Some arithmetical results on semi-simple Lie algebras

<http://www.numdam.org/item?id=PMIHES_1966__30__115_0>
SOME ARITHMETICAL RESULTS
ON SEMI-SIMPLE LIE ALGEBRAS

T. A. SPRINGER

Introduction.

The present paper had its origin in an attempt to prove the existence of regular unipotent elements in a semi-simple linear algebraic group $G$ over an algebraically closed field $k$ (of arbitrary characteristic $p$). The attempt was not completely successful, it turned out to give results only under some (rather mild) restrictions on $p$. Our method, which is given in § 4 of this paper, makes an essential use of the explicit formulas for the structure of the unipotent part $U$ of a Borel subgroup $B$ of $G$, which are due to Chevalley ([9]). The application of these formulas to our problem leads one to investigate an arithmetical problem about semi-simple Lie algebras. This is the following problem. Let $\mathfrak{g}$ be a Lie algebra over the ring of integers $\mathbb{Z}$, associated with a complex semi-simple Lie algebra. Let $\{e_i\}$ be the set of "root vectors" of $\mathfrak{g}$, let $n = \sum e_i$, where the summation is over a set of simple roots. Determine the elementary divisors of the endomorphism $\text{ad}(a)$ of $\mathfrak{g}$.

This arithmetical problem is dealt with in § 2 of the paper (after some introductory material in § 0 and § 1). The results for the case that the root system of $\mathfrak{g}$ is simple, are given in (2.6). Their proofs rely heavily on the explicit knowledge of the simple root systems. We need, for example, for the exceptional simple types $E_6$, $E_7$, $E_8$, $F_4$, tables giving the positive roots when expressed in the simple ones (these tables are given in an appendix). We also need some properties of the integral structure constants $N_{a,b}$ of a semi-simple Lie algebra. From (2.6) we derive various characterizations of the "bad" primes for $\mathfrak{g}$, i.e. (in the simple case) those which divide the coefficients of the highest root of $\mathfrak{g}$. The results are given in (2.11). It would be interesting to have a priori proofs of these characterizations, the proofs of the present paper are by "checking cases". In § 3 we make some remarks about the torsion of compact, semi-simple, simply connected Lie groups. The results are obtained by comparing those of § 2 with results which are proved in topology.

§ 4 contains results about regular unipotent elements in semi-simple algebraic groups over algebraically closed ground fields. Their existence has been proved
meanwhile by Steinberg (in [17]), without restrictions on $p$, by a different method. Our method leads to some further results about the structure of the centralizer of a regular unipotent element (see (4.11) and (4.12)).

Finally in § 5, the discussion of § 4 is partly carried over to the corresponding problem for the Lie algebra of a semi-simple algebraic group.

0. Preliminaries.

(0.1) Let $E$ and $F$ be two free abelian groups of finite rank; let $t$ be a homomorphism of $E$ into $F$. We define, as usual, the rank of $t$ to be the rank of $t(E)$. We call elementary divisors of $t$ the elementary divisors of the module $F/t(E)$ ([7], Chap. VII, § 4, n° 7). These are the prime powers which occur as orders of direct summands in the decomposition of the torsion-group $\text{Tors}(F/t(E))$ as a direct sum of indecomposable groups. An elementary divisor $p^n$ has a certain multiplicity, which is the number of indecomposable summands of order $p^n$.

We say that $t$ has no elementary divisors if $F/t(E)$ is torsion free (in particular, if $t$ is surjective).

Choosing bases in $E$ and $F$, we can describe $t$ by an integral matrix $M$. Then the elementary divisors of $M$ are by definition those of $t$. It is known that the elementary divisors of the transposed matrix $M^t$ and their multiplicities are the same as those of $M$.

(0.2) With the same notation, let $E_1$ be a submodule of $E$. We call $E_1$ primitive if $E/E_1$ is torsion free or, equivalently, if $E_1$ is a direct summand. $E_1$ being primitive, let $t_1$ be the homomorphism $E/E_1 \rightarrow F/t(E_1)$ induced by $t$.

We then have the following simple lemma, the proof of which is left to the reader.

(0.3) Lemma. — If $t(E_1)$ is primitive in $F$, then the elementary divisors of $t$ and their multiplicities are the same as those of $t_1$.

1. Results about semi-simple Lie algebras.

In this section we recall a number of results about semi-simple Lie algebras and their root systems, which we have to use. References are [9], [14] (exposés 14, 19).

(1.1) We start with a root system $R$ in an $l$-dimensional vector space $V$ over $\mathbb{R}$, with an Euclidean metric (given by a symmetric bilinear form $(x,y)$). This is a finite set of nonzero vectors, called roots, with the following properties:

a) $R$ contains a basis of $V$;

b) if $r \in R$, then $-r \in R$, no other multiples of $r$ lie in $R$;

c) if $r \in R$, then $T_r(R) = R$, where $T_r$ is the reflection in $V$ defined by $T_r(x) = x - 2(r, r)^{-1}(x, r)r$;

d) for $r,s \in R$, $e_{rs} = 2(r,s)^{-1}(r,s)$ is an integer.

$l = \dim V$ is called the rank of $R$. The root system $R$ is called simple if it cannot be decomposed into two mutually orthogonal subsets. The simple root systems $R$ can
be classified. The classification gives the simple types \( A_l \) \( (l \geq 1) \), \( B_l \) \( (l \geq 2) \), \( C_l \) \( (l \geq 3) \), \( D_l \) \( (l \geq 4) \), \( E_6, E_7, E_8 \), \( F_4, G_2 \). We do not enter into the classification here; in \( \S \) 2 we shall have to use extensively the explicit description of the simple root systems.

(1.2) In a simple system \( R \) one defines the \textit{length} of a root \( r \) as the ratio \( (r, r)(r_0, r_0)^{-1} \), where \( r_0 \) is a fixed root in \( R \) such that \( (r_0, r_0) \) is smallest. The length of a root is 1 in the simple types \( A_l, D_l, E_6, E_7, E_8 \), 1 or 2 in the types \( B_l, C_l, F_4 \), 1 or 3 in the type \( G_2 \). If all roots have length 1, then for \( r \neq s \) the integers \( e_{rs} \) are 0 or \( \pm 1 \).

(1.3) There exist sets of \textit{simple} roots \( S \) in \( R \). These are subsets \( S \) of \( R \) consisting of \( l \) roots, whose characteristic property is the following one: any \( r \in R \) is a linear combination

\[
\sum_{s \in S} n_s s
\]

with integral coefficients \( n_s \), all having the same sign. \( h(r) = \sum_{s \in S} n_s \) is then called the \textit{height} of \( r \). The root \( r \) is called \textit{positive} if \( h(r) > 0 \), \textit{negative} if \( h(r) < 0 \) (all this depends on \( S \)). If \( S \) and \( S' \) are two sets of simple roots, then there exists a unique element \( w \) of the \textit{Weyl group} \( W \) of \( R \), the group generated by the reflections \( T_s \) of \( r \), such that \( S' = w(S) \). The Weyl group \( W \) is also the group generated by the \( T_s \) \( (s \in S) \).

Let us recall too that, if \( R \) is simple, there is exactly one root \( r \) with maximal height; we call it the \textit{highest root}.

(1.4) Let \( \Gamma \) be the lattice in \( V \) spanned by the vectors \( 2(r, r)^{-1}r \) \( (r \in R) \). Let \( \Gamma' \) be the lattice in \( V \) formed by the \( x \in V \) such that

\[
(x, r) \in \mathbb{Z}
\]

for all \( r \in R \).

By (1.1) \( d \) we have \( \Gamma' \supset \Gamma \). The quotient \( \Gamma'/\Gamma \) is a finite abelian group, the \textit{fundamental group} of \( R \). It is isomorphic to \( \mathbb{Z}/(l+1)\mathbb{Z} \) for type \( A_l \), to \( \mathbb{Z}/2\mathbb{Z} \) for types \( B_l \), \( C_l \) and \( E_l \), to \( (\mathbb{Z}/2\mathbb{Z})^2 \) for type \( D_l \) \( (l \text{ even}) \), to \( \mathbb{Z}/4\mathbb{Z} \) for type \( D_l \) \( (l \text{ odd}) \), to \( \mathbb{Z}/3\mathbb{Z} \) for type \( E_8 \), and is reduced to the identity in the other cases of a simple root system.

(1.5) Take any lattice \( \Delta \) in \( V \) such that \( \Gamma \subset \Delta \subset \Gamma' \) (hence \( (x, r) \) takes integral values if \( x \in \Delta \)).

We now define a Lie algebra \( g \) over \( \mathbb{Z} \) (\(^1\)). Put

\[
g = \Delta + \sum_{r \in R} \mathbb{Z} e_r,
\]

where the Lie algebra product is as follows:

\[
\begin{align*}
[e_r, e_s] &= (r, s)e_r + (r, s) e_s, \\
[e_r, e_{-r}] &= 2(r, r)^{-1} r,
\end{align*}
\]

\(
(1)
\)

\(^1\) The Lie algebra \( g \) over \( \mathbb{Z} \) which we define here is somewhat more general than that discussed in \([9]\), p. 32 where only the case \( \Delta = \Gamma \) is considered. We also have identified here \( V \) with its dual, by means of the inner product.
Here the $N_{rs}$ are certain integers, 0 if $r+s \notin R$. They are discussed in Chevalley's fundamental paper [9]. Below we shall review the results which we shall need. We call the $N_{rs}$ the structure constants of $g$.

