\alpha \tilde{u}(x, m\tau) + \left\{ \frac{1}{\tau} + \alpha \left( -2 \sum \frac{d_{m-1}(x, y)}{|y|^2} + c_{m-1}(x) \right) \right\} \times
\]
\[
\times (v_m - v_{m-1})(x)
\]
\[
\geq \frac{\gamma_{m-1}(x)}{\tau} (v_m - v_{m-1})(x) - f_m(x) + \frac{1}{\tau} (e^{\tau A} - 1) v_m(x),
\]
whenever \(v_m(x) > v_{m-1}(x)\). Now for each \(x \in \Gamma^+_m\), there exists a vector \(p \in \chi_m\), and consequently for each \(x \neq 0\), number \(r_y \in [0, 1]\) such that
\[
p_y = \frac{p \cdot y}{|y|} = r_y \delta_y^+ v_m(x) + (1 - r_y) \delta_y^- v_m(x).
\]
Thus,
\[
\delta_y v_m(x) = \frac{1}{2} (\delta_y^+ + \delta_y^-) v_m(x)
\]
\[
= p_y + \left( r_y - \frac{1}{2} \right) (\delta_y^+ + \delta_y^-) v_m(x),
\]
\[
= p_y - \left( r_y - \frac{1}{2} \right) |y| \delta_y^2 v_m(x).
\]
Therefore, since \(\delta_y^2 v_m(x) \leq 0\) in \(\Gamma^+_m\), we obtain from (4.15),
\[
\sum \tilde{\alpha}_m(x, y) \delta_y^2 v_m(x) + \sum \beta_m(x, y) p_y + \kappa_m v_m(x) \geq
\]
\[
\geq \frac{\gamma_{m-1}(x)}{\tau} (v_m - v_{m-1})(x) - f_m(x) + \frac{1}{\tau} (e^{\tau A} - 1) v_m(x) \tag{4.16}
\]
for all \(x \in \mathcal{G}_m\), where we have set
\[
\tilde{\alpha}_m(x, y) = \alpha_m(x, y) - \frac{|y|}{2} \beta_m(x, y)(\geq 0 \text{ by (2.5)}).
\]
To estimate \(p_y\), we replace the domain \(\Omega\) above by
\[
\tilde{\Omega} = \{ x \in \mathbb{R}^n | \text{dist} (x, \Omega) < kR \}
\]
where \( k \) is a positive constant and \( R \) is the diameter of \( \Omega \). Extending the mesh function \( u \) to vanish outside \( \mathcal{Q}_{h, \tau} \), we clearly arrive at (4.16) again, for the corresponding extended functions \( v_m \), with \( \Omega \) replaced by \( \tilde{\Omega} \). But then we can estimate for \( x \in \Gamma^+_m \), \( p \in \chi_m(x) \),

\[
|p| \leq \frac{v_m(x)}{\text{dist}(x, \partial \tilde{\Omega})},
\]

\[
\leq \frac{v_m(x)}{kR}.
\]

Consequently, from (4.16), we obtain

\[
\sum \alpha_m(x, y) \delta^2 v_m(x) - \frac{\gamma_{m-1}(x)}{\tau} (v_m - v_{m-1})(x) + f_m(x) \geq 0,
\]

\[
\geq \left\{ \frac{1}{\tau} (e^{-\tau} - 1) - \kappa_m(x) - \frac{1}{kR} \sum \beta_m(x, y) \right\} v_m(x),
\]

\[
\geq \left\{ \frac{1}{\tau} (e^{-\tau} - 1) - (1 - \alpha) B_0 e^{-\tau} - \alpha B_0 \right\} v_m(x), \quad \text{(for} \; B_0 = \frac{b_0}{kR} + c_0^0 \text{)},
\]

\[
\geq 0,
\]

(4.17)

provided

\[
(1 - \alpha) \tau B_0 < 1, \quad A \geq \frac{B_0}{1 - (1 - \alpha) \tau B_0}.
\]

(4.18)

