APPROXIMATION OF THE ARCH PROBLEM BY RESIDUAL-FREE BUBBLES

A. AGOUZAL\textsuperscript{1} AND M. EL ALAMI EL FERRICHA\textsuperscript{2}

Abstract. We consider a general loaded arch problem with a small thickness. To approximate the solution of this problem, a conforming mixed finite element method which takes into account an approximation of the middle line of the arch is given. But for a very small thickness such a method gives poor error bounds. The conforming Galerkin method is then enriched with residual-free bubble functions.

Résumé. On considère un problème de déplacement d’une arche chargée et de faible épaisseur. Pour approcher la solution de ce problème, on donne une méthode d’éléments finis Galerkin mixte conforme qui tient compte d’une approximation de la forme de l’arche. Cependant une application directe d’une telle méthode ne donne pas de résultat de convergence satisfaisant pour une faible épaisseur. On propose d’enrichir cette méthode par des fonctions bulles résiduelles.

Mathematics Subject Classification. 65N12.

1. INTRODUCTION

We are interested with a numerical analysis of a general arch problem with a small thickness. The elastic, clamped and loaded arch is studied by following the Budiansky-Sander’s model in linearized elasticity. The variable considered herein is the displacement of the arch under the potential energy of exterior forces. The shape of (the middle line) of the arch is assumed to be represented by a smooth function $\Phi$. The coefficients, in the state equation governing this problem, depend on $\Phi$ and on its third derivative. Following Lods [18] we give a mixed formulation that is equivalent to the state equation in which the primitive variables are the components of the displacement vector in a fixed basis, the rotation of the normal vector and the membrane energy. The coefficients of this reformulated problem only depend on $\Phi$ and on its first derivative. We explicitate the dependence of these coefficients on a critical parameter that is the thickness of the arch. The resulting problem fit into a singularly perturbed one. For the discrete problem, following Bernadou-Ducatel [5], we approach the arch by straight beam elements of small length. But, when the thickness is very small, numerical results obtained from commonly used standard finite element method, deteriorate. Interesting study of this phenomenon has been performed by Habbal and Chenais in [17] where it is proved by a non-conforming finite elements that if the mesh size is taking in the order of the square of the thickness, the convergence is insured. We may also mention that, a precise mathematical meanings for locking and robustness phenomenon are giving by Babuska

Keywords and phrases. Mixed method, Lagrange multipliers, conforming approximations, residual-free-bubble.

and Suri in [3]. To complete we notice that a study of the numerical behaviour is performed in [12] by Chenais
and Paumier for a class of elliptic problem in which a small parameter is involved, the computation of elastic
arches is analyzed using this mathematical framework and general conditions ensuring uniform convergence of
a numerical scheme, with respect to the thickness, are given.

In this paper, we consider the finite element method where the finite-dimensional space used consists of
piecewise polynomials enriched with bubble functions (see [4,16,21,22]). More precisely our computed solution
is the sum of a piecewise polynomial and a bubble function that vanishes on the boundary of each element. We
shall concentrate on the variant of this method where the bubbles are residual-free (see [21,22]). For piecewise
linear elements considered the bubbles are exactly computed. Since these functions vanish on the boundary of each
element, they can be eliminated or statically condensed. The discrete problem is finally written in terms of the
classical polynomial-based test space.

The structure of the paper is as follows: in the next section we consider the continuous arch problem. We
introduce a mixed formulation with Lagrange multipliers where the new unknowns are considered. Following
Lods [18] we establish that this mixed formulation is equivalent to the usual state equation governing the arch
problem. In the remainder of this section, we consider \( \varepsilon \), the thickness of the arch, as a small parameter of
perturbation. We explicitate the dependence of the coefficients of the variational formulation on \( \varepsilon \), we then
concentrate on the resulting perturbed problem for which the key conditions of Brezzi’s theorem are given. In
Section 3 we first consider the discrete problem obtained from a direct application of the Galerkin method and
from an approximation by interpolation of the arch. Consistency error estimates are proved. The stability
conditions, with associated constants depending on \( \varepsilon \), are then established. Some error bounds are given.
Thereafter we introduce the residual-free bubbles technique, we calculate the bubble functions associated to
piecewise linear elements, then we use the static condensation procedure to obtain the new discrete problem. Finally,
we report on some numerical simulations that illustrate the suitability of the method with bubbles presented
herein.

2. THE CONTINUOUS PROBLEM

2.1. The state equation

The shape of the arch is represented by a function \( \Phi \) of the space:

\[ \Lambda_s = \{ \Phi \in W^{s+1,\infty}(I) \text{ such that } \Phi(0) = \Phi(l) = 0 \} \]

where \( l \) is the depth of the arch, \( I = [0, l] \) and \( s \geq 0 \) an integer. If \( L \) is the length of the arch and \( e \) its thickness,
the mean surface is:

\[ \omega = \{(x, y, z) \in \mathbb{R}^3, x \in I, y = \Phi(x) \text{ and } z \in [0, L]\} . \]

If \( \vec{n}(m) \) denotes the unit normal to the surface \( \omega \) at the point \( m \), the arch is the domain:

\[ \Omega = \{ m + x_3 \vec{m}(m), \ m \in \omega; \ -\frac{e}{2} < x_3 < \frac{e}{2} \} . \]

In the setting of Budiansky-Sanders model in linear elasticity theory (see [10]), the displacement at a point
\( M \) of \( \Omega \) is entirely determined by the displacement at a point \( m \) of the mean surface. Since the loading is
invariant on the \( oz \)-axis, the displacement vector belongs to the \((x, y)\)-plane. The problem is then reduced to a
one dimensional problem. The displacement of a point \((x, \Phi(x))\) is marked by its pair of tangential and normal
components in the local basis \((\vec{t}(\Phi), \vec{n}(\Phi))\):

\[ u(x) = u_1(x) \vec{t}(\Phi)(x) + u_2(x) \vec{n}(\Phi)(x) . \]
Where, with \((e_1, e_2)\) the canonical basis of \(\mathbb{R}^2\), \(\Phi' = \frac{d\Phi}{dx}\) and \(S(\Phi) = \sqrt{1 + \Phi'^2}\):

\[
\mathcal{T}'(\Phi) = \frac{1}{S(\Phi)} (e_1 + \Phi' e_2), \quad \mathcal{n}(\Phi) = \frac{1}{S(\Phi)} (-\Phi' e_1 + e_2).
\]

The arch being clamped, the pair \(u = (u_1, u_2)\) of components belongs to the admissible displacement space (see [18])

\[
W = H_0^1(I) \times H_0^1(I)
\]

where \(H_0^1(I)\) and \(H_0^3(I)\) are usual Sobolev spaces. Naturally the displacement \(u\) depends on the function \(\Phi\). From the virtual work principle \(u\) satisfies the state equation (see [5]):

\[
u \in W \quad c(\Phi; u, v) = l(\Phi; v)
\]

where the energy \(c\) of the arch is given by:

\[
c(\Phi; u; v) = E c l \int_0^l \eta(\Phi; u) \eta(\Phi; v) s(\Phi) \, dx + \frac{E c^3 l}{12} \int_0^l k(\Phi; u) k(\Phi; v) s(\Phi) \, dx
\]

with \(E\): the Young modulus, \(\eta\): the membrane energy and \(k\): the bending energy, respectively given by:

\[
\eta(\Phi; v) = \frac{1}{S(\Phi)} e_1' + \frac{1}{R(\Phi)} e_2, \quad k(\Phi; v) = \left(\frac{\theta(\Phi; v)}{S(\Phi)}\right)'
\]

the curvature \(\frac{1}{R(\Phi)}\) of \(\omega\) and the rotation of the normal vector \(\theta(\Phi; v)\) are defined by:

\[
\frac{1}{R(\Phi)} = -\frac{\Phi''}{S(\Phi)^3} \quad \text{and} \quad \theta(\Phi; v) = \frac{v_1}{R(\Phi)} - \frac{v_2'}{S(\Phi)}.
\]

The virtual work of exterior load is (with \(\rho\) the density of the material):

\[
l(\Phi, v) = -\int_0^l \rho e(\Phi' v_1 + v_2) \, dx.
\]

### 2.2. The mixed continuous formulation

We fix notation and functional setting that shall be used in the analysis below.