(1.6) Some comments on the structure constants must be made. In the first place, in order for (i) to define a Lie algebra, Jacobi's identity must hold. This gives that the structure constants have to satisfy the following relations

\[
\begin{align*}
N_{rs} &= -N_{sr}, \\
N_{r-r,s} &= N_{r,s} + N_{s,r}, \\
N_{r+s,t} &= N_{s+t,r} + N_{r,s+t} + N_{p,N_{r+s+t}} = 0
\end{align*}
\]  

(it being understood here that $N_{rs} = 0$ if $r$, $s$ or $r+s$ is not a root).

That complex structure constants $N_{rs}$ exist, is a nontrivial classical result, due to É. Cartan, proved usually by "checking cases". In Cartan's thesis ([8], Chap. V) one already finds explicit integral solutions of (2). More detailed results are given in [9].

We collect those which we need in lemmas.

(1.7) Lemma. — Suppose $r, s, r+s \in R$. The $i \in \mathbb{Z}$ such that $s+i r \in R$ form a closed interval $[p, q]$ in $\mathbb{Z}$ with $p, q \geq 0$.

a) For any solution of (2) we have $N_{rs} N_{r-s} = -(p+1)^2$;

b) There exists a solution of (2) such that for all $r, s, r+s \in R$ we have $N_{rs} = \pm (p+1)$, where $p$ is the integer defined above;

c) If $(N_{rs})$ and $(N'_{rs})$ are two solutions of (2) satisfying b), then there exists a function $\varepsilon : R \to \{1, -1\}$ with $\varepsilon(r) = \varepsilon(-r)$ such that $N_{rs} = \varepsilon(r) \varepsilon(s) \varepsilon(r+s) N_{rs}$.

For the proofs of these statements see [9], p. 22-23. In the next lemma $(N_{rs})$ is any solution of (2).

(1.8) Lemma. — Suppose that $r, s, r+s \in R$.

a) $N_{r-r,s} (N_{s,r+s})^{-1}$ is a negative rational number;

b) If $\pm r$, $\pm s$, $\pm (r+s)$ are the only linear combinations of $r$ and $s$ which are roots, then $N_{r-r,s} = -N_{s,r+s}$.

With the notations of (1.7) Jacobi's identity implies $N_{rs} N_{r-r,s} = q(p+1)$ (see [6], p. 22). A similar formula is true with $r$ and $s$ interchanged. Since $N_{rs} = -N_{sr}$, a) follows. Under the hypothesis of b) the right hand sides in these relations are 1, which proves the assertion of b).

(1.9) Lemma. — Suppose that all roots have the same length. Assume that a set $S$ of simple roots has been fixed. Then there exist structure constants $N_{rs}$ such that $N_{rs} = 0$ or 1 if $s$ is simple and $h(r) \geq 2$ (1).

Suppose that the following assertion has been proved: (*) there exist structure constants such that $N_{rs} = 0$ or 1 if $s$ is simple and $h(r) \geq i+1$.

---

(1) I owe this lemma to H. de Vries. It replaces a more complicated lemma and it led to some simplifications in the discussion of (2.9).
We shall show below that if \( i \geq 2 \), \((*)\) holds too with \( i + 1 \) replaced by \( i \). Since \((*)\) is obviously true for large \( i \), \((1.9)\) follows.

Since all roots have the same length, we may assume that \( (r, r) = 2 \) for all \( r \in R \). It is known then, that if \( r \) and \( r' \) are linearly independent roots, we have \( (r, r') = 0 \) or \( \pm 1 \) and moreover that \( (r, r') = -1 \) if and only if \( r + r' \) is a root.

Fix \( r \) with \( h(r) = i \) and assume that \( N_{rs} \neq 0 \) where \( s \) and \( t \) are simple and \( s \neq t \).

By our previous remarks we have \( (r, s) = (r, t) = -1 \). Now if \( (s, t) = 1 \), \( s - t \) would be a root, which is impossible. Hence \( (s, t) \leq 0 \). If \( (s, t) = -1 \), we would have \( (r + s, t) = -2 \), which is also impossible. So \( (s, t) = 0 \), and \( (r + s, t) = -1 \). Hence \( r + s + t \) is a root. Then Jacobi's identity implies that
\[
N_{r + s, t} = N_{r + s, t} = 1.
\]
By \((*)\) we have \( N_{r + s, t} = N_{r + s, t} = 1 \). It follows that \( N_{rs} = N_{s1} \). Changing the structure constants according to \((1.7)\) \( c \), with \( \varepsilon(r') = 1 \) if \( r' = \pm r \), we may assume that \( N_{rs} = 0 \) or \( i \) for our fixed root \( r \) with height \( i \) and for all simple \( s \). If \( i \geq 2 \), we can deal separately with each \( r \), proving that \((*)\) is true with \( i \) instead of \( i + 1 \).

**Remark.** — The same argument shows the following. Let \( S = S_1 \cup S_2 \), where \( S_i \) consists of orthogonal roots. Then structure constants exist which have, besides \((1.9)\), also the following property:
\[
N_{s + t} = N_{s + t} = 1 \quad \text{if} \quad s \in S_1, \quad t \in S_2.
\]

\((1.10)\) We now define on our Lie algebra \( g \) a grading as follows. Take a set \( S \) of simple roots, let \( h \) denote the height as in \((1.3)\). Define
\[
g^0 = \Delta, \quad g_t = \sum_{h(r) = t} \mathbb{Z} e_r \quad (i \neq 0).
\]
We put \( l_i = \text{rank } g^i \) (= number of roots \( r \) with height \( i \) if \( i \neq 0 \)). It is easily verified that
\[
[g^i, g^j] \subseteq g^{i+j},
\]
so that we have made \( g \) into a graded Lie algebra over \( \mathbb{Z} \).

The grading depends on the choice of the simple roots. However, if we take another set \( S' \) of simple roots, there exists \( w \in W \) such that \( w(S) = S' \). Moreover, by \((1.7)\) \( c \) we have
\[
N_{w(r), w(s)} = \varepsilon(r)\varepsilon(s)\varepsilon(r+s)N_{rs},
\]
where \( \varepsilon \) is a function \( R \to \{1, -1\} \). Define an endomorphism \( \Phi \) of \( g \) by
\[
\Phi(h) = w(h) \quad (h \in \Delta), \quad \Phi(e_r) = \varepsilon(r)e_{w(r)}.
\]
It is easily seen that \( \Phi \) is an automorphism of the Lie algebra \( g \). Let
\[
g = \sum (g^i)^j.
\]
be the grading defined (as above) by $S'$. Then

$$\Phi(g') = (g')',\]$$

This shows that the graded Lie algebra structure on $g$ is unique up to isomorphism.

(1.11) Fix a set $S$ of simple roots. Define then an element $n \in g$ by

$$n = \sum_{\alpha \in S} e_{\alpha}.$$ 

It is clear that $n$ is a nilpotent element of $g$, i.e. such that $\text{ad} \ n : x \mapsto [n, x]$ is a nilpotent endomorphism of $g$. We call $n$ a principal nilpotent element of $g$ (such elements have been investigated by Kostant ([12], [13]) for the case of semi-simple Lie algebras over the complex field).

One may prove by an argument like that used in (1.10) that if $n$ and $n'$ are two principal nilpotents, defined by sets $S$ and $S'$ of simple roots, we have $n' = \Phi(n)$ where $\Phi$ is an automorphism of $g$.

In the next section we shall investigate in detail the action of $\text{ad} \ n$ in $g$.

Remark. — Our definition of a principal nilpotent is unsatisfactory in that it depends on the choice of a particular basis in $g$. In Kostant's paper [12] cited above, intrinsic characterizations are given of principal nilpotent elements of a complex semi-simple Lie algebra. For instance, they are those nilpotent elements whose centralizer has least possible dimension. The author does not know similar characterizations for the algebras over $\mathbb{Z}$. Because it is not necessary for the purpose of this paper, we don't want to pursue this matter further here.

2. The action of a principal nilpotent element.

(2.1) In this section $g$ is a Lie algebra over $\mathbb{Z}$ of the type considered in § 1. The root system $R$ is assumed to be simple, the structure constants $N_{\alpha\beta}$ are assumed to have the properties of (1.7) b) and (1.9). A set $S$ of simple roots is fixed, the grading of $g$ is that defined by $S$. If $n$ denotes the principal nilpotent element, we define homomorphisms (of abelian groups)

$$t_i : g^i \rightarrow g^{i+1}$$

by

$$t_i(x) = [n, x].$$

It is the purpose of this section to investigate the elementary divisors of the $t_i$.

But first we want to recall a known result about the ranks of the $t_i$.

(2.2) Proposition. — $t_i$ is injective for $i \leq 0$, rank $t_i = t_{i+1} (= \text{rank } g^{i+1})$ for $i \geq 0$.

A proof of (2.2) is contained in [12]. For the convenience of the reader we indicate one here.

Consider the Lie algebra $g_\mathbb{Q} = g \otimes_{\mathbb{Z}} \mathbb{Q}$. We imbed $g$ in $g_\mathbb{Q}$ in the obvious way. We choose

$$a = \sum_{s \in S} (2(s, s)^{-1}) \otimes \xi_s.$$
that 
That such a choice is possible follows from the definitions (1) in (1.5) of the product
in \( g \): the \( \xi_r \) have to satisfy

\[
\sum_{r \in S} \xi_r \epsilon_r = 1 \quad (r \in S).
\]

(4) can be solved in rational numbers, for the Cartan-matrix \((\epsilon_r)_{r,s \in S}\) is nonsingular.
Moreover it follows from (4), that for all \( r \in \mathbb{R} \) we have

\[
[a, \epsilon_r] = h(r) \epsilon_r,
\]

where \( h \) denotes the height (defined in (1.3)).