Invoking (2.6), we can satisfy (4.18) by fixing \( k \) and \( A \) such that

\[
k \geq \frac{(1 + \varepsilon)(1 - \alpha) \tau b_0}{\mu R}, \quad A \geq \frac{1 + \varepsilon}{\varepsilon \mu} \left( \frac{b_0}{kR} + c_0^0 \right)
\]

(4.19)

for some \( \varepsilon > 0 \). With these choices of \( k \) and \( A \), we thus obtain the difference inequality (4.5) with \( \alpha_m \) replaced by \( \bar{\alpha}_m \) and the estimate (4.10) follows as before. Returning to our original function \( u \), we then conclude the estimate,

\[
\max_{\mathcal{Q}_{h, \tau}} u \leq \frac{1}{n + 1} \omega_n \sum_{n+1}^n \left[ K(k + 1) R \right]^{n+1} e^{\frac{1}{\mu R} \| f/\mathcal{D}^* \|_{L^{n+1}(\mathcal{G})}},
\]

(4.20)

where \( k \) and \( A \) are given by (4.19). Furthermore, by appropriate choice \( k \approx b_0 T / \mu R \), we may write (4.20) in the form

\[
\max_{\mathcal{Q}_{h, \tau}} u \leq C_0 (n) \left( \frac{n}{n+1} \right)^{\frac{n}{n+1}} \left( R + \frac{b_0 T}{\mu} \right)^{\frac{n}{n+1}} \times
\]

\[
\times \exp \left[ C_1 (n) T / \mu \right] \| f/\mathcal{D}^* \|_{L^{n+1}(\mathcal{G})},
\]

(4.21)
where $C_0$ and $C_1$ are positive constants. This completes the proof of Theorem 2.1.

Remarks:

(i) It is clear from the above proof that the constant $K$ in the estimates (2.9), (4.10), (4.20), (4.21) can be replaced by

$$K = \max_{Q_{h, \tau}} |y^i|$$

$$i = 1, \ldots, n$$

(ii) When $\mathcal{D}$ is explicit, that is $\alpha = 1$, we can take $C_1 = \mu = 1$ in (4.21).

(iii) When $b_0 = 0$, we can take $k = 0$, $\tilde{\mathcal{D}} = \mathcal{D}$, $C_1 = 1$ so that the estimate (4.21) reduces to

$$\max_{Q_{h, \tau}} u \leq C_0(n)(KR)^{-n+1} \exp[c_0 T/\mu] \left\| f/\mathcal{D}^* \right\|_{L_{n+1}(\mathcal{G})}.$$  \hspace{1cm} (4.22)

(iv) Utilizing the above case, $b_0 = 0$, and following the proof of Theorem 2.1, we obtain in the general case,

$$\max_{Q_{h, \tau}} u \leq C_0(n)(K(k + 1)R)^{-n+1} \exp[c_0 T/\mu] \cdot$$

$$\left( \left\| f/\mathcal{D}^* \right\|_{L_{n+1}(\mathcal{G})} + \frac{\max_{Q_{h, \tau}} u^+}{kR} \left\| b/\mathcal{D}^* \right\|_{L_{n+1}(\mathcal{G})} \right).$$  \hspace{1cm} (4.23)

By appropriate choice of $k$, we then conclude the estimate

$$\max_{Q_{h, \tau}} u \leq C \left( R^{-n+1} + \left\| b/\mathcal{D}^* \right\|_{L_{n+1}(\mathcal{G})} \right) \left\| f/\mathcal{D}^* \right\|_{L_{n+1}(\mathcal{G})}.$$  \hspace{1cm} (4.24)

where now $C$ depends on $n$, $K$ and $c_0 T/\mu$.