Let \((\beta, \gamma)\) denote the pair of components of the displacement vector in the fixed basis \((e_1, e_2)\). Designate by \(\Theta\) and \(\eta\) respectively the rotation of the normal vector and the membrane energy; the new unknown vector is: \((\beta, \gamma, \Theta, \eta) \in (H_0^1(I))^3 \times L^2(I)\). Let \(u = (\beta, \gamma, \Theta, \eta)\) be the primal unknown and \(v = (\beta, \gamma, \Theta, \eta)\) a generic variable corresponding to \(u\). Denote by \(p = (p_1, p_2)\) the unknown in the space of Lagrange multipliers and \(q = (q_1, q_2)\) a generic variable associated. We employ the the conventional spaces \(L^2(\Omega)\), \(H^2(\Omega)\), \(H_0^3(\Omega)\) and \(W^{s,\infty}(\Omega)\) with their classical norms: \(\|\cdot\|_{0,\Omega} = \|\cdot\|_{0,\Omega}\) and \(\|\cdot\|_{s,\infty,\Omega}\): as usual \((a, b)_{\Omega} = \int_{\Omega} ab \, dx\). For brevity we drop the subscript \(\Omega\) when \(\Omega = I\). Finally we introduce the spaces \(V = (H_0^1(I))^3 \times L^2(I)\) and \(\Sigma = L^2(I) \times L^2(I)\) equipped respectively of the norms:

\[
\|v\|^2_V = \|\beta\|^2_1 + \|\gamma\|^2_1 + \|\Theta\|^2_1 + \|\eta\|^2_0
\]

\[
\|q\|^2_{\Sigma} = \|q_1\|^2_0 + \|q_2\|^2_0.
\]

Now, let us recall some results given by Lods in [18].
Proposition 1. Assume that $\Phi \in \Lambda_s$. Let $v = (v_1, v_2)$ belong to the space $W$ then the following equalities hold in $L^2(I)$:

$$
\beta' = \theta \Phi' + \eta \tag{7}
$$

$$
\gamma' = -\theta + \Phi' \gamma' \tag{8}
$$

where $\beta e_1 + \gamma e_2 = v_1 \tilde{e}(\Phi) + v_2 \tilde{n}(\Phi)$, $\theta = \theta (v; \Phi)$ and $\eta = \eta (v; \Phi)$.

Variational formulation. Define the subspace

$$
K(\Phi) = \{ v \in V \text{ such that } b(v; \mu) = 0 \quad \forall \mu \in \Sigma \}
$$

where the continuous bilinear form $b(\Phi; \cdot , \cdot)$ is given by:

$$
b(v, \mu) = \int_0^l \mu_1 (\beta' - \theta \Phi' - \eta) \, dx + \int_0^l \mu_2 (\gamma' - \theta + \Phi' \gamma) \, dx \quad \forall \mu = (\mu_1, \mu_2) \in \Sigma
$$

then we have:

Proposition 2. Assume that $\Phi \in \Lambda_s$, then the mapping:

$$
F^\Phi : W \longrightarrow K(\Phi)
$$

$$
v = (v_1, v_2) \longmapsto (\beta, \gamma, \theta, \eta)
$$

where $\beta = \beta(\Phi; v)$ and $\gamma = \gamma(\Phi; v)$ is an isomorphism.

By using the isomorphism $F^\Phi$, the state equation (2) is equivalent to the following problem (see [18]): find $u = (\beta, \gamma, \theta, \eta) \in K(\Phi)$ such that:

$$
a(\Phi; u, v) = l(v; \Phi), \quad \forall v \in K(\Phi) \tag{9}
$$

where the bilinear form $a(\Phi; \cdot , \cdot)$ and the linear form $l(\Phi; \cdot)$ are respectively given by

$$
a(u, v) = Eel \int_0^l \eta S(\Phi) \, dx + \frac{Ee^3}{12} \int_0^l \theta' \Phi' \cdot \frac{1}{S(\Phi)} \, dx \tag{10}
$$

$$
l(v) = -p e \int_0^l \gamma S(\Phi) \, dx. \tag{11}
$$

By standard arguments, we can set the variational problem with Lagrange multipliers as: find $u = (\beta, \gamma, \theta, \eta) \in V$ and $p = (p_1, p_2) \in \Sigma$ such that:

$$
(P) \quad \left\{
\begin{array}{l}
a(\Phi; u, v) + b(\Phi; v, p) = l(v; \Phi) \quad \forall v = (\beta, \gamma, \theta, \eta) \in V \\
b(\Phi; u, q) = 0 \\
\end{array}
\right. \quad \forall q = (q_1, q_2) \in \Sigma
$$

where the bilinear form $b(\Phi; \cdot , \cdot)$ is given by

$$
b(v, q) = \int_0^l q_1 (\beta' - \theta \Phi' - \eta) \, dx + \int_0^l q_2 (\gamma' - \theta + \Phi' \gamma) \, dx.
$$
Now, denoting by $A$ and $B$ the operators associated to the forms $a(.,.)$ and $b(.,.)$, we obtain from problem $(P)$ the following Euler Lagrange equations:

$$
Au + B^* p = f \quad (12)
$$

$$
Bu = 0 \quad (13)
$$

with:

$$
Au = \begin{pmatrix}
0 \\
0 \\
-\frac{E e^3 l}{12} \left( \frac{\varphi'}{s(\Phi)} \right)'
\end{pmatrix} ; \quad B^* p = \begin{pmatrix}
-p_1' \\
-p_2' \\
-p_1 \Phi' + p_2 \\
-p_1 - \Phi \eta
\end{pmatrix} ; \quad f = \begin{pmatrix}
0 \\
\rho S(\Phi) \\
0 \\
0
\end{pmatrix}
$$

and

$$
Bu = \begin{pmatrix}
\beta' - \partial \Phi' - \eta \\
\gamma' + \partial - \Phi' \eta
\end{pmatrix}.
$$

The subsequent theorem establishes the equivalence between the mixed problem and the state equation (2), we have (see [18]).

**Theorem 3.** Assume that $\Phi \in \Lambda_x$, then problem $(P)$ admits a unique solution $(u, p)$ and $u_\infty = (F - \Phi) u$ is the solution of the state equation.

### 2.3. The perturbed problem

Explicitating the dependence of the coefficients in equations of problem $(P)$ on a small parameter $\varepsilon = \frac{\xi}{l}$ (the rigidity), taking, for simplicity, $l = 1$ and dividing by $E$ the two members of its first equation, problem $(P)$ becomes:

$$(P_\varepsilon) \left\{ \begin{array}{l}
a_\varepsilon (w, \tau) + b(\tau, p) = l (\tau) \quad \forall \tau \in V \\
b(w, q) = 0 \quad \forall q \in \Sigma
\end{array} \right.
$$

where

$$
a_\varepsilon (w, \tau) = \varepsilon \int_0^1 \eta \sqrt{S(\Phi)} \, dt + \frac{\varepsilon^3}{12} \int_0^1 \eta \frac{\varphi'}{S(\Phi)} \, dt 
$$

$$
b(\tau, q) = \frac{1}{EL} \left\{ \left( \frac{\beta' - \partial \Phi' - \eta}{\eta} q_1 + \frac{\gamma' + \partial - \Phi' \eta}{\eta} q_2 \right) \right\}
$$

and

$$
l (\tau) = -\rho (\gamma, S(\Phi))_{0, l}
$$

with $l = (0, 1)$. To examine existence and uniqueness of solution for $(P_\varepsilon)$, the strategy is to fulfill the two key stability conditions: ($K$ - ellipticity and LBB) (see [2] and [6]);

$$(S_1) \quad a(v, v) \geq C_1 \|v\|^2_V \quad \forall v \in K
$$

$$(S_2) \quad \sup_{\tau \in V} \frac{b(\tau, q)}{\|\tau\|^2_V} \geq C_2 \|q\|^2_\Sigma \quad \forall q \in \Sigma
$$
this has been done in the proof of the previous theorem. We observe that for \( \varepsilon > 0 \) the form \( a(\ldots) \) is \( K \)-elliptic and the problem is well-posed. However for \( \varepsilon = 0 \) problem \( (P_0) \) is not solvable. From now on, we shall deal with problem \( (P_\varepsilon) \) for \( 0 < \varepsilon \ll 1 \) (the numerically more delicate case) which can be written as:

\[
\begin{align*}
    a_\varepsilon(w, \tau) + b_\varepsilon(\tau, p) &= l(\tau) \quad \forall \tau \in V \\
    b_\varepsilon(w, q) &= 0 \quad \forall q \in \Sigma
\end{align*}
\]  

(14)

where:

\[
\begin{align*}
    a_\varepsilon(w, \tau) &= \int_0^1 \eta \psi(s(\Phi)) \, dt + \frac{1}{12} \varepsilon^2 \int_0^1 \psi' \Phi' \cdot \frac{1}{s(\theta)} \, dt \\
    b_\varepsilon(\tau, q) &= \frac{1}{\varepsilon E} \left\{ (\Phi' - \theta \Psi' - \psi, q_1) + (\Phi' + \theta - \Psi' \psi, q_2) \right\}
\end{align*}
\]

and

\[
l(\tau) = -\rho \int_0^1 \frac{1}{2} \nabla S(\Phi) \, dt.
\]

We now only explicitate the dependence on \( \varepsilon \) of the constants \( C_1 \) and \( C_2 \) appearing in conditions \((S_1)\) and \((S_2)\) respectively, which is easy.