Now let \( n \) be as above (identified with \( n \oplus 1 \in \mathfrak{g}_0 \)), put \( n' = \sum_{r \in S} \epsilon_r \otimes \xi_r \). Then

\[
[n, n'] = a, \quad [a, n] = n, \quad [a, n'] = -n'.
\]

\( a, n, n' \) span a three-dimensional simple subalgebra \( \mathfrak{s} \) of \( \mathfrak{g}_0 \). Moreover \( o \) is the only
element of \( \mathfrak{g}_0 \) annihilated by \( \text{ad} \, a \), \( \text{ad} \, n \), \( \text{ad} \, n' \). For such an element must lie in \( \mathfrak{g}_0^0 \) (by (5))
and there both \( \text{ad} \, n \) and \( \text{ad} \, n' \) act injectively, because of the non-singularity of the
Cartan-matrix. Also by (5), the eigenvalues of \( \text{ad} \, a \) are integral. It then follows from
the representation theory of \( \mathfrak{s} \) (see [11], p. 85) that there exist elements \( x_1, \ldots, x_6 \) in \( \mathfrak{g}_0 \)
and odd positive integers \( 2k_1 + 1, \ldots, 2k_6 + 1 \) with the following properties:

a) \( x_i \in \mathfrak{g}_0^{-k_i} \), \( (\text{ad} \, n)^{2k_i + 1} x_i = 0 \);

b) \( (\text{ad} \, n)^j x_i \) \( (1 \leq i \leq h, 0 \leq j \leq 2k_i) \) is a basis of \( \mathfrak{g}_0 \).

It now follows that \( (\text{ad} \, n)x = 0 \) implies that \( x \) is a linear combination of the
\( (\text{ad} \, n)^{2k_i} x_i \) \( (1 \leq i \leq h) \), which implies the first assertion of (2.2). The second one is
obtained by observing that from b) it follows that \( (\text{ad} \, n) \mathfrak{g}_0^i = \mathfrak{g}_0^{i+1} \) for \( i \geq 0 \). Moreover,
observing that rank \( \mathfrak{g}_0 = l \), we find that \( h = l \).

(2.3) Corollary. — a) If \( i < 0 \) we have \( l_i \leq l_{i+1} \), if \( i > 0 \) we have \( l_{i+1} \leq l_i \);

b) Let the positive integers \( (k_i)_{1 \leq i \leq h} \) be such that \( k_1 < k_2 < \ldots < k_h \) and that for \( i > 0 \)
we have \( l_i > l_{i+1} \) if and only if \( i = k_j \) for some \( j \). Then \( h = l \); moreover for \( i < 0 \) we have
\( l_i < l_{i+1} \) if and only if \( i = -k_j - 1 \) for some \( j \).

Remarks. — a) It is known that the real cohomology algebra of the compact, semi-
simple, simply connected Lie group whose complexified Lie algebra is \( \mathfrak{g}_0 \otimes \mathbb{C} \) is an
exterior algebra on \( l \) generators of degrees \( 2k_i + 1 (1 \leq i \leq l) \) (see e.g. [12], where the
Betti numbers are discussed).

b) The property b) mentioned in the course of the proof of (2.2) can also be stated
in the following way: the Jordan normal form of \( \text{ad} \, n \) in \( \mathfrak{g}_0 \) is a direct sum of \( l \) Jordan
matrices, with \( 2k_1 + 1, \ldots, 2k_l + 1 \) rows, respectively.

We now want to investigate the elementary divisors of the homomorphisms \( t_i \).
First an easy special case.

(2.4) Proposition. — We have \( \mathfrak{g}^0/\mathfrak{g}^{-1}(\mathfrak{g}^{-1}) \cong \Delta/\Gamma \), \( \mathfrak{g}^1/\mathfrak{g}^0(\mathfrak{g}^0) \cong \Gamma'/\Delta \).
\( \mathfrak{g}^{-1} \) has as a basis the \( (\epsilon_r)_{r \in S} \) and we have \( t_{-1}(\epsilon_{r}) = 2(s, r)^{-1} s \), which implies
the first assertion, taking into account the fact that $\Gamma$ is generated by the $2(s, s)^{-1}s$ with $s \in S$ (this follows from the remark in [9], p. 16, lines 10-11 from below). $\Gamma'$ has a basis $(f_S)_{S \in S}$ where $(r, f_r) = \delta_r (r, s)$. Let $g_r = \sum_{s \in S} a_{rs} f_s$ be basis vectors of $g^0 = \Delta$ (where $a_{rs} \in \mathbb{Z}$). Then $t_0 (g_r) = -\sum_{s \in S} a_{rs} e_r$. This implies that $g^1 / \rho^0 (g^0) \cong \Gamma' / \Delta$.

(2.5) Corollary. — If $\Delta = \Gamma'$ then $t_{i-1}$ has no elementary divisors and those of $t_0$ are: the prime powers occurring in the decomposition of $l + 1$ for type $A$, 2 for the types $B, D$ ($l$ even), $E_7, 3$ for type $E_6, 4$ for type $D$ ($l$ odd). If $\Delta = \Gamma'$ then $t_0$ and $t_{-1}$ are to be interchanged in the preceding statement.

This follows from the structure of $\Gamma' / \Gamma$, given in (1.4).

We now come to the main result of this section.

(2.6) Theorem. — For $i > 0$ and $i < -1$ $t_i$ has at most one elementary divisor. It is a prime $p$ and its multiplicity is 1. This occurs in the following cases

<table>
<thead>
<tr>
<th>Type</th>
<th>Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>$B_l$</td>
<td>$l \geq 2$</td>
</tr>
<tr>
<td>$C_l$</td>
<td>$l \geq 3$</td>
</tr>
<tr>
<td>$D_l$</td>
<td>$l \geq 4$</td>
</tr>
<tr>
<td>$E_6$</td>
<td>$p = 2, i = 2, 4, \ldots, 2 \left( \frac{l}{2} \right) - 2$</td>
</tr>
<tr>
<td>$E_7$</td>
<td>$p = 2, i = 2, 4, 8, -3, -5, -9$</td>
</tr>
<tr>
<td>$E_8$</td>
<td>$p = 2, i = 2, 4, 8, 14, -3, -5, -9, -15$</td>
</tr>
<tr>

<td>$p = 2, i = 2, 4, 8, -3$</td>
</tr>
<tr>
<td>$G_2$</td>
<td>$p = 2, i = 2, -3$</td>
</tr>
</tbody>
</table>

We shall prove (2.6) by “checking cases”. Before indicating how this can be done, we give a few facts of a more general nature, which are used in the proof. First observe that for $i = 0, -1$ the matrix of $t_i$ with respect to the bases of $g^i, g^{i+1}$ formed by the appropriate $e_r$ is

$$M_i = (N_{s-r, r})_{h(s) = i, h(r) = i}$$

(the roots of height $i$ and $i + 1$ are supposed to be ordered in some way).

We assume that the structure constants $N_{rs}$ satisfy (1.7) b) and (1.9) (if applicable).

(2.7) Lemma. — If all roots of $R$ have the same length, then the elementary divisors of $t_i$ and their multiplicities are the same as those of $t_{-i+1}$ ($i > 0$).

If all roots have the same length, the condition of (1.8) b) is satisfied for all $r, s$. It then follows from (1.8) b) that

$$t_i M_i = - M_{-i+1}$$

($i > 0$),

which implies the assertion of (2.7).

(2.8) A method which we shall often use is the following one. Let $x \in S$ be a fixed simple root. Decompose $g^i = \mathfrak{m}_i^0 + \mathfrak{m}_i^1$, where $\mathfrak{m}_i^0$ is spanned by the $e_r$ such that $r$
contains $s_0$, i.e. that in $r = \sum n_i s_i$ we have $n_i \neq 0$, and where $m_i^l$ is spanned by the other $\epsilon_i$. Decompose $g^{t+1}$ in the same manner. Let $t_0$ denote the restriction of $t_0$ to $m_0$, let $t_1$ denote the induced homomorphism of $m_1$ into $g^{t+1}/m_0^{t+1} \cong m_1^{t+1}$. Suppose first that $t_0$ is an isomorphism of $m_0$ onto $m_1$. Then by (0.3) the elementary divisors of $t_1$ can be found from those of $t_0$. The way in which $t_1$ is constructed shows that it is a mapping of the same kind as $t_0$, but for a root system $R_1$ of lower rank, whose roots are those of $R$ which do not contain $s_0$. In this way we can use induction with respect to the rank $l$. This is one method which we shall use. A second one applies when $t_1$ is an isomorphism. In that case we know by (0.3) that the elementary divisors of $t_1$ can be found from those of $t_0$.

(2.9) We now turn to the proof of (2.6), for which we shall discuss the simple types. These are described in [14] (exposé 19), we use the same description here. We denote in all cases a set of simple roots by $(\tau_0)_{1 \leq i \leq l}$.