5. SEMIDISCRETE SCHEMES

By letting either of the parameters $h$, $\tau$ tend to zero, we can recover estimates for semidiscrete schemes. For a continuous time scheme, we consider the spatially discrete mesh $E = E_h = \mathcal{Z}_h \times \mathbb{R}$, with mesh function $u \in \mathcal{M}(E)$ assumed to be absolutely continuous with respect to time. The operator $\mathcal{D} = \mathcal{D}_h$ is defined by

$$\mathcal{D} u(x, t) = L_h u(x, t) - D_t u,$$  \hspace{1cm} (5.1)
for almost all \( t \), and our hypotheses on \( \mathcal{L} \) reduce to (1.6), (2.1) with \( \mathcal{D}^* = \mathcal{D}_0^* \) defined by

\[
\mathcal{D}^*(x, t) = \left( \prod_{i=1}^{n} \lambda_i(x, t) \right)^{(n+1)}
\]

The discrete parabolic interior and boundary of the cylinder \( Q_h = Q_h \times (0, T] \), corresponding to \( \mathcal{L} \), are then defined by

\[
Q_h^0 = \{ (x, t) \in Q_h \mid a(x, t, y) = 0 \ \forall x + y \notin \Omega_h \}
\]

\[
Q_h^b = \overline{Q}_h - Q_h^0.
\]

The increasing upper contact set \( \mathcal{S} \) of the mesh function \( u \) is defined as before. Corresponding to Theorem 2.1, we then have the following estimate.

**Theorem 5.1:** Let \( u \) be a space-time mesh function in the cylinder \( Q_h \), satisfying the differential-difference inequality,

\[
\mathcal{L}u = f \quad \text{in} \quad Q_h^0,
\]

together with the boundary conditions,

\[
u \equiv 0 \quad \text{in} \quad Q_h^b.
\]

where \( f \) is a mesh function satisfying \( f/\mathcal{D}^* \in L^{n+1}(\mathcal{S}) \). Then we have the estimate,

\[
\max_{Q_h} u \leq CR \frac{n+1}{n} \left\| f/\mathcal{D}^* \right\|_{L^{n+1}(\mathcal{S})},
\]

where \( C \) depends on \( n, K, b_0 T/R, c_0^+ T \) and \( R = \text{diam} \Omega \).

The norm in (5.4) is defined by

\[
\left\| g \right\|_{L^p(\mathcal{S})} = \left\{ \int_0^T \sum_{x \in D_h} h^n \left| \chi_{\mathcal{S}} g(x, \tau) \right|^p \, dx \right\}^{1/p}
\]

for \( g = f/\mathcal{D}^* \), \( p = n + 1 \), where \( \chi_{\mathcal{S}} \) denotes the characteristic function of \( \mathcal{S} \) in \( Q_h \). Theorem 5.1 follows from Theorem 2.1 with \( \alpha = 0 \), by sending \( \tau \) to zero and observing that we may express (5.2) in the integral form,

\[
\frac{1}{\tau} \int_{t - \tau}^t \int_{Q_h} u(x, s) \, ds - \delta_t^- u(x, t) \equiv \frac{1}{\tau} \int_{t - \tau}^t f(x, s) \, ds
\]
for all \((x, t) \in Q_0^r\), \(t \equiv \tau > 0\). Alternatively, it can be proved directly from the spatially discrete version of the identity (3.4) and Lemma 3.2. The remarks at the end of Section 4, with \(\alpha = 0\), \(\tau \to 0\) also apply here.

When we let the spatial mesh length \(h\) tend to zero, we obtain a system of elliptic operators of the form

\[
\mathcal{L}_\alpha u(x, t) = (1 - \alpha) Lu(x, t) + \alpha Lu(x, t - \tau) - \delta^- u(x, t) \tag{5.6}
\]

where now \(E = \mathbb{R}^n \times \mathbb{Z}_r\) and

\[
Lu(x, t) = \sum_y a(x, y, t) D^2_y u(x, y) + \sum_y b(x, y, t) D_y u(x, t) + c(x, t) u(x, t), \tag{5.7}
\]