**Lemma 4.** There exists a constant \( C > 0 \) which depends on \( \Phi \) such that:

\[
a_\varepsilon(\tau, \tau) \geq C\varepsilon^2 \|
\tau\|^2, \quad \forall \tau \in K(\Phi).
\]  

(15)

**Lemma 5.** There exists a constant \( C > 0 \) independent of \( \varepsilon \) such that:

\[
\sup_{\tau \in V} \frac{b(\tau, q)}{\|
\tau\|_V} \geq C\varepsilon \|
q\|_\Sigma \quad \forall q \in \Sigma.
\]  

(16)

### 3. The Discrete Problem

Let us first fix notation and finite-dimensional spaces that shall be used throughout: consider \( T_h \) a regular partition (see Ciarlet [13]) of the closed interval \( I = [0, 1] \) into elements \( K_i = [x_i, x_{i+1}] \); \( i = 0, N \) such that the mesh parameter, \( h = \max_{1 \leq i \leq N+1} h_i \), with \( h_i = (x_{i+1} - x_i) \) and \( N \geq 1 \) an integer. Let \( P_r(K_i) \) be the space of polynomials of degree less or equal to \( r \) defined on an element \( K_i \). Designate by \( q_h = (q_{h_{1,1}}, q_{h_{1,2}}, q_{h_{1,3}}) \) the primal discrete unknown and by \( q_h = (\beta_h, \gamma_h, \theta_h, \eta_h) \) the corresponding variable. Denote by \( p_h = (p_{h_{1,1}}, p_{h_{1,2}}) \) the unknown in the Lagrange multipliers space and by \( q_h = (q_{h_{1,1}}, q_{h_{1,2}}) \) the associated variable. Let \( M_h^0(I) \) be the space of \( C^{-1} \)-piecewise polynomial interpolations of degree \( l \), i.e.

\[
M_h^0 = \{ \lambda_h \in L^2(I) , \lambda_h |_{K_i} \in P_1(K_i), \ i = 0, N \}.
\]

Let \( W_h^0(I) \) be the space of \( C^0 \)-piecewise polynomial interpolations of degree \( k \) with zero value at \( x = 0 \) and \( x = 1 \), i.e.

\[
W_h^0 = \{ \mu_h \in C(I) , \mu_h |_{K_i} \in P_k(K_i), \ i = 0, N \text{ and } \mu_h(0) = \mu_h(1) = 0 \}.
\]

Consider, for \( k, l \geq 1 \), the finite-dimensional spaces:

\[
V_h = V_h^k = W_h^k \times W_h^k \times W_h^k \times M_h^{k-1}
\]  

(17)

\[
\Sigma_h = \Sigma_h^l = M_h^l \times M_h^l
\]  

(18)

as the discrete spaces of primal and Lagrange multipliers variables respectively.
3.1. The discrete formulation

The method consists to approach the shape function $\Phi$ by its interpolate function $\Phi_h$ on the space $W_h^m$, $(m \leq s)$, and set the discrete problem $(P_h)$ as follows: find $w_h \in V_h$ and $p_h \in \Sigma_h$ such that:

$$a_h (w_h, \tau_h) + b_h (\tau_h, p_h) = l_h (\tau_h) \quad \forall \tau \in V_h$$

(19)

$$b_h (w_h, q_h) = 0 \quad \forall q_h \in \Sigma_h.$$ (20)

Where:

$$a_h (w_h, \tau_h) = \int_0^1 h_0 \eta_0 \frac{S (\Phi_h) dt}{\int_0^1 12 \frac{\theta_h'}{S (\Phi_h)}} dt$$

$$b_h (\tau_h, q_h) = \frac{h_0}{\varepsilon E} (\beta_h - \theta_h \Phi_h' - \eta_h, q_h) + \frac{1}{\varepsilon E} (\gamma_h + \theta_h - \Phi_h'' q_h, q_h)$$

and

$$l_h (\tau_h) = -\rho \left( \tau_h, S (\Phi_h) \right)_{0, I}.$$

These approximations are conforming since we have:

$$W_h^m \subset W^{1, \infty} (I), \quad V_h \subset V \quad \text{and} \quad \Sigma_h \subset \Sigma.$$

We first recall from [18] the following technical result:

Lemma 6. Assume that $\Phi_h$ is an interpolant of $\Phi \in \Lambda_s$ on the space $W_h^m$, $(m \leq s)$, then the subspace:

$$K_h (\Phi_h) = \left\{ v_h = (\beta_h, \gamma_h, \theta_h, \eta_h) \in V_h / b_h (v_h, q_h) = 0 \forall q_h \in \Sigma_h \right\}$$

is nothing but the space of functions $v_h$ such that:

$$\beta_h = \theta_h \Phi_h' + \eta_h \quad \text{and} \quad \gamma_h = -\theta_h + \Phi_h'' \eta_h$$

(21)

otherwise, one has: $K_h (\Phi_h) \subset K (\Phi_h)$.

Lemma 7. Under the same hypotheses as in Lemma 6, the two stability conditions also hold for the approximated bilinear forms $a (\Phi_h; \ldots)$ and $b (\Phi_h; \ldots)$, indeed there exist constants $a_1$ and $a_2$ independents of $h$ and $\varepsilon$ such that for $h \leq h_0$, we have:

$$a_h (\Phi_h; \tau_h, \tau_h) \geq a_1 \varepsilon \| \tau_h \|^2_V \quad \forall \tau_h \in K_h (\Phi_h)$$

(22)

$$\sup_{\tau_h \in V_h} \frac{b (\Phi_h; \tau_h, q_h)}{\| \tau_h \|^2_V} \geq a_2 \frac{\varepsilon}{\varepsilon} \| q_h \|_\Sigma \quad \forall q_h \in \Sigma_h.$$ (23)

Proof. It suffices to remark that $S (\Phi_h) \geq 1$ and that $\frac{1}{S (\Phi_h)}$ is bounded bellow for $h \leq h_0$ with a constant independent of $h$. The proof of estimate (22) is then quite similar to this of estimate (15) in Lemma 4. For the estimate (23), denote for any $t_h \in \Sigma_h$, $t_h^0$ the mean value of $t_h$ i.e. $t_h^0 = \int_0^1 t_h dx$. Now, for $k \geq l - 1$, select, for any $q_h \in \Sigma_h$, $\tilde{\tau} = (s_h, t_h, 0, 0)$ such that:

$$s_h (x) = \int_0^x q_{1h} (\zeta) - q_{1h}^0 \, d\zeta \quad \text{and} \quad t_h (x) = \int_0^x q_{2h} (\zeta) - q_{2h}^0 \, d\zeta$$
so that \( b(\Phi_h; \tilde{\tau}, q_h) = \|q_h\|_\Sigma^2 \) and hence

\[
\varepsilon \sup_{\tau \in V_h} \frac{b(\Phi_h; \tilde{\tau}, q_h)}{\|\tilde{\tau}\|_V} \geq \varepsilon \frac{b(\Phi_h; \tilde{\tau}, q_h)}{\|\tilde{\tau}\|_V} \geq \frac{1}{2} \|q_h\|^2_\Sigma \geq \frac{1}{2} \|q_h\|_\Sigma
\]

yielding \( \alpha_2 = \frac{1}{2} \).

Now, using Lemma 7 and Brezzi’s theorem (see [6]) the following result is immediate:

**Theorem 8.** Assume that \( \Phi \in \Lambda_s \) (\( s \geq 1 \)), then there exists a real \( h_0 > 0 \) such that, for \( h \leq h_0 \), the discrete problem \((P_h)\) admits unique solution \((w_h, p_h)\).

Let us now establish some consistency error estimates:

### 3.2. Consistency error estimates

Assume that \( \Phi \in \Lambda_s \). Let \( \Phi_h \) be the interpolate function of \( \Phi \) on the space \( W^m_h(I) \), (\( m \leq s \)), such that the interpolation error satisfies:

\[
|\Phi - \Phi_h|_1 \leq C h^m |\Phi|_{m+1}
\]

then, with \( C \) a generic constant independent of \( \varepsilon \) and \( h \), the following results hold:

**Lemma 9.** There exists a real \( h_0 > 0 \) such that, for \( h \leq h_0 \), the bilinear form \( a_h(\cdot, \cdot) \) is well defined on \( V \times V \), moreover one has:

\[
|a(\varepsilon w_h, \tau_h) - a_h(w_h, \tau_h)| \leq C h^m \|w_h\|_V \|\tau_h\|_V \quad \forall (w_h, \tau_h) \in V \times V.
\]