Type $A_l$ ($l \geq 1$):

The roots are the vectors $\pm (r_i + \ldots + r_j)$ ($1 \leq i \leq j \leq l$). There are $l - |i| + 1$ roots with height $i$, the highest root is $r_i + \ldots + r_l$. All roots have the same length, all $N_\alpha$ are ±1.

We have to prove that the $t_l (i \neq 0, -1)$ have no elementary divisors. By (2.7) we need only to prove this for $i > 0$.

For every height $i > 0$ there is exactly one root $s_i$ which contains $r_i$ (viz. $s_i = r_i + \ldots + r_j$). It follows immediately that $t_l (s_i) = \pm s_{i+1}$. Moreover if $l \geq 2$ the roots which do not contain $r_i$ form a system of type $A_{l-1}$.

We can now apply the first method of (2.8). It is clear that induction with respect to $l$ gives the result which has to be proved. The starting point $l = 1$ is easy.

Type $B_l$ ($l \geq 2$):

The roots are $\pm r_i, \pm r_{ij}$ with

$$r_{ij} = r_i + \ldots + r_j$$

$$(1 \leq i \leq j \leq l), \quad r_{ij} = r_i + \ldots + r_{j-1} + 2r_j + \ldots + 2r_l$$

$$(1 \leq i < j \leq l).$$

We have

$$h(r_{ij}) = j - i + 1, \quad h(r_{ij}) = 2l - i - j + 2.$$ 

There are $l - i$ roots with height $2i$ or $2i + 1$. The highest root is $r_1 + 2r_2 + \ldots + 2r_l$.

Not all roots have the same length, $N_\alpha = \pm 1$ or ±2.

Again, for each height $i \neq 0$ there is exactly one root $s_i$ which contains $r_i$. We have $s_i = r_{i, l}$ ($1 \leq i \leq l$), $s_i = r_{i+1, l}$ ($l + 1 \leq i \leq 2l - 1$), and $s_{\alpha} = -s_\alpha$.

Moreover, for $l \geq 3$ the roots which do not contain $r_i$ form a root-system of type $B_{l-1}$.

We prove the statement for type $B_l$ contained in (2.6) by induction with respect to $l$. We start with $l = 2$. In this case we have to prove that $t_2$ has an elementary
divisor 2 with multiplicity 1 and that the other \( t_i (i \neq 0, -1) \) do not have elementary divisors. This is an easy check. Suppose that \( l > 2 \) and that we have already proved the assertion for type \( B_{l-1} \). Now we have \( t_i(\epsilon_{ij}) = \pm \epsilon_{i+1} \) if \( i \pm l \), \( t_i(\epsilon_{ij}) = \pm 2 \epsilon_{i+1} \).

The first method of (2.8) establishes the assertion for \( i \neq l \). If \( l \) is even the second method of (2.8) gives the desired result for \( i = l \). Now let \( l \) be odd. Then the roots of height \( l \) are \( r_{l,i}, r'_{l,i} \), \( i \), \( r_{l,i+1}^*, \ldots, r'_{l,i+1}^* \); those with height \( (l+1) \) are \( r'_{l,i}, r''_{l,i-1}, \ldots, r'_{l,i+1}^*, r''_{l,i+1}^* \). Put \( \epsilon_{ij} = \epsilon_{ij}, \epsilon_{ij}^* = \epsilon_{ij}^* \). We then have

\[
\begin{align*}
\left\{ \begin{array}{l}
t_i(\epsilon_{ij}) = \pm 2 \epsilon_{ij}, \quad t_i(\epsilon_{i, \ldots, i+j}) = \pm \epsilon_{i-1, i-1} + \pm 2 \epsilon_{i-i+1} \\
t_i(\epsilon_{i, \ldots, i+j}^*) = \pm \epsilon_{i-1, i-1}^* \pm 2 \epsilon_{i-i+1}^*
\end{array} \right. \quad (i < \frac{1}{2} (l+1)),
\end{align*}
\]

It is now easy to check that \( t_i \) has no elementary divisors. This settles the case \( i > 0 \).

For \( i < 0 \) we put \( g_i = m_i + m_i^* \) as in (2.8), where \( m_i = \mathbb{Z} e_{ij} \). We have

\[
t_i(\epsilon_{ij}) = \pm \epsilon_{i+1} (\text{mod } m_i^*+1)
\]

if \( i \neq -1 \).

Applying (0.3) with \( E = g_i, E_i = \mathbb{Z} e_{ij} \) we get from the induction assumption the assertion about \( t_i \) for \( i < 0, i \neq -l \). The case \( i = -l \) is dealt with as in the case that \( i > 0 \).

Type \( C_i (i \geq 3) \):

The roots are \( \pm r_{ij}, \pm r'_{ij} \), where

\[
\begin{align*}
r_{ij} &= r_i + \ldots + r_j \quad (1 \leq i \leq j \leq l), \\
r'_{ij} &= r_i + \ldots + r_{i-1} + 2r_j + \ldots + 2r_{i-1} + r_i \quad (1 \leq i \leq j \leq l).
\end{align*}
\]

We have

\[
h(r_{ij}) = j - i + 1, \quad h(r'_{ij}) = 2l - i - j + 1.
\]

There are \( l - i \) roots with height \( 2i \) or \( 2i + 1 \). The highest root is \( 2r_1 + \ldots + 2r_{i-1} + r_i \).

Not all roots have the same length, \( N_{r_i} = \pm 1 \) or \( \pm 2 \).

For each height \( i \neq 0 \) there is exactly one root \( s_i \) which contains \( r_1 \), viz. \( s_i = r_i \) \( (1 \leq i \leq l) \), \( s_i = r_i^* \) \( (1 + 1 \leq i \leq 2l - 1) \) and \( s_{-l} = -s_i \).

The statement regarding type \( C_i \) is proved in the same way as that for type \( B_i \), we leave the details to the reader.

Type \( D_i (i \geq 4) \):

The roots are \( \pm r_{ij}, \pm r'_{ij}, \pm r_i \), where

\[
\begin{align*}
r_{ij} &= r_i + \ldots + r_j \quad (1 \leq i \leq j \leq l-1), \\
r'_{ij} &= r_i + \ldots + r_{i-1} + 2r_j + \ldots + 2r_{i-1} + r_{i-1} + r_i \quad (1 \leq i \leq j \leq l-1), \\
r_i &= r_i + \ldots + r_{i-2} + r_{i-1} \quad (1 \leq i \leq l-1).
\end{align*}
\]

We have

\[
h(r_{ij}) = j - i + 1, \quad h(r'_{ij}) = 2l - i - j, \quad h(r_i) = l - i.
\]
There are \( l - i \) roots with height \( 2i < l \) and \( 2i + 1 < l \), there are \( l - i - 1 \) roots with height \( 2i \geq l \) and \( 2i + 1 \geq l \). The highest root is \( r_1 + 2r_2 + \ldots + 2r_{l-2} + r_{l-1} + r_l \), its height is \( 2l - 3 \). All roots have the same length, \( N_{\alpha} = \pm 1 \). So by lemma (2.7) it suffices to prove the part of (2.6) about \( D_l \) only for positive heights \( i \).

For each height \( i > 0 \), \( i = l - 1 \) there is exactly one root \( s_i \) containing \( r_1 \), for \( i = l - 1 \) there are 2 such roots, which we call \( s_{l-1} \) and \( s'_{l-1} \). We have \( s_i = r_{1i} (1 \leq i < l) \), \( s_i = r'_{1i} (l \leq i \leq 2l - 3) \), \( s'_{l-1} = r'_{l-1} \). The roots which are linear combinations of \( r_2, \ldots, r_l \) form a root system of type \( D_{l-1} \) (of type \( A_3 \) if \( l = 4 \)).

We have

\[
t_i(\epsilon_{s_i}) = \pm \epsilon_{s_{i+1}} \quad \text{for } i \neq l - 2,
\]

and

\[
t_{l-1}(\epsilon_{s_{i-1}}) = \pm \epsilon_{s_i}.
\]

Using the first method explained in (2.8) we see that the elementary divisors of \( t_i \) for type \( D_l \) are the same as those of \( t_i \) for type \( D_{l-1} \) (\( A_3 \) for \( l = 4 \)), if \( i \neq l - 2 \).

So it remains to consider the case \( i = l - 2 \). In that case the assertion of (2.6) is: \( t_{l-2} \) has the elementary divisor 2 with multiplicity 1 if \( l \) is even and does not have elementary divisors if \( l \) is odd.

Let \( l \geq 4 \). The roots of height \( l - 2 \) are \( r_{i-1}, r_{i-1}^+, r_{i-1}^-, r_{i+2}^- (3 \leq i < \frac{1}{2}(l + 1)) \), those of height \( l - 1 \) are \( r_{i-1}, r_i^+, r_{i+1}+, r_{i+1}^- (2 \leq i < \frac{1}{2}(l + 1)) \). Put \( \epsilon_{ij}^{(i)} = \epsilon_{ij}^{(i)} \), \( \epsilon_i^{(i)} = \epsilon_i^{(i)} \), \( \epsilon_i^{(i)} = \epsilon_i^{(i)} \), we define \( \epsilon_{ij}^{(i)} = 0 \) if \( i \geq j \).