where \(\hat{y} = y/|y|\) and the first and second spatial derivatives of the mesh function \(u\) are assumed to exist in a reasonable sense, for example \(u_m \in C^2(\mathbb{R}^n)\) for each \(m\), where \(u_m(x) = u(x, m\tau)\). In order to fulfill conditions (1.6), (2.1), (2.3), (2.6) as \(h \to 0\), we clearly must restrict to the implicit case \(\alpha = 0\), whence we take

\[
\mathcal{L} u(x, t) = Lu(x, t) - \delta^- u(x, t) \tag{5.8}
\]

and conditions (1.6), (2.1), (2.6) reduce to

\[
a(x, y, t) \equiv 0, \quad a(x, y, t) \equiv \lambda, (x, t) > 0, \tag{5.9}
\]

\[
\tau c(x, t) \leq 1 - \mu. \tag{5.10}
\]

Utilizing the representation of Motzkin-Wasow [8] (see also [6]), we may replace (5.7) by any uniformly elliptic operator \(L\) of the form

\[
Lu(x, t) = a^{ij}(x, t) D_{ij} u(x, t) + b^i(x, t) D_i u(x, t) + c(c, t) u(x, t) \tag{5.11}
\]

satisfying (5.10) and deduce an appropriate analogue of Theorem 2.1, by letting \(h \to 0\). However the proof of Theorem 2.1 can be applied directly to the operators \(\mathcal{L}\), similar to the approach in [4], to get results for non-uniformly parabolic operators. Letting \(Q_\tau = \Omega \times \{m\tau\}_{m=1}^N\), we assume that the operator \(L\) is elliptic in \(Q_\tau\) for each \(t\), that is the coefficient matrix \([a^{ij}]\) is positive for all \(x, t \in Q_\tau\), and write

\[
\mathcal{D}^* = (\det [a^{ij}])^{\frac{1}{n+1}}, \quad b_0 = \max_{Q_\tau} |b|, \quad c_0^+ = \max_{Q_\tau} c^+.
\]

Corresponding to Theorem 2.1, 5.1, we now have the following discrete time estimate.

vol. 27, n° 6, 1993
THEOREM 5.2: Let \( u, f \) be mesh functions on \( Q_\tau \), with \( u_m \in C^2(\Omega) \cap C^0(\overline{\Omega}) \), \( f_m \in L^{n+1}(\Omega) \) for each \( n = 1, \ldots, N \), satisfying the differential-difference inequality
\[
\mathcal{D} u \geq f \quad \text{in} \quad Q_\tau ,
\] (5.12)
together with the boundary condition
\[
u_m = 0 \quad \text{on} \quad \partial \Omega , \quad u_0 = 0 , \quad m = 1, \ldots, N .
\] (5.13)

Then we have the estimate
\[
\sup_{Q_\tau} u \leq CR^{n+1} \left\| f/\mathcal{D}^* \right\|_{L^{n+1}(\mathcal{S})}
\] (5.14)

where \( C \) is a constant depending only on \( n, \mu, b_0 T/R, c_0 R \), \( \mathcal{S} \) denotes the increasing-upper contact set of \( u \) and \( R = \text{diam} \Omega \).

The norm in (5.14) is defined by
\[
\|g\|_{L^p(\mathcal{S})} = \left\{ \int_{\Omega} \sum_{m=1}^N \tau \left| \chi_{\mathcal{S}} g(x, m\tau) \right|^p dx \right\}^{1/p}
\]
for \( g = f/\mathcal{D}^* \), \( p = n + 1 \), where \( \chi_{\mathcal{S}} \) denotes the characteristic function of \( \mathcal{S} \) in \( Q_\tau \). Corresponding remarks to Remarks (iii) and (iv) at the end of Section 4 also apply here. In order to directly adapt our previous proof, we also use that the concave hull of a function \( u \in C^2(\Omega) \) belongs to \( C^{1,1}(\Omega) \), ([9], [10]). By sending \( \tau \to 0 \) in Theorem 5.2 we obtain the estimates of [4, 9, 10, 11], but these can also be deduced directly from (3.4) and Lemma 3.2.