**Proof.** On each \( K_i \), we have:

\[
|a(\varepsilon w_h, \tau_h) - a_h(w_h, \tau_h)| \leq \int_{K_i} |\eta_h \eta_h| |S(\Phi) - S(\Phi_h)| \, dt + \frac{\varepsilon^2}{12} \int_{K_i} |\phi_h^i \phi_h^i| \left( \frac{1}{S(\Phi)} - \frac{1}{S(\Phi_h)} \right) \, dt
\]

we will give estimate for each term of the second member of (23). Since the function \( x \rightarrow \sqrt{1 + x^2} \) is globally Lipschitz on \( IR \) with constant 1 we have:

\[
|S(\Phi) - S(\Phi_h)| \leq |\Phi' - \Phi_h'|
\]

and

\[
\left| \frac{1}{S(\Phi)} - \frac{1}{S(\Phi_h)} \right| \leq |S(\Phi) - S(\Phi_h)| \leq |\Phi' - \Phi_h'|
\]

By using the Schwarz inequality we get for the first term:

\[
\int_{K_i} |\eta_h \eta_h| |S(\Phi) - S(\Phi_h)| \, dt \leq |\Phi' - \Phi_h'|_{0,K_i} \|\eta_h\|_{0,K_i} \|\eta_h\|_{0,K_i}.
\]

Now, from the interpolation error we get, with \( C \) a constant independent of \( h \):

\[
\int_{K_i} |\eta_h \eta_h| |S(\Phi) - S(\Phi_h)| \, dt \leq C h^m \|\eta_h\|_{0,K_i} \|\eta_h\|_{0,K_i}.
\]
Similarly, for the second term we obtain:

$$\frac{\varepsilon^2}{12} \int_{K_i} |\theta_h^j q_h^j| \left| \frac{1}{S(\Phi)} - \frac{1}{S(\Phi_h)} \right| dt \leq \frac{\varepsilon^2}{12} |\theta_h|_{1,K_i} |\theta_h^j|_{1,K_i} |\Phi - \Phi_h|_{0,K_i}.$$  

So, from (24) we get:

$$\frac{\varepsilon^2}{12} \int_{K_i} |\theta_h^j q_h^j| \left| \frac{1}{S(\Phi)} - \frac{1}{S(\Phi_h)} \right| dt \leq c h^m \frac{\varepsilon^2}{12} |\theta_h|_{1,K_i} |\theta_h|_{1,K_i}.$$  

Adding and using the Schwarz inequality, we obtain the estimate after summing the integrals over all elements $K_i$.

**Lemma 10.** There exists a real $h_0^2 > 0$ such that, for $h \leq h_0^2$, the bilinear form $b_h (\cdot, \cdot)$ on $V \times \Sigma$ is well defined and:

$$|b_h (\tau_h, q_h) - b (\tau_h, q_h)| \leq C h^m |\tau_h|_V |q_h|_\Sigma \forall \tau \in V_h; \quad \forall q \in \Sigma_h.$$

*Proof.* For any $\tau_h = (\beta_h, \gamma_h, \theta_h, \eta_h) \in V_h$ and any $q_h = (q_{1h}, q_{2h}) \in \Sigma_h$ we have:

$$|b (\tau_h, q_h) - b_h (\tau_h, q_h)| \leq \frac{C}{\varepsilon} \int_0^1 (|\theta_h q_{1h}| |\Phi' - \Phi_h| + |\eta_h q_{2h}| |\Phi' - \Phi_h|) dt.$$  

From (24) and the Schwarz inequality yields:

$$|b (\tau_h, q_h) - b_h (\tau_h, q_h)| \leq C \frac{h^m}{\varepsilon} |\Phi|_{m+1,K} \left( |\theta_h|_{0,K} |q_{1h}|_{0,K} + |\eta_h|_{0,K} |q_{2h}|_{0,K} \right).$$  

Thus, with $C$ a constant which depends on $\Phi$ and doesn’t depend on $\varepsilon$ and $h$:

$$|b (\tau_h, q_h) - b_h (\tau_h, q_h)| \leq C \frac{h^m}{\varepsilon} (|\theta_h|_0 + |\eta_h|_0) (|q_{1h}|_0 + |q_{2h}|_0).$$

**Lemma 11.** There exists a real $h_0^3 > 0$ such that, for $h \leq h_0^3$, the linear form $l_h (\cdot)$ on $V_h$ is well defined and:

$$|l (\tau_h) - l_h (\tau_h)| \leq c h^m |\tau_h|_V \quad \forall \tau \in V_h.$$

*Proof.* For any $\tau_h = (\beta_h, \gamma_h, \theta_h, \eta_h) \in V_h$ we have:

$$|l (\tau_h) - l_h (\tau_h)| \leq \rho \int_0^1 \gamma (S(\Phi) - S(\Phi_h)) dt.$$  

Using the Schwarz inequality and (24) we immediately obtain:

$$|l (\tau_h) - l_h (\tau_h)| \leq C h^m |\Phi|_{m+1} \gamma_0.$$  

3.3. **Accuracy error estimate**

We can now prove the error estimates theorem. Designating by $C$ a generic constant independent of $\varepsilon$ and $h$, the following holds:
Theorem 12. Let, for $\Phi \in \Lambda_s$ $(s \geq 1)$, $(u, p)$ be the solution of problem (P$_2$) and $(u_h, p_h)$ be the solution of problem (P$_h$) then we have:

$$\|u - u_h\|_V \leq C\varepsilon^2 \left\{ \inf_{\tau_h \in V_h} \|u - \tau_h\|_V + \inf_{\tau_h \in V_h} \sup_{v_h \in V_h} \frac{|a_h(\tau_h, v_h) - a(\tau_h, v_h)|}{\|v_h\|_V} \right. \left. + \sup_{v_h \in V_h} \frac{|b_h(v_h, p) - b(v_h, p)|}{\|v_h\|_V} + \sup_{v_h \in V_h} \frac{|l(v_h) - l_h(v_h)|}{\|v_h\|_V} \right\}. \quad (29)$$

Assume that, $u \in \{H^{k+1}(I) \cap H^1_0(I)\}^3 \times H^k(I)$ and $p \in \{H^{l+1}(I) \times H^{l+1}(I)\}$. Let $\tilde{u}_h \in V_h$, $\tilde{p}_h \in \Sigma_h$ and $\Phi_h \in W_h$ be interpolants of $u$, $p$ and $\Phi$ respectively. Assume that the interpolation errors $u - \tilde{u}_h$, $p - \tilde{p}_h$ and $\Phi - \Phi_h$ satisfy

$$\|u - \tilde{u}_h\|_V \leq Ch^k \quad (30)$$

$$\|p - \tilde{p}_h\|_{\Sigma} \leq Ch^{l+1} \quad (31)$$

$$\|\Phi - \Phi_h\|_1 \leq Ch^m \quad (32)$$

then, with $\nu = \min(k, l + 1, m)$:

$$\|u - u_h\|_V \leq C(p, u)\varepsilon^{-2} h^{\nu}. \quad (33)$$

In particular for $m = 1$ (when the arch is approximated by straight beams) we have, for any higher order elements

$$\|u - u_h\|_V \leq C(p, u)\varepsilon^{-2}$$

and hence a locking phenomenon could appear when $(\varepsilon \ll \sqrt{n})$.

Proof. As the problem (P$_h$) satisfies the general hypotheses of Brezzi’s theorem, the technique used to prove estimate (29) is classical (see [8], p. 67). For the usual term $\inf_{\tau_h \in V_h} \|u - \tau_h\|_V$ of the right hand side of inequality (30) the infimum is bounded from above taking $\tau_h = \tilde{\tau}_h$ the $V_h$-interpolate of $\tau$. The additional tree terms which measure the consistency between the original forms and their approximated ones, are given by Lemmas 7 to 9. Indeed from Lemma 7 we have

$$|a(\tilde{u}_h, v_h) - a_h(\tilde{u}_h, v_h)| \leq Ch^m \|\tilde{u}_h\|_V \|v_h\|_V$$

so that

$$\sup_{v_h \in V_h} \frac{|a(\tilde{u}_h, v_h) - a_h(\tilde{u}_h, v_h)|}{\|v_h\|_V} \leq Ch^m \|\tilde{u}_h\|_V. \quad (34)$$

Similarly, by Lemma 8 we have, with $\tilde{q}_h$ the $\Sigma_h$-interpolate of $q$

$$\sup_{v_h \in V_h} \frac{|b_h(v_h, \tilde{q}_h) - b(v_h, \tilde{q}_h)|}{\|v_h\|_V} \leq \frac{Ch^m}{\varepsilon} \|\tilde{q}_h\|_\Sigma. \quad (35)$$

Since the operator of $V_h$-interpolation (resp. $\Sigma_h$-interpolation) satisfy (see [8])

$$\|\tilde{q}_h\|_V \leq C\|q\|_V \quad \text{and} \quad \|\tilde{q}_h\|_\Sigma \leq C\|q\|_\Sigma$$

the error estimate (33) follows by combining (28) to (32) and (33) to (36).
4. THE RESIDUAL-FREE BUBBLES TECHNIQUE