Assuming (1.9) for the structure constants, we have

\[
t_{l-2}(\epsilon_{i+1}^{(i)}) = -\epsilon_{i+1}^{(i)} - \epsilon_{i+1}^{(i)},
\]

\[
t_{l-2}(\epsilon_{i-1}^{(i)}) = -\epsilon_{i-1}^{(i)} - \epsilon_{i-1}^{(i)},
\]

\[
t_{l-2}(\epsilon_i^{(i)}) = -\epsilon_i^{(i)} - \epsilon_i^{(i)},
\]

\[
t_{l-2}(\epsilon_{i+2}^{(i)}) = -\epsilon_{i+2}^{(i)} - \epsilon_{i+2}^{(i)}.
\]

If \( l \) is odd, \( t_{l-2}(\epsilon_{i+2}^{(i+1)}) = -\epsilon_{i+1}^{(i+1)} \), which is readily seen to imply that \( t_{l-2} \) is surjective; hence has no elementary divisors.

If \( l \) is even, \( t_{l-2} \) maps \( \epsilon_{i+1}^{(i+1)} (i \geq 3) \) in \( -\epsilon_{i+1}^{(i+1)} \) modulo the sublattice of \( g_{l-1} \) generated by \( r_{i-1}, r_i^+, r_{i+1}^- (2 \leq j \leq l) \). From this one infers that the elementary divisors of \( t_{l-2} \) are the same as those of \( t_2 \) for type \( D_2 \). In this case the preceding formulas are easily seen to imply that there is only an elementary divisor 2, with multiplicity 1.

Type \( E_l \):

There is a basis \( (x_i)_{1 \leq i \leq 6} \) of \( V \) such that the roots are \( x_i - x_j (i \neq j) \), \( \pm (x_i + x_j + x_k - s) \) (\( i, j, k \) distinct) and \( \pm s \), where \( s = (1/3) \sum_{i=1}^6 x_i \). The simple roots are then \( r_i = x_i - x_{i+1}, (1 \leq i \leq 5) \), \( r_6 = x_4 + x_5 + x_6 - s \). One can now write down all
positive roots, expressed as linear combinations of the simple ones. The result is given in table I (appendix). The highest root is $r_1 + 2r_2 + 3r_3 + 2r_4 + r_5 + 2r_6$.

All $N_i$ are $\pm 1$, the roots have the same length. So by lemma (2.7) it is sufficient to consider positive heights.

One sees by inspection of table I that, except for $i = 2, 3$, the following situation prevails: the bases $(e_r)$ of $g^i$ and $g^{i+1}$ can be numbered such (say $e_1, \ldots, e_r, f_1, \ldots, f_t$) that we have $t(e_r) = \pm f_i + a$ linear combination of $f_1, \ldots, f_{r-1}$.

It is then obvious that $t_4$ has no elementary divisors. So only $i = 2, 3$ remain. If $i = 2$ we apply the first method of (2.8), with $s = r_1$. There is only one root of height 2 or 3 containing $r_1$, and the roots not containing $r_1$ form a root system of type $D_8$. Hence the case of height 2 for type $E_6$ can be reduced to height 2 for type $D_8$, which has already been dealt with.

In the remaining case $i = 3$ we must make a computation. Making use of table I, it is easy to write down the matrix $M_3$ for this case (which has 5 rows and columns). Its entries are 0 or $-1$ (by (1.9)). There is no difficulty in finding its determinant, it turns out to be $\pm 3$. This implies that $t_3$ has an elementary divisor 3 with multiplicity 1, which proves the assertion about $E_8$. For $E_7$ and $E_8$ the argument is of the same nature.

Type $E_7$:

There is a basis $(e_i)_{1 \leq i \leq 7}$ of $V$ such that the roots are $x_i - x_j (i \neq j)$, $\pm (x_i + x_j + x_k - s)$ ($i, j, k$ distinct), $\pm (s - x_i)$, where $s = (1/3) \sum x_i$. The simple roots are then $r_1 = x_i - x_{i+1}$ ($1 \leq i \leq 6$), $r_7 = x_3 + x_6 + x_7 - s$. In table II the reader will find the positive roots, expressed in the simple ones.

The highest root is $r_1 + 2r_2 + 3r_3 + 2r_4 + 3r_5 + 2r_6 + 2r_7$. All roots have the same length, the $N_i$ are $\pm 1$. So we need only consider positive heights.

Again, as for $E_8$, a verification based on the use of table II shows that one only needs to consider the cases $i = 2, 3, 4, 8$. The cases $i = 2, 3$ are reduced to the corresponding cases for type $E_8$ (there is only one root of height 2 or 3 containing $r_1$ and the roots not containing $r_1$ correspond to those of a system of type $E_8$). For $i = 4$ we apply the first method of (2.8) with $s = r_8$. The roots not containing $r_8$ form a system of type $D_8$, we may then reduce the case $i = 4$ for $E_7$ to the corresponding case for $D_8$, which has been dealt with. In the remaining case $i = 8$ a simple computation shows that $\det M_8 = \pm 2$. This settles type $E_7$.

Type $E_8$:

$V$ is generated by vectors $(e_i)_{1 \leq i \leq 9}$ with sum zero, such that the roots are $x_i - x_j (i \neq j)$, $\pm (x_i + x_j + x_k)$ ($i, j, k$ distinct). The simple roots are $r_i = x_i - x_{i+1}$ ($1 \leq i \leq 7$), $r_8 = x_9 + x_8 + x_9$. In table III we have given the positive roots, expressed in the simple ones.
The highest root is $2r_1 + 3r_2 + 4r_3 + 5r_4 + 6r_5 + 4r_6 + 2r_7 + 3r_8$. All roots have the same length, $N_{r_i} = \pm 1$. We need only consider positive heights.

For $i = 2, 3, 4, 5, 8, 9, 14$ a verification using table III shows that $t_i$ has no elementary divisors.

In the cases $i = 2, 3, 4, 8$ we can reduce, considering the roots containing $r_1$, type $E_8$ to type $E_7$.

In the remaining cases $i = 5, 9, 14$ one has to calculate the determinant of $M_i$. The method is the same as in the previous cases. The result is that in these cases $\det(M_i)$ is, in absolute value, $5, 3, 2$, respectively. This settles type $E_8$.

Type $F_4$:

There is a basis $(x_i)_{1 \leq i \leq 4}$ such that the roots are $x_i - x_j (i \neq j)$, $\pm x_i$, $\pm (x_i + x_j) (i \neq j)$, $(1/2) \sum_{i=1}^{4} \xi_i x_i$, where $\xi_i = \pm 1$. The simple roots are $r_1 = x_1 - x_2$, $r_2 = x_2 - x_3$, $r_3 = x_3$, $r_4 = (1/2) (x_4 - x_1 - x_2 - x_3)$.

The positive roots, expressed in the simple ones, are given in table IV. The highest root is $2r_1 + 3r_2 + 4r_3 + 2r_4$.

The roots do not have all the same length, $N_{x_2} = \pm 1$ or $\pm 2$. For $i > 0$ one checks, using table IV, that except for $i = 3$, we may take bases $\psi_1, \ldots, \psi_6$ and $f_1, \ldots, f_i$ of $g^i$ and $g^{i+1}$ such that

$$t_i(x_2) = \alpha f_k + \text{a linear combination of } f_1, \ldots, f_{k-1},$$

where $\alpha = \pm 1$ or $\pm 2$.

One checks that $\alpha = \pm 2$ can only happen if $i = 2, 4, 8$. It is easily verified in these cases that the assertion of (2.6) holds. For $i < -1$ a similar argument gives the desired result if $i = -4$. There remain the cases $i = 3, -4$. There again we calculate a determinant. In this case we have to use a more complicated argument, because the $|N_{x_i}|$ may have different values.

First let $i = 3$. We then find without difficulty that

$$\pm \det M_3 = N_r r_2 r_3 N_r r_2 r_3 N_r r_2 N_r r_2 N_r r_2 N_r r_2,$$

where $r = r_2 + r_3$ (which is a root).

Now by Jacobi's identity (viz. the last formula (2)) we have

$$(8) \begin{cases} N_{r+r_2 r_3} N_{r} r_2 = N_{r+r_2 r_3} N_{r} r_2 \\ N_{r+r_2 r_3} N_{r} r_3 = N_{r+r_2 r_3} N_{r} r_3 \\ N_{r+r_2 r_3} N_{r} r_3 - N_{r+r_2 r_3} N_{r} r_3 + N_{r} N_{r} r_3 = 0, \end{cases}$$

where $s = r_3 + r_4$.

Now it follows from lemma (1.7) that $N_{r} r_3 = \pm 1$. Then the first 2 formulas (8) give

$$N_{r+r_2 r_3} N_{r+r_2 r_3} N_{r+r_2 r_3} = N_{r+r_2 r_3} N_{r+r_2 r_3} N_{r+r_2 r_3} N_{r+r_2 r_3} N_{r+r_2 r_3}.$$
It follows that
\[ \pm \det M_3 = N_{r+r_s}N_{r+r_s}N_{r+r_s}(N_{r+r_s}N_{r+r_s}N_{r+r_s} + N_{r+r_s}N_{r+r_s}), \]
which (using again lemma (1.7) b)) yields
\[ \pm \det M_3 = N_{r+r_s}N_{r+r_s} + N_{r+r_s}N_{r+r_s} = 2N_{r+r_s}N_{r+r_s}N_{r+r_s} - N_{r+r_s}N_{r+r_s}, \]
by the last formula (8).

Another application of Jacobi's identity gives
\[ N_{s,r} - N_{t,r} = N_{s,r} - N_{t,r}. \]
Since \( N_{s,r} = \pm 1 \), we have
\[ \pm \det M_3 = 2N_{r+s}N_{r+r_s}N_{r+r_s} - N_{r+r_s}N_{r+r_s}N_{r+r_s} \]
\[ = N_{r+s}(2N_{r+s}N_{r+r_s}N_{r+r_s} - N_{r+r_s}N_{r+r_s}). \]
Now \( N_{r+r_s}N_{r+r_s} = -N_{r+r_s}N_{r+r_s} \) (again by Jacobi's identity), and these integers as well as \( N_{r+s} \) are \( \pm 1 \) (by lemma (1.7) b)). So \( \det M_3 = \pm 3 \), which settles the case \( i = 3 \).

Finally for \( i = -4 \), we find an expression for \( \det M_{-4} \) like the one for \( \det M_3 \) with which we started. Using lemma (1.8) a) one gets

\[ \det M_{-4} = \pm \det M_3 = 2N_{r+s}N_{r+r_s}N_{r+r_s} - N_{r+r_s}N_{r+r_s}N_{r+r_s} \]
\[ = N_{r+s}(2N_{r+r_s}N_{r+r_s} - N_{r+r_s}N_{r+r_s}). \]

if \( r \) and \( s \) are positive roots (such that \( s - r \) is one). By lemma (1.7) b) one knows \( |N_{r+s}| \).

Now (9) allows one to compare the expression which one finds for \( \det M_{-4} \) with the above one for \( \det M_3 \), the result is that both have the same absolute value, which has been found to be 3.

**Type \( G_2 \):**

The roots are \( \pm r_1, \pm r_2, \pm (r_1 + r_2), \pm (r_1 + 2r_2), \pm (r_1 + 3r_2), \pm (2r_1 + 3r_2) \).

The highest root is \( 2r_1 + 3r_2 \). We have \( N_{r+s} = 0, \pm 1, \pm 2, \pm 3 \). There is no difficulty, using lemma (1.7) b), to verify the assertion of theorem (2.6). This finishes the proof of theorem (2.6).

(2.10) We shall say that \( p \) is a **bad prime** for the simple root system \( R \) or for the corresponding Lie algebra \( \mathfrak{g} \) if \( p \) divides a coefficient of the highest root of \( R \) (this obviously does not depend on \( \Delta \)).

If \( R \) is not simple, then we say that \( p \) is a bad prime if it is one for one of the simple components of \( R \). Otherwise \( p \) is called a **good prime**. In the course of the proof of (2.6) we have indicated the highest roots of the various types. From this it follows that the bad primes are for the simples types:

\[ A_1: \text{none}; \quad B_1, C_1, D_1: p = 2; \quad E_6, E_7, F_4, G_2: p = 2, 3; \quad E_8: p = 2, 3, 5. \]

From (2.6) and its proof we can now extract various characterizations of the bad primes (\( R \) is supposed to be simple).
Theorem. — \( p \) is a bad prime for \( g \) if and only if one of the following conditions holds:

(i) \( t_\ell \) has an elementary divisor \( p \) for some \( i > 0 \);
(ii) \( t_\ell \) has an elementary divisor (which is then \( p \) with multiplicity 1);
(iii) \( t_\ell = t_{\ell+1} \);
(iv) \( t_\ell = l - 1 \) if \( 2 \leq i \leq p + 1 \).

(As in (1.10), \( l_i \) denotes the number of roots with height \( i \).

(i) and (ii) are read off from the statement of theorem (2.6). (iii) and (iv) are read off from the explicit structure of the root systems of the simple types. This is an entirely straightforward verification (using tables I, II, III, IV for types \( E_6, E_7, E_8, F_4 \) and the results cited in (2.9) for the other types).

Proposition. — If \( t_{\ell} (i > 0) \) has an elementary divisor, then \( l_{\ell} = l_{\ell+1} \).

This is also proved by using (2.6) and checking the possible cases.

It would be interesting to have a priori proofs of (2.11) and (2.12).

3. On the torsion of compact Lie groups.

In this paragraph we denote by \( G \) a compact, semi-simple, simply connected Lie group. We denote by \( g \) the Lie-algebra over \( \mathbb{Z} \) defined in § 1, defined by the root system of \( G \). For definiteness we assume \( g \) to be of "simply connected" type (\( \Delta = \Gamma' \)).

It is known (see [6]) that if \( R \) is simple, \( G \) has a \( p \)-torsion exactly in the following cases:

\( p = 2 \), types \( B_i, D_i, E_6, E_7, E_8, F_4, G_2 \);
\( p = 3 \), types \( E_6, E_7, E_8, F_4, G_2 \);
\( p = 5 \), type \( E_6 \).

Combining this information with that given by theorem (2.6) one obtains the following result (in which we use for \( g \) the notations of § 2).

Theorem. — Let \( G \) be a compact, semi-simple, simply connected Lie group. Then \( G \) has \( p \)-torsion if and only if \( t_{-(p+1)} \) has an elementary divisor.

For the simple types this is checked at once; the extension to the general case is then immediate.

(3.2) (3.2) indicates that there is a connection between the topology of \( G \) and the structure of \( g \). We shall give now a few more results which point in the same direction. All these results are obtained by "checking cases". We first recall some facts about the structure of the cohomology algebra \( H^*(G, k) \) for a field \( k \). It is known that this algebra is a Hopf algebra. The structure theory of Hopf algebras (see e.g. [4]) then implies that

\[ H^*(G, k) = k[X_1, \ldots, X_m]/(X_1^{d(1)}, \ldots, X_m^{d(m)}), \]

where \( k[X_1, \ldots, X_m] \) is a graded anticommutative polynomial algebra with generators \( X_i \) of degree \( k(i) (1 \leq i \leq m) \). The \( d(i) \) are 2 if \( \text{char}(k) = 0 \) and are either 2 or a power of \( \text{char}(k) \) if \( \text{char}(k) \neq 0 \). We now list some known results.
a) If char(k) = 0, then $H^*(G, k)$ is an exterior algebra on $l$ generators (where $l = \text{rank } G$). These generators have degrees $h(i) = 2k_i + 1$, where the $k_i$ the integers defined in (2.3). They can be read off from the root system $R$, as follows from (2.3). These matters are dealt with in [12].

b) Take now $k = \mathbb{F}_p$, the prime field with $p$ elements. If $G$ has $p$-torsion, then we assume the $X_i$ to be numbered such that $d(1), \ldots, d(a)$ are $>2$ and $d(a + 1) = \ldots = d(m) = 2$. We call

$$k[X_1, \ldots, X_n]/(X_1^{(0)}, \ldots, X_n^{(0)})$$

the *extraordinary part* of the cohomology algebra $H^*(G, \mathbb{F}_p)$.

First let $p$ be odd. Let $G$ be simple. In the cases where $p$-torsion occurs (which are enumerated above) the extraordinary part of $H^*(G, \mathbb{F}_p)$ is known (see [5] for $F_4$, [2] and [6] for $E_6, E_7, E_8$), the following holds: all $d(i)$ $(1 \leq i \leq a)$ are equal to $p$, the $h(i)$ are respectively,

- $8$ if $p = 3$, for types $E_6, E_7, F_4$,
- $8,20$ if $p = 3$, for type $E_8$,
- $12$ if $p = 5$, for type $E_6$.

Comparing this with the results stated in (2.6) we obtain the following statement.

**Proposition.** — Let $G$ be a compact, simple, simply connected Lie group. If $p$ is odd, the extraordinary part of $H^*(G, \mathbb{F}_p)$ is $k[X_1, \ldots, X_n]/(X_1^{(0)}, \ldots, X_n^{(0)})$ where $h(i)$ runs through the integers $\nu_j$ such that $t_{-i}$ has an elementary divisor $p$.

**(3.5)** For $p = 2$ a corresponding statement is not true. For then the $d(i)$ occurring in the extraordinary part of $H^*(G, \mathbb{F}_2)$ are not always equal (this is the case, for example, in type $E_8$, as follows from the results of [3]). The known results (see [1], [3], [5]) show however that the following holds: the degrees $h(i)$ $(1 \leq i \leq a)$ occurring in the extraordinary part of $H^*(G, \mathbb{F}_2)$ are the integers $j$ such that $t_{-i}$ has an elementary divisor $2$.

4. The centralizer of a regular unipotent element of a semi-simple algebraic group.

**(4.1)** In this paragraph we shall give an application of the results of § 2 to a problem in the theory of algebraic groups over an algebraically closed ground field $k$.

We denote now by $G$ an algebraic group over $k$ (= smooth affine group scheme of finite type over $k$) which is connected and semi-simple. For the standard facts about such groups we refer to [14], to which we conform. We recall some notions. Let $T$ be a maximal torus in $G$. With $G$ there is associated a root-system $R$ (in the sense of § 1), the $\alpha \in R$ are rational characters of $T$. For any $\alpha \in R$, there exists a unipotent subgroup $X_\alpha$ of $G$, which is isomorphic over $k$ to the additive group $G_a$ and which is normalized by $T$. Fixing a set of simple roots, let $U$ be the subgroup of $G$ generated by the $X_\alpha$ with $\alpha > 0$, let $B$ be the group generated by $T$ and $U$. The group $B$ is then a Borel (= maximal connected solvable) subgroup of $G$, $U$ is a maximal connected unipotent subgroup of $G$. 

The Borel subgroups of $G$ are conjugate, so are the maximal connected unipotent subgroups.