It was established that standard Galerkin method do not be effective to give a suitably approximation of the solution of problem \((P_\varepsilon)\) when \(\varepsilon \ll h\). In order to achieve good approximation properties, we propose to enrich the Galerkin method by residual-free bubbles functions \([22]\). To be more precise, for the given grid \(T_h\), we still employ piecewise linear elements to approach the geometry of the arch, but for approximation of the displacement, we add to the space \(V_h\) of polynomials a space spanned by bubbles functions to recover an augmented test space \(S_h\). The bubble functions are assumed to satisfy the governing differential equations in each element interior subjected to the Dirichlet conditions on each element boundary. Denote:

\[
\begin{align*}
V_l &= W_h^1 \times W_h^1 \times W_h^1 \times W_h^1 \\
\Sigma_l &= \Sigma_h^1
\end{align*}
\]

where \(W_h^1\) and \(\Sigma_h^1\) are defined as in Section 3. Let \(V_h\) and \(\Sigma_h\) designate the spaces spanned by bubbles corresponding to \(V_l\) and \(\Sigma_l\) respectively. The new test spaces are

\[
S_h = V_l \oplus V_h \quad \text{and} \quad \Sigma_h = \Sigma_l \oplus \Sigma_h.
\]

Consequently each \(w_h \in S_h\) and each \(p_h\) of \(\Sigma_h\) is the sum of a polynomial and a bubble component:

\[
w_h = w_l + w_b; \quad p_h = p_l + p_b.
\]

Let us now shed some light on the effect of eliminating the bubble functions by the static condensation procedure. For simplicity writing, we shall drop the subscript \(\varepsilon\) in the forms \(a_{\varepsilon h}(.,.)\) and \(l_{\varepsilon h}(.)\). Consider the problem: find \(w_h \in S_h\) and \(p_h \in \Sigma_h\) such that:

\[
(P_h) : \begin{cases}
a_h(w_h, \tau_h) + b_h(\tau_h, p_h) = l_h(\tau_h) & \forall \tau_h \in S_h \\
b_h(w_h, q_h) = 0 & \forall q_h \in \Sigma_h
\end{cases}
\]

where, with \(w_l = (\beta_l, \gamma_l, \theta_l, \eta_l); \tau_l = (\beta_l, \gamma_l, \theta_l, \eta_l)\); \(w_b = (\beta_b, \gamma_b, \theta_b, \eta_b)\) and \(\tau_b = (\beta_b, \gamma_b, \theta_b, \eta_b)\)

\[
\begin{align*}
a_h(w_h, \tau_h) &= \varepsilon \int_0^1 \eta_h \eta_h S(\Phi_h) \, dt + \frac{\varepsilon^3}{12} \int_0^1 \gamma_h \gamma_h \Phi_h' \Phi_h' \, \frac{1}{S(\Phi_h)} \, dt \\
b_h(\tau_h, q_h) &= \left(\beta_h' - \theta_h \Phi_h' - \eta_h', q_h \right) + \left(\gamma_h' + \theta_h \Phi_h' - \Phi_h q_h, q_h \right) \\
l_h(\tau_h) &= -\varepsilon \int_0^1 \gamma_h \gamma_h S(\Phi_h) \, dt.
\end{align*}
\]

Reporting in \((P_h)\) yields:

\[
\begin{align*}
\forall \tau_l \in V_l \quad \forall \tau_b \in V_b & \quad \forall q_l \in \Sigma_l \quad \forall q_b \in \Sigma_b.
\end{align*}
\]

Now, if we take first \(\tau_l = 0\) and \(q_l = 0\) we get the formulation:

\[
\begin{align*}
a_h(w_b, \tau_b) + b_h(\tau_b, p_b) &= l_h(\tau_b) - a_h(w_l, \tau_b) - b_h(\tau_b, p_l) & \forall \tau_b \in V_b \\
b_h(w_b, q_b) &= -b_h(w_l, q_b) & \forall q_b \in \Sigma_b.
\end{align*}
\]
Equivalently, with $A$ and $B$ the operators associated to the forms $a_h(\cdot, \cdot)$ and $b(\cdot, \cdot)$

\[
a_h(w_h, \tau_b) + b_h(\tau_b, p_b) = (f - Aw_l - B^* p_l, \tau_b) \quad \forall \tau_b \in V_h \tag{37}
\]

\[
b_h(w_h, q_b) = -(Bw_l, q_b) \quad \forall q_b \in \sum_b. \tag{38}
\]

Consequently, for the given $(w_l, p_l) \in V_l \times \Sigma_l$, the pair of bubbles $(w_b, p_b)$ satisfy:

\[
Aw_b + B^* p_b = -Aw_l - B^* p_l - f \quad \text{in } K \tag{36.a}
\]

\[
Bw_b = -Bw_l \quad \text{in } K \tag{36.b}
\]

\[
w_b = p_b = 0 \quad \text{on } \partial K. \tag{36.c}
\]

Selecting $\tau_b = q_b = 0$ in (34) yields:

\[
a_h(w_h + w_l, \tau_l) + b_h(\tau_l, p_l + p_b) = l_h(\tau_l) \quad \forall \tau_l \in V_l \tag{39}
\]

\[
b_h(w_h + w_l, q_l) = 0 \quad \forall q_l \in \sum_l. \tag{40}
\]

Which can be written as:

\[
a_h(w_l, \tau_l) + \langle Aw_b + B^* p_b, \tau_l \rangle + b_h(\tau_l, p_l) = l_h(\tau_l) \quad \forall \tau_l \in V_l \tag{41}
\]

\[
b_h(w_l, q_l) = -b_h(w_b, q_l) \quad \forall q_l \in \sum_l. \tag{37}
\]

Where the term $\langle Aw_b + B^* p_b, \tau_l \rangle$ gives the bubbles contribution to the reduced space formulation.

**Determination of the bubble basis functions.** Let, for $i = 1, n_K$, $\{\Psi_{li}\}$ and $\{p_{li}\}$ be the polynomial local basis corresponding to $V_l$ and $\sum_l$ respectively; $\{\Psi_{bi}, \Psi_{bf}\}$ and $\{p_{bi}, p_{bf}\}$ denote the local basis of bubble functions associated to $V_b$ and $\sum_b$. Problem (36) splits in: find $\Psi_{bi}$ and $p_{bi}$ such that

\[
A\Psi_{bi} + B^* p_{bi} = -A\Psi_{li} + B^* p_l \quad i = 1, n_K \quad \text{in } K \tag{38.a}
\]

\[
B\Psi_{bi} = -B \Psi_{li} \quad i = 1, n_K \quad \text{in } K \tag{38.b}
\]

\[
\Psi_{bi} = p_{bi} = 0 \quad i = 1, n_K \quad \text{on } \partial K \tag{38.c}
\]

and, find $\Psi_{bf}$ and $p_f$ such that

\[
A\Psi_{bf} = -B^* p_l - f \quad \text{in } K \tag{39.a}
\]

\[
B\Psi_{bf} = 0 \quad \text{in } K \tag{39.b}
\]

\[
\Psi_{bf} = 0 \quad \text{on } \partial K. \tag{39.c}
\]

Since $\Phi_h$ is linear in each element $K$, for the sake of clarity, we set $\Phi'_h = a_K = a$, $S(\Phi_h) = \sqrt{1+a_h^2} = S_K = S$ and $h_K = h$. Now, problems (38) and (39) can be solved for each $\Psi_{li}$ and each $p_{li}$, we have:
Proposition 13. Assume that $\Phi \in \Lambda_\varepsilon$ and problem (P_2) admits a solution $(w, p)$ such that $w \in (H^1_b(I) \cap H^2(I))^3 \times (H^2(I))^2$ and $p \in (H^2(I))^2$ then problem (39) admits the solution $\Psi_{bf} = (\beta_{bf}, \gamma_{bf}, \theta_{bf}, \eta_{bf})$ and $p_f = (p_{f1}, p_{f2})$ such that:

$$
\begin{align*}
\beta_{bf} (\xi) &= -\frac{a (1 + a^2)}{6 \varepsilon^2} \left[ \frac{\xi^4}{4} - \frac{\xi^2}{2} h^2 + \frac{1}{4} h \xi^2 (3h - 2\xi) \right] - \frac{a^2}{2} + \frac{a}{2} h \xi \\
\gamma_{bf} (\xi) &= \frac{a^2}{2} (h - \xi) + \frac{a^2}{24 \varepsilon^2} \xi^2 (h - \xi)^2 \\
\theta_{bf} (\xi) &= -\frac{(1 + a^2)}{2 \varepsilon^2} \left[ \frac{1}{3} \xi (\xi^2 - h^2) + \frac{1}{2} h^2 \xi (h - \xi) \right] \\
\eta_{bf} (\xi) &= a \left( \frac{h}{2} - \xi \right), \quad \xi \in [0, h]
\end{align*}
$$

(40.a)

Proof. $\Psi_{bf}^i = (\beta_{bf}^i, \gamma_{bf}^i, \theta_{bf}^i, \eta_{bf}^i); \Psi_{bf} = (\beta_{bf}, \gamma_{bf}, \theta_{bf}, \eta_{bf}); p_f = (p_{f1}, p_{f2}); p_i = (p_{i1}, p_{i2})$.