In the next result the structure constants $N_{rs}$ will occur of a Lie algebra $g$ discussed in § 1, belonging to the root-system $R$ of $G$. These structure constants are assumed to be integers satisfying (1.7) $b)$. We then have the following important result, due to Chevalley (see [9] and [10]).

(4.2) Proposition. — There exist isomorphisms $x_r : G \rightarrow X_r (r \in R)$ such that if $r + s = o$ we have for $\xi, \eta \in G_r$,

$$x_r(\xi)x_s(\eta)x_r(\xi)^{-1}x_s(\eta)^{-1} = \prod_{i,j > 0} x_{ir + js}(C_{ijrs})^i \eta^j,$$

where the product on the righthand side is over the integral linear combinations of $r$ and $s$ which are contained in $R$, taken in a suitable order and where the $C_{ijrs}$ are integers with $C_{1rs} = N_{rs}$.

We shall apply this to obtain information about the structure of $U$. Henceforth the $x_r$ will always denote isomorphisms $G_r \rightarrow X_r$ with the properties of (4.2).

(4.3) Lemma. — Let $S$ be the set of simple roots of $R$ defining the ordering of $R$. Let $x = \prod_{r \in S} x_r(\xi_r)$ (the product being taken in some order) be an element of $U$ such that $\xi_r + o$ for $r \in S$. Then $x$ is contained in exactly one Borel subgroup of $G$, namely $B$. The centralizer $G_x$ of $x$ is the direct product of the center $G$ of $G$ and $U_x$, the centralizer of $x$ in $U$.

The first assertion is proved in [17] (lemma 3.2), for the convenience of the reader we indicate the proof. Suppose $gxg^{-1} \in B$ for $g \in G$. Applying Bruhat's lemma ([14], exposé 13, th. 3, Cor. 1) we see that we may take $g = a_u b$, where $b \in B$ and where $a_u$ is a representative in $G$ of the element $w \in W = N(T)/T$ ($N(T)$ denoting the normalizer of $T$ in $G$). If $x$ satisfies the condition of (4.3) then (4.2) implies (together with the facts that $B = TU$ and that $T$ normalizes all $X_r$) that $bxb^{-1}$ satisfies the same conditions. It suffices then to take $g = a_u$. However since $a_u X_r a_u^{-1} = X_{w(r)}$ it follows that $w(s) = o$ for all $s \in S$. This is known to imply that $w = 1$. Hence $gxg^{-1} \in B$ implies $g \in B$, which proves the first assertion.

As to the second assertion, the preceding argument shows that $G_x = B$. Take $g \in G_x$ and write $g = tu (t \in T, u \in U)$. It is well-known that

$$tx_r(\xi)t^{-1} = x_r(r(t)\xi).$$

Using this it follows that $s(t) = 1$ for all $s \in S$. This implies that $t \in C$.

Let $X$ denote the set of all unipotent elements of $G$. Let $l$ be the rank of $G$, i.e. the dimension of the maximal tori of $G$.

(4.4) Proposition. — $X$ is an irreducible Zariski-closed subset of $G$ of dimension $\dim G - l$.

Since every unipotent element of $G$ is conjugate to an element of $U$, $X$ is the union of the conjugates of $U$. Then (4.3) implies that the normalizer of $U$ in $G$ is the same as the normalizer of $B$ in $G$, which is $B$ itself. Application of a well-known result ([14], exposé 6, lemma 5, a more general version is in [15], exposé XIII), taking into account (4.3) and the fact that $G/B$ is a complete variety, proves that $X$ is closed and
has the asserted dimension. The irreducibility of $X$ follows easily from the proof of the cited result.

For $x \in G$, let $G_x$ denote its centralizer in $G$.

(4.5) Proposition. — For any $x \in G$ we have $\dim G_x \geq l$.

If $x$ is unipotent this follows from (4.4): then the orbit of $x$ in $X$ under the adjoint action of $G$ has dimension $\leq \dim G - l$, hence $\dim G_x \geq l$.

If $x$ is arbitrary, write $x = su$ (where $s$ and $u$ are the semi-simple and unipotent parts of $x$). Then the identity component $G^0$ of $G$ is a reductive group (i.e. a connected algebraic group whose radical is a torus) and the centralizer of $x$ in $G$ coincides with that of $u$ in $G_s$. Now $u \in G^0_s$ ([14], exp. 6, cor. 2 of Th. 6). We can then apply the statement for $x$ unipotent to $G^0_s$ modulo its radical.

(4.6) We define an element $x$ of $G$ to be regular if its centralizer $G_x$ has dimension $l$.

The regular elements of a semi-simple group are the subject of [17], where various characterizations and properties are discussed. One of the crucial points of [17] is the proof of the existence of regular unipotent elements for any semi-simple $G$. We shall show that the results of § 2 of this paper enable one to give a different existence proof (however under some restrictions on the characteristic of $k$). Moreover with the results of § 2 one can get information about the connectedness of the centralizer $G_x$ of a regular unipotent element $x$. The study of these connectedness questions is the main object of this paragraph.

(4.7) Lemma. — Suppose that $G$ contains a regular unipotent element. Then any element $x \in U$ with the property of (4.3) is regular. Two regular unipotent elements are conjugate.

This follows from Theorem 3.3 of [17]. A direct proof is as follows: suppose that $y = \prod_{i \geq 0} x_i(z_i) \in U$ is regular. The set $Y$ of conjugates $wu^{-1} (u \in U)$ of $y$ in $U$ is closed in $U$ by a theorem of Rosenlicht (Trans. Am. Math. Soc., 101 (1961), p. 221), moreover it is clear that $\dim Y \geq \dim U - l$. On the other hand it follows from (4.2) that if $z = \prod_{i > 0} x_i(\gamma_i) \in Y$, we have $\gamma_i = z_i$ for $s \in S$. It follows that $\dim Y = \dim U - l$ and that $Y$ is precisely the set of elements $z$ satisfying this condition. In particular, $u = \prod_{s \in S} x_s(z_s)$ lies in $Y$ and hence is regular. Now if $\xi_{s_0} = 0$ for some $s_0 \in S$, there is a non-trivial subtorus of $T$ which centralizes $u$, therefore $\dim G_u \geq l + 1$, which contradicts the regularity of $u$. Hence, all $\xi_s$ are $\neq 0$ and the first assertion follows.

The second assertion can be derived from the first one. Another proof is as follows: let $x$ and $y$ be regular unipotents. Consider their orbits (under adjoint action of $G$) in the set $X$ of unipotent elements. Because of dimensions, these orbits contain Zariski-open subsets of $X$. $X$ being irreducible, these open sets have a non-empty intersection and the conjugacy of $x$ and $y$ follows.

(4.8) It follows from (4.7) that, if regular unipotents exist,

$$v = \prod_{s \in S} x_s(t)$$

(the product taken in some order) is a typical one.
From (4.3) it follows that $v$ is contained in exactly one Borel subgroup, namely $B$. We shall now investigate, generally, the group $U_i$.

Denote by $U_i$ the normal subgroup of $U$ generated by the $X_r$ with $h(r) \geq i$ ($i \geq 1$). We have $U_i \supset U_{i+1}$, $U_i = U$, $U_n = \{e\}$ for large $n$. $U_i/U_{i+1}$ is an abelian algebraic group, isomorphic to $(G_\alpha)^i$ (where, as in § 2, $l_i$ is the number of positive roots $r$ with height $i$). All this follows from (4.2).

Put for $i \geq 1$,

$$V_i = \{u \in U | vu^{-1}u^{-1} \in U_{i+1}\},$$

this is a closed subgroup of $U_i$ containing $U_i$. Let $W_i$ be the canonical image of $V_i$ in $U/U_i$. $W_i$ is a unipotent algebraic group over $k$. The canonical homomorphism $U_i/U_{i+1} \to U_i/U_i$ induces a homomorphism

$$f_i : W_{i+1} \to W_i.$$

$W_i$ is reduced to the identity on the other hand for sufficiently large $n$ we have $W_n = U_i$.

We now study $\ker f_i$ and $\text{Im} f_i$. Let $w \in \ker f_i$. Then $w$ is the coset of an element

$$u = \prod_{h(r)=i} x_r(x_r)$$

modulo $U_{i+1}$.

Using (4.2) one sees that for an $u$ of this form one has

$$vu^{-1}u^{-1} = \prod_{h(r)=i+1} x_r(x_r) \mod U_{i+2},$$

where

$$\eta_r = \sum_{s \in S} N_{s_r} x_r(x_r).$$

Here $s$ runs through the set $S$ of simple roots, the $N_{s_r}$ are the structure constants of the Lie algebra $g$ belonging to $R$ (with the convention that $N_{s-r} = 0$ if $r - s$ is not a root).

If $w \in W_{i+1}$, we have $vu^{-1}u^{-1} \in U_{i+2}$, hence the $x_r$ have to satisfy the linear equations obtained by putting the $\eta_r$ in (11) equal to 0.

Next $\text{Im} f_i$. Map $V_i$ homomorphically into $U_i/U_{i+2}$ by sending $u \in V_i$ into $vu^{-1}u^{-1}$. Under this homomorphism $U_i$ is mapped onto a subgroup $U'_{i+1}/U_{i+2}$ of $U_{i+1}/U_{i+2}$, where $U'_{i+1}$ denotes the group generated by $U_{i+2}$ and the elements

$$\prod_{h(r)=i+1} x_r(x_r),$$

with $x_r$ of the form (11).