Now, we write (with the same coefficients $C_{i, K}$):

$$
\begin{align*}
w_{kl} &= \Sigma_{i=1}^{n_K} C_{i, K} \Psi_{ti} \quad \text{and} \quad w_{bK} = \Sigma_{i=1}^{n_K} C_{i, K} \Psi_{b}^i + \Psi_{bf}.
\end{align*}
$$

Hence, equations (39) can be written as:

$$
\begin{align*}
&\begin{cases}
(a) & p_{f1} = 0 \\
(b) & p_{f2} = -\varepsilon S(\Phi_h) \\
(c) & -\varepsilon^3 \frac{\theta_{bf}}{S(\Phi_h)} = p_{f1} \Phi_{h}^t - p_{f2} \\
(d) & \varepsilon S(\Phi_h) \eta_{bf} = p_{f1} + \Phi_{h}^t p_{f2} \\
(e) & \beta_{bf} = \theta_{bf} \Phi_{h}^t + \eta_{bf} \\
(f) & \gamma_{bf} = \Phi_{h}^t \eta_{bf} - \theta_{bf}.
\end{cases}
\end{align*}
$$

(41)

In (41), from equations (b) and (c) we get, respectively, after integrating once with respect to the local variable $\xi = x - x_i \in [0, h]$,

$$
\begin{align*}
p_{f2} (\xi) &= -\varepsilon S \xi + C_1 \\
\theta_{bf} (\xi) &= -\frac{S}{\varepsilon^3} (p_{f1} a + \varepsilon S \xi - C_1).
\end{align*}
$$

(42)

Integrating twice with respect to $\xi$ and using the conditions $\theta_{bf} (0) = \theta_{bf} (h) = 0$ yields

$$
\theta_{bf} (\xi) = -\frac{S^2}{6 \varepsilon^2} \xi (\xi^2 - h^2) + \frac{S (C_1 - p_{f1} a)}{2 \varepsilon^3} \xi (\xi - h).
$$

(43)

Using from (41) equation (d) we obtain for $\eta_{bf}$:

$$
\eta_{bf} = \frac{1}{\varepsilon S} (p_{f1} + ap_{f2}).
$$

Hence from (42), we get:

$$
\eta_{bf} (\xi) = \frac{1}{\varepsilon S} (p_{f1} + aC_1 - a\varepsilon S \xi).
$$

(44)
Similarly, we use from (41) equations \((e)\) and \((f)\), to have:

\[
\beta_{bf}(\xi) = a \int_0^\xi \theta_{bf}(t) \, dt + \int_0^\xi \eta_{bf}(t) \, dt.
\]

Reporting expressions of \(\theta_{bf}\) and \(\eta_{bf}\) yields, with \(d = S(C_1 - p_{f1}a)/\varepsilon^3\) and \(f = -S^2/\varepsilon^2\):

\[
\beta_{bf}(\xi) = \frac{1}{6}a \left( \frac{\xi^4}{4} - \frac{\xi^2}{2} h^2 \right) - a \frac{d}{12} \xi^2 (3h - 2\xi) + \frac{1}{\varepsilon S} (p_{f1} + aC_1) \xi - a \frac{\xi^2}{2} \cdot (45)
\]

Now, using the condition \(\beta_{bf}(h) = 0\) and replacing \(f\) by its expression, we get with \(\alpha = h/\varepsilon\):

\[
C_1 = \frac{S^2 h^2 \alpha^2 + aSp_{f1} \alpha^3 - 6h^2}{S\alpha^3 - \frac{12}{S} \alpha} + \frac{12 p_{f1} \alpha}{a (S\alpha^3 - \frac{12}{S} \alpha)} . (46)
\]

Otherwise, using from (41) the equation \((f)\) and integrating once with respect to \(\xi\) yields

\[
\gamma_{bf}(\xi) = a \int_0^\xi \eta_{bf}(t) \, dt + \int_0^\xi \theta_{bf}(t) \, dt.
\]

So, substituting with the \(\eta_{bf}\) and \(\theta_{bf}\) expressions we get:

\[
\gamma_{bf}(\xi) = a \int_0^\xi \frac{f}{\varepsilon^3} (p_{f1} + ac_1) \xi - a \frac{\xi^2}{2} + \frac{f}{\varepsilon^3} \left( \frac{\xi^2}{2} h^2 - \frac{\xi^4}{4} \right) + \frac{S (C_1 - p_{f1}a)}{12\varepsilon^3} \xi^2 (3h - 2\xi) . (47)
\]

Hence, using (46) and (47) we obtain after brief calculation

\[
C_1 = \frac{\sqrt{1 + a^2}}{2} \frac{h\varepsilon}{\varepsilon} ; \quad p_{f1} = 0 . (48)
\]

Now, recalling (48) and reporting in (43) and (44) we obtain:

\[
\theta_{bf}(\xi) = -\frac{(1 + a^2)}{2\varepsilon^2} \left[ \frac{1}{3} \xi (\xi^2 - h^2) + \frac{1}{2} h^2 \xi (h - \xi) \right] . (50)
\]

and

\[
\begin{cases}
\eta_{bf}(\xi) = a\left(\frac{h}{2} - \xi\right) , \quad \xi \in [0, h[ \\
\eta_{bf}(0) = \eta_{bf}(h) = 0 .
\end{cases} (51)
\]

Similarly, replacing in (45) and (47) \(C_1\) and \(p_{f1}\) by their expressions, we get

\[
\beta_{bf}(\xi) = -\frac{a(1 + a^2)}{24\varepsilon^2} \xi^2 (\xi - h)^2 + \frac{a}{2} \xi (h - \xi) \cdot (52)
\]

and

\[
\gamma_{bf}(\xi) = \frac{a^2}{2} \xi (h - \xi) + \frac{1 + a^2}{24\varepsilon^2} \xi^2 (h - \xi)^2 . (53)
\]
Now, it remains to determine the local basis elements \( \Psi^i_b \) and \( p^i_b \). Let us, for the sake of clarity, introduce the quantities:

\[
\begin{align*}
m_1^i &= \frac{12 (a - 1)}{S^3} \varepsilon^3 - \frac{6 \varepsilon^3}{S h^2} - \frac{6}{S} \left( \frac{4}{a} + h \right) \frac{\varepsilon^3}{h^2} \\
m_2^i &= \frac{a + 1}{S} \frac{\varepsilon^3}{h^2} - \frac{6}{S} \frac{\varepsilon^3}{h^2} \\
m_1^b &= \frac{a + 1}{S} \frac{\varepsilon^3}{h^2} - \frac{6}{S} \frac{\varepsilon^3}{h^2} \\
m_2^b &= \frac{S}{h} \frac{\varepsilon^3}{h^2}
\end{align*}
\]

With the notation above, the following holds:

\[ (a) \quad \begin{align*}
\beta^i_b (\xi) &= -\frac{aS}{6 \varepsilon^3} m_1^3 \xi^3 + \left( \frac{aSm_1^1 h}{4 \varepsilon^3} + \frac{a}{2h} \right) \xi + \left( \frac{m_2^2}{\varepsilon S} - \frac{1}{h} \right) \xi \\
\gamma^i_b (\xi) &= \frac{S}{6 \varepsilon^3} m_1^3 \xi^3 - \left( \frac{Sm_1^1 h}{4 \varepsilon^3} + \frac{1}{2h} \right) \xi + \left( \frac{am_1^1}{\varepsilon S} - \frac{1}{h} \right) \xi \\
\theta^i_b (\xi) &= \frac{Sm_1^1}{2\varepsilon^2} \xi (h - \xi) \\
\eta^i_b (\xi) &= -\frac{\xi}{h} + \frac{m_1^1}{\varepsilon S} K
\end{align*} \]

\[ (b) \quad \begin{align*}
p^{i1}_b (\xi) &= -\frac{\xi}{h} + \frac{a + 1}{S^3} \frac{\varepsilon^3}{h} - \frac{6a \varepsilon^3}{S h^2} + \frac{12a(a - 1) \varepsilon^3}{S^3 h^2} \\
p^{i2}_b (\xi) &= -\frac{\xi}{h} - \frac{(a + 1) a \varepsilon}{S h^2} + \frac{6 \varepsilon^3}{S^3 h^2} + \frac{12(a - 1) \varepsilon^3}{S^3 h^2}
\end{align*} \]

and

\[ (a) \quad \begin{align*}
\beta^2_b (\xi) &= \left\{ -\frac{aS}{6 \varepsilon^3} m_2^3 \xi^3 + \left( \frac{aSm_1^1 h}{4 \varepsilon^3} - \frac{a}{2h} \right) \xi + \left( \frac{m_2^2}{\varepsilon S} + \frac{1}{h} + a \right) \xi \\
\gamma^2_b (\xi) &= \left\{ \frac{S}{6 \varepsilon^3} m_1^3 \xi^3 - \left( \frac{Sm_1^1 h}{4 \varepsilon^3} - \frac{1}{2h} \right) \xi + \left( \frac{am_1^1}{\varepsilon S} + \frac{1}{h} - 1 \right) \xi \\
\theta^2_b (\xi) &= \frac{Sm_1^1}{2\varepsilon^2} \xi (h - \xi) \\
\eta^2_b (\xi) &= -1 + \frac{\xi}{h} + \frac{m_2^2}{\varepsilon S} K
\end{align*} \]

\[ (b) \quad \begin{align*}
p^{21}_b (\xi) &= \frac{\xi}{h} - 1 - \frac{6}{S^3} (4 + ah) \frac{\varepsilon^3}{h^3} - \frac{1}{S h} \\
p^{22}_b (\xi) &= \frac{\xi}{h} - 1 - \frac{6}{S^3} (4 + ah) \frac{\varepsilon^3}{h^3} - \frac{a \varepsilon}{S h}
\end{align*} \]
Proof. Denote first, for $i = 1, n_K$, $\Psi^i = (\beta^i_1, \gamma^i_1, \theta^i_1, \eta^i_1)$ and let us ignore the subscript $i$ in the proof. Using in (38) equations (a) and (b), we get for $(w_i, p_i) \in V_i \times \Sigma_i$:

\[
\begin{align*}
(a) & \quad p_{b,1} = -p_{l,1} \\
(b) & \quad p_{b,2} = -p_{l,2} \\
(c) & \quad -\varepsilon^3 \frac{\theta^p_b}{S_K} = -\varepsilon^3 \frac{\theta^l_1}{S} + a (p_{l,1} + p_{b,1}) - p_{l,2} - p_{b,2} \\
(d) & \quad -\varepsilon S \eta_b = -\varepsilon S \eta_l + p_{l,1} + p_{b,1} + a (p_{l,2} + p_{b,2}) \\
(e) & \quad \beta^p_b = a (\theta^p_b + \theta^l_1) + (\eta^p_b + \eta^l_1) - \beta^l_1 \\
(f) & \quad \gamma^p_b = a (\eta^p_b + \eta^l_1) - (\theta^p_b + \theta^l_1) - \gamma^l_1.
\end{align*}
\]

Hence, from equations (a) and (b) yields, with $M_1$ and $M_2$ generic constants:

\[p_{b,1} = -p_{l,1} + M_1; \quad p_{b,2} = -p_{l,2} + M_2.\]

Now, equation (d) gives:

\[\eta_b = -\eta_l + \frac{1}{\varepsilon S} [M_1 + a M_2].\]

Since $\theta_l$ is linear in $K$, we have $\theta^l_1 = 0$ and then from (c) yields:

\[\theta^p_b = -\frac{S}{\varepsilon^3} (a M_1 - M_2).\]

As the elements $\theta_l, \beta_l, \gamma_l, p_{l,1}$ and $p_{l,2}$ are linearly in $K$, one has:

\[
\begin{align*}
(i) & \quad \theta_l = \theta^l_1 = \beta_l = \beta^l_1 = \gamma_l = \gamma^l_1 = p_{l,1} = p_{l,2} = \frac{\xi}{h} \\
(ii) & \quad \theta_l = \theta^l_2 = \beta_l = \beta^l_2 = \gamma_l = \gamma^l_2 = p_{l,1} = p_{l,2} = 1 - \frac{\xi}{h}.
\end{align*}
\]

In the first case we get:

\[p_{b,1}^1 = -\frac{\xi}{h} + M_1; \quad p_{b,2}^1 = -\frac{\xi}{h} + M_2.\]

Setting: $m_1^1 = a M_1^1 - M_2$ and $m_2^1 = M_1^1 + a M_2^1$ yields:

\[\eta^p_b (\xi) = -\frac{\xi}{h} + \frac{m_2^1}{\varepsilon S}.\]

Integrating twice with respect to $\xi$ and recalling $\theta_b (0) = \theta_b (h) = 0$, we obtain

\[\theta^l_b (\xi) = \frac{S m_1^1}{2 \varepsilon S} \xi (h - \xi).\]

Otherwise, using from (57) equation (e) and integrating, we get:

\[\beta_b (\xi) = a \int_0^\xi (\theta_b + \theta_l) (t) dt + \int_0^\xi (\eta_b + \eta_l) (t) dt - \beta_l (\xi) + \beta_l (0)\]
so according to (60) and (61)

\[
\beta^1_b (\xi) = -\frac{aS}{6\varepsilon_0^2 m^1_1} \xi^3 - \left( \frac{aS m^1_1 h}{4\varepsilon^3} + \frac{a}{2h} \right) \xi^2 + \left( \frac{m^2_1}{\varepsilon S} - \frac{1}{h} \right) \xi. \tag{62}
\]

Similarly, using equation (f) and integrating with respect to \( \xi \) we obtain:

\[
\gamma^1_b (\xi) = a \int_0^\xi (\eta_b + \eta_l) (t) \, dt - \int_0^\xi (\theta_b + \theta_l) (t) \, dt - \gamma_l (\xi) + \gamma_l (0) .
\]

Hence, from (60) and (61):

\[
\gamma^1_b (\xi) = \frac{S}{6\varepsilon_0^2} m^1_1 \xi^3 - \left( \frac{S m^1_1 h}{4\varepsilon^3} + \frac{1}{2h} \right) \xi^2 + \left( \frac{a m^2_1}{\varepsilon S} - \frac{1}{h} \right) \xi. \tag{63}
\]

In other words:

\[
\gamma^1_b (\xi) = -\frac{\beta^1_b (\xi)}{a} + \left( -\frac{a + 1}{ah} + \frac{a^2 + 1}{a\varepsilon m^2_1} \right) \xi. \tag{64}
\]

Finally it remains to determine the constants \( m^1_1 \) and \( m^1_2 \). This can be done by the use of the conditions \( \beta^1_b (h) = \gamma^1_b (h) = 0 \). According to (63) we have:

\[
m^1_2 = \frac{a + 1}{S} \frac{\varepsilon}{h}. \tag{65}
\]

On the other hand, using the expression of \( \beta^1_b \), we get after brief calculation

\[
\frac{aS}{12} m^1_1 h^2 + \frac{1}{\varepsilon S} m^1_2 = \frac{1}{h} - \frac{a}{2}.
\]

Substituting \( m^1_2 \) by its expression we obtain:

\[
m^1_2 = \frac{12 (a - 1) \varepsilon^3}{S h^3} - \frac{6 \varepsilon^3}{S h^2} . \tag{66}
\]

Back to \( M^1_1 \) and \( M^1_2 \) we get:

\[
\begin{cases}
M^1_1 = \frac{a + 1}{S^3} - \frac{6a}{S^3 h^2} + \frac{12a(a - 1) \varepsilon^3}{S h^3}
\end{cases}
\]

\[
M^1_2 = -\frac{(a + 1) a \varepsilon}{S^3} - \frac{6 \varepsilon^3}{S^3 h^2} + \frac{12(a - 1) \varepsilon^3}{S h^3} . \tag{67}
\]

Finally, we obtain the exact expressions of bubble basis functions \( p^1_b = (p^1_{b1}, p^1_{b2}) \) and \( \Psi^1_b = (\beta^1_b, \gamma^1_b, \beta^1_c, \gamma^1_c) \) by substituting in (60) to (63) the constants \( m^1_1, m^1_2, M^1_1 \) and \( M^1_2 \) by their values respectively. Similarly working as in case (i) we have for case (ii):

\[
\begin{cases}
\eta^2_b (\xi) = -\frac{1}{h} + \frac{m^2_2}{\varepsilon S}
\end{cases}
\]

\[
\theta^2_b (\xi) = \frac{S m^1_2}{2 \varepsilon^3} (\xi (h - \xi)). \tag{68}
\]
For the expressions of $\beta_0^2$ and $\gamma_0^2$ we get (respectively):

$$\beta_0^2 (\xi) = - \frac{aS}{6\varepsilon^3} m_1^2 \xi^3 + \left( \frac{a Sm_2^2 h}{4\varepsilon^3} - \frac{a}{2h} \right) \xi^2 + \left( \frac{m_2^2}{\varepsilon S} + \frac{1}{h} + a \right) \xi$$  \hspace{1cm} (69)$$

$$\gamma_0^2 (\xi) = \frac{S}{6\varepsilon^3} m_1^2 \xi^3 - \left( \frac{Sm_2^2 h}{4\varepsilon^3} - \frac{1}{2h} \right) \xi^2 + \left( \frac{am_2^2}{\varepsilon S} + \frac{1}{h} - 1 \right) \xi$$  \hspace{1cm} (70)$$

in other words, we have:

$$\gamma_0^2 (\xi) = - \frac{\beta_0^2 (\xi)}{a} + \left( \frac{a + 1}{h} + \frac{a + 1}{aS\varepsilon m_2^2} \right) \xi. \hspace{1cm} (71)$$

We then determine the constants $m_1^2$ and $m_2^2$ by using the conditions $\beta_0^2 (h) = \gamma_0^2 (h) = 0$. Hence, according to (69) one has

$$m_2^2 = \frac{S}{h}. \hspace{1cm} (72)$$

Using the expression of $\beta_0^2 (\xi)$ given by (69) and recalling $\beta_0^2 (h) = 0$ yields:

$$a S m_2^2 h^2 + \frac{1}{\varepsilon S} m_2^2 = - \frac{1}{h} \cdot \frac{a}{2}. \hspace{1cm} (73)$$

Replacing $m_2^2$ by its value gives:

$$m_1^2 = - \frac{6}{S} \left( \frac{4}{a} + h \right) \frac{\varepsilon^3}{h^3}. \hspace{1cm} (74)$$

Consequently:

$$M_1^2 = - \frac{6}{S} \left( 4 + ah \right) \frac{\varepsilon^3}{h^3} + \frac{1}{5\varepsilon} h; \hspace{1cm} M_2^2 = - \frac{6}{S} \left( \frac{4}{a} + h \right) \frac{\varepsilon^3}{h^3} - \frac{a}{5h}. \hspace{1cm} (75)$$

Finally, we obtain the expressions of $p_0^2 = (p_0^1, p_0^2)$ and $\Psi_0^2 = (\beta_0^2, \gamma_0^2, \theta_0^2, \eta_0^2)$ by replacing the constants $m_1^2, m_2^2, M_1^2$ and $M_2^2$ by their values respectively.

**Application to the perturbed problem.** Consider the problem $(P_h)$, if we select $\tau_h = \tau_1$ in the first equation and $q_h = q_1$ in the second one, we get:

$$\begin{align*}
a_h (w_1, \tau_1) + b_h (\tau_1, p_1) + a_h (w_2, \tau_1) + b_h (\tau_1, p_2) &= l_h (\tau_1) \\
b_h (w_1, q_1) + b_h (w_2, q_1) &= 0.
\end{align*} \hspace{1cm} (75)$$
Where:

\[
\begin{align*}
    a_h(w_l, \tau_l) &= \varepsilon \Sigma_K S_K \int_K \eta \theta_l \, dx + \frac{\varepsilon}{12} \sum_K \frac{1}{S_K} \int_K \theta \theta' \, dx \\
    b_h(\tau_l, p_l) &= \Sigma_K \left\{ \left( \beta'_l - a_k \theta_l - \eta_l, p_l \right)_K + \left( \gamma'_l + \theta_l - a_k \eta_l, p_{l2} \right)_K \right\} \\
    b_h(\tau_l, p_b) &= \Sigma_K \left\{ \left( \beta'_l - a_k \theta_l - \eta_l, p_{l1} \right)_K + \left( \gamma'_l + \theta_l - a_k \eta_l, p_{l2} \right)_K \right\} \\
    a_h(w_b, \tau_l) &= \varepsilon \Sigma_K S_K \int_K \eta \theta_l \, dx \\
    b_h(w_b, q_l) &= \Sigma_K \left\{ (\beta'_b - a_k \theta_b - \eta_b, q_l)_K + (\gamma'_b + \theta_b - a_k \eta_b, q_{l2})_K \right\}.
\end{align*}
\]

Where, integrating by parts we have used the equality:

\[
\sum_K \frac{1}{S_K} \int_K \theta \theta' \, dx = \sum_K \frac{1}{S_K} \left[ \left( \theta_l, \theta'_l \right)_K - \left( \theta_l, \theta'_{lK} \right)_K \right] = 0.
\]

Now, writing:

\[
\begin{align*}
    w_b &= \sum_{j=1}^{n_K} c_{j,K} \left( \beta'_b, \gamma'_b, \theta'_b, \eta'_b \right) + \left( \beta_{bf}, \gamma_{bf}, \theta_{bf}, \eta_{bf} \right); \\
    \left( p_{b1}, p_{b2} \right) &= \sum_{j=1}^{n_K} d_{j,K} \left( p_{b1}^{j}, p_{b2}^{j} \right) + \left( p_{f1}, p_{f2} \right).
\end{align*}
\]

If we substitute in (72) the expressions of \( \beta'_b, \gamma'_b, \theta'_b, \eta'_b \) and in (75) those of \( p_{b1}^{j}, p_{b2}^{j} \) and \( p_{f1}, p_{f2} \), we obtain a linear system with coefficients \( c_{j,K}, d_{j,K} \) as unknowns.

### 4.1. Numerical experiments

Each of the standard Galerkin (\( G \)) and the Galerkin with bubbles (\( G+BF \)) leads to the matricial formulation:

\[
(S) \left\{ \begin{array}{l}
A \mathbf{X} + B \mathbf{P} = \mathbf{F} \\
B \mathbf{X} = \mathbf{G}
\end{array} \right.
\]

where \( \mathbf{X} \) and \( \mathbf{P} \) are vectors which components are the nodal parameters of displacement and Lagrange multipliers respectively, \( A \) and \( B \) are the matrices corresponding to the bilinear forms \( a(.,.) \) and \( b(.,.) \), \( \mathbf{F} \) and \( \mathbf{G} \) the second members. If \( A_K \) and \( B_K \) denote the element matrices it will be interesting to see that, with piecewise linear elements, \( A_K \) is bloc diagonal where the diagonal terms are the matrices \( A_\beta = A_{11}, A_\gamma = A_{22}, A_\theta = A_{33} \) and \( A_\eta = A_{44} \) associated to the components displacement vector \( \beta, \gamma, \theta \) and \( \eta \) respectively. Note that in the case of standard Galerkin (\( G \)), \( A_\beta = A_\gamma = 0 \) and:

\[
\begin{align*}
    A_\beta &= \frac{1}{12 (a^2 + 1)^2} \frac{\varepsilon^2}{h} \begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix}, \quad A_\gamma = \frac{(a^2 + 1)^2}{6} h \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}
\end{align*}
\]
$B$ is of the form, with $(B_{21} = B_{12} = 0, B_{13} = B_{24} = aB_{14})$ and with $B_{11} = B_{22} = \frac{1}{2} \begin{pmatrix} -1 & 1 \\ -1 & 1 \end{pmatrix}$;

\[ B_{14} = -B_{23} = -\frac{h}{6} \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix} \]

\[ B = \begin{bmatrix} B_{11} & B_{12} & B_{13} & B_{14} \\ B_{21} & B_{22} & B_{23} & B_{24} \end{bmatrix} \]

In the Galerkin with bubbles method the matrix $A$ becomes $A + b(A)$, the the diagonal terms are now:

\[ A_{\beta} + b(A_{\beta}), A_{\gamma} + b(A_{\gamma}), A_{\theta} + b(A_{\theta}) \text{ and } A_{\eta} + b(A_{\eta}) \]

where $b(A_{\beta}) = b(A_{\gamma}) = b(A_{\theta}) = 0$ and $b(A_{\eta}) = \left( \frac{1-h}{3} - \frac{h}{3} + \frac{a+1}{2} \right)$ and similarly the matrix $B$ becomes $B + b(B)$ with $b(B_{12}) = b(B_{21}) = 0, b(B_{14}) = -\frac{b(B_{12})}{a}, b(B_{24}) = -ab(B_{23})$ and:

\[ b(B_{11}) = \left( \frac{1}{2} - M_1^1 \right) \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}; \quad b(B_{13}) = \left( ah \left( \frac{1}{3} - M_2^1 \right) \right) \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix} \]

\[ b(B_{14}) = \left( -\frac{1}{2} + M_2^3 \right) \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}; \quad b(B_{23}) = \left( -\frac{h}{3} + M_2^0 \right) \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix} \]

To illustrate the results above, we test the methods on an arch of shape $\Phi(x) = x^2 - x$ subjected to uniform unit load.

4.2. Conclusion

A standard Galerkin mixed method (G) and the Galerkin method enriched with residual-free bubbles (RFB) for equal order linear elements are considered to approximate the displacement of a general arch problem. We show that the (RFB) method consists in fact of the standard Galerkin formulation plus mesh dependent terms. The bubble functions, assumed to satisfy the governing differential equations in each element interior of a regular grid, are determined exactly. Numerical experiments are carried out for an arch with a given smooth shape which supports a uniform unit load. The results are presented for the values $\varepsilon = 1, \varepsilon = 10^{-1}$ and $\varepsilon = 10^{-2}$ of the thickness. The graphics show that the approximated rotation of the normal vector by the Galerkin method has a similar behaviour to exact one (Figs. 1 and 2). On the other hand, the approached membrane energy with classical Galerkin method presents a pathological behaviour which consists of a boundary layer phenomena observed for $\varepsilon \leq 10^{-1}$. Experiments show that an improvement is brought to the behaviour of the membrane energy component by the use of the (RFB) method (Figs. 3 and 4).