By passing to quotients one gets a homomorphism of $W_i$ into $U_{i+1}/U_{i+1}$. It follows at once that the kernel of this homomorphism is $\text{Im} f_i$.

One gets in this way the following inequality

$$(12) \dim \text{Im} f_i \geq \dim W_i - \dim U_{i+1}/U_{i+1}.$$
(4.9) shows that the matrices $M_i$ defined by (6) enter the picture here. We now tie up the problems considered here with the results of § 2. Let $g$ be the Lie-algebra of the type of § 2, whose root system is that of $G$ (the choice of $\Delta$ is immaterial).

Put $g_k = g \otimes_k k$, $g^*_k = g^* \otimes_k k$, $t_{i,k} = t_i \otimes 1$. Let $p$ be the characteristic of $k$. Define

$$l_{i,p} = \text{rank } t_{i,k}$$

(this depends only on the characteristic of $k$), then

$$\dim (\text{Ker } t_{i,k}) = l_i - l_{i,p}.$$  

(2.2) asserts that $l_{i,0} = l_{i+1}$, (2.11) asserts that $l_{i,p} = l_{i+1}$ is $p$ is a good prime for $g$.

(4.10) Proposition. — a) $\text{Ker } f_i$ is isomorphic to $(G_k)^{l_i - l_{i,p}}$; b) $\dim \text{Im } f_i \geq \dim W_i - l_{i+1} + l_{i,p}$.

In fact, both of these results are direct consequences of what was established in (4.8). For example, b) is another way of writing (12). (Actually, equality holds in b), as follows from [17]. We will use this in the proof of (4.12).)

We can now prove the main results of this paragraph. We shall say that a prime is a good (or bad) prime for $G$ if it is a good (or bad) prime for its root system $R$ (see (2.10)). $p$ always denotes the characteristic of $k$.

(4.11) Theorem. — Let $p$ be o or a good prime for $G$. Then there exist regular unipotent elements in $G$. The centralizer of a regular unipotent element is the direct product of the center of $G$ and a connected unipotent subgroup.

It has already been established in (4.7) that we only need to prove that the element $v$ of (10) is regular. Our assumption about $p$ implies by (2.11) that $l_{i,p} = l_{i+1}$, then (4.10) b) shows that $f_i$ is surjective and (4.10) a) shows that $\dim U_i = \sum_{i} (l_i - l_{i+1}) = l$.

The connectedness statement also follows: assuming $W_i$ to be connected, the surjectivity of $f_i$ and the fact that $\text{Ker } f_i$ is connected (it is a vector group) implies that $W_{i+1}$ is connected. Since $W_1 = \{e\}$, $W_n = U_e$ for large $n$, $U_e$ is connected.

The counterpart of (4.11) for bad primes is

(4.12) Theorem. — Let $p$ be a bad prime for $G$. Then there exist regular unipotent elements in $G$. A regular unipotent element is not contained in the identity component of its centralizer, hence the centralizer of a regular unipotent element is the direct product of the center of $G$ and a non-connected unipotent subgroup.

The fact that regular unipotent elements exist in all cases has been established by Steinberg ([17], § 4) by a different method. We will use this now, to prove the other statements of (4.12).

Let $v$ be the element defined by (10). We know by (4.7) that $v$ is regular, hence $\dim U_e = l$. From (4.10) one infers that

$$\dim W_{i+1} - \dim \text{Ker } f_i \geq \dim W_i - l_{i+1} + l_{i,p},$$

hence by (4.10) a)

$$\dim W_{i+1} - \dim W_i \geq l_i - l_{i+1},$$
whence
\[ l = \dim U_v = \sum (\dim W_{i+1} - \dim W_i) \geq \sum (l_i - l_{i+1}) = l. \]

It follows that
\[ \dim \text{Im} f_i = \dim W_i - l_{i+1} + l_{p}, \quad \dim W_{i+1} = \dim W_i = l_i - l_{i+1} \]
for all \( i \geq 1 \).

If \( p \) is a bad prime we know from (2.11) that \( t_i \) has an elementary divisor for some \( i \) and then we read off from (2.6) that \( l_{p, i} = l_{p, i+1} = l - 1 \) for \( i = 1, \ldots, p - 1 \) and \( l_{p, p} = l_{p+1} - 1 = l - 2 \) (where \( l = \text{rank} G \)). Then (13) implies that \( \dim W_i = 1 \) for \( 2 \leq i \leq p \). Moreover it also follows from the first formula (13) that \( f_i \) is surjective for \( i = 1, \ldots, p - 1 \).

We now obtain from the first formula (13)
\[ \dim \text{Im} f_p = 0, \]
so \( f_p(W_{p+1}) \) is a finite group. A fortiori the canonical image of \( U_v \) in \( U/U_p \) is a finite group. This image contains the coset of \( v \) modulo \( U_p \), which is not the identity element (since \( v \notin U_p \)). It follows that \( v \) is not contained in the identity component \( U_v \) of \( U_v \).

This proves (4.12)

(4.13) **Remarks.** — a) It would be interesting to know the exact order of \( U_v/U_p \) in the case considered in (4.12). Of course this order is a \( p \)-power.

The only result in this direction which is known to the author (and which will be stated here without proof) is the following one. Suppose that there is exactly one \( i > 0 \) for which \( t_i \) has an elementary divisor \( p \). Then \( U_v/U_p \) has order \( p \). This result covers the following cases of a simple \( G \): \( p = 2 \), types \( B_2, B_3, E_7, G_2 \); \( p = 3 \), types \( E_6, E_7, F_4, G_2 \); \( p = 5 \), types \( E_6 \).

b) That regular unipotent elements behave differently in low characteristics was first brought to the author's attention by J. Tits.

From (4.11) one can derive the following result about semi-simple groups over nonalgebraically closed ground fields.

(4.14) **Theorem.** — Let \( k \) be a perfect field. Suppose that \( G \) is a semi-simple algebraic group of adjoint type, defined over \( k \), suppose that the characteristic \( p \) of \( k \) is \( 0 \) or a good prime for \( G \). Let \( G(k) \) denote the group of \( k \)-rational points of \( G \). Then any two regular unipotent elements in \( G(k) \) are conjugate in \( G(k) \).

If \( G(k) \) does not contain any regular unipotent element of \( G \), the assertion is vacuous. Assume now that \( x, y \in G(k) \) are regular unipotent elements of \( G(k) \).

By (4.11), the centralizer \( G_e \) of \( x \) is a connected unipotent subgroup of \( G \). \( x \) being rational over the perfect field \( k \), it is well-known that \( G_e \) is defined over \( k \). Put
\[ P = \{ g \in G | gxg^{-1} = y \} \]
By (4.7) $P$ is not empty. Hence $P$ is a principal homogeneous space of $G_x$, which is defined over $k$. $G_x$ being connected and unipotent and $k$ being perfect, $P$ contains a point $g \in G(k)$ (see [16], III-8, prop. 6). This proves our assertion.

(4.15) Remarks. — a) It seems likely that the condition for $k$ to be perfect can be dropped from (4.14). Since the result about principal homogeneous spaces, used in the proof of (4.14), is false for non-perfect fields (counterexamples are in [16], III-16), the proof does not carry over.

b) From [17], Theorem 1.6, it follows that $G(k)$ contains regular unipotent elements either if $G$ is split over $k$ or if $G$ contains a Borel subgroup over $k$ (the quoted result gives the existence of regular unipotent elements if $G$ contains a Borel subgroup over $k$ only if $G$ does not have a component of type $A_n$ with $n$ even; this restriction can however be removed).

c) If $p$ is a bad prime for $G$ the argument used in the proof of (4.13) shows that the number of conjugacy classes of regular unipotent elements of $G(k)$ is either 0 or the number of elements of $H^1(k, G_x/G_k^0)$. It can be shown that the number of elements of $H^1(k, G_x/G_k^0)$ is at least 2. Consequently, if $k$ is a perfect field, the condition that $p$ is a good prime is also necessary for the conjugacy statement of (4.14) (provided, of course, that $G(k)$ contains regular unipotent elements).

5. Regular nilpotent elements in the Lie algebra of a semi-simple algebraic group.

(5.1) As in § 4, let $G$ denote a connected, semi-simple, linear algebraic group over the algebraically closed field $k$. We consider now the Lie algebra of $G$. It is known that this Lie algebra is isomorphic to $g \otimes_k k$, where $g$ is of the type discussed in § 2 (its root system $R$ is that of $G$). However, to abbreviate notations, we write throughout this paragraph $g$ instead of $g \otimes_k k$.

Let $T, U, B, X, Y$ have the same meaning as in § 4. The structure of $g$ is then as follows. $g$ is a direct sum

$$g = t + \sum_{r \in \mathbb{R}} k \epsilon_r$$

where $t$ is the Lie algebra of $T$ and $k \epsilon_r$ that of $X_r$ (both identified with a subalgebra of $g$). With the notations of § 2, $t$ corresponds to $A \otimes_k k$ and $\epsilon_r$ to $\epsilon_r \otimes 1$.

The Lie algebra of $B$ is

$$b = t + \sum_{r > 0} k \epsilon_r,$$

that of $U$ is

$$u = \sum_{r > 0} \epsilon_r.$$
We shall say that \( x \in \mathfrak{g} \) is nilpotent if \( x \) is contained in the Lie algebra of a connected unipotent subgroup \( H \) of \( G \). Since \( H \) is conjugate to a subgroup of \( U \), \( x \) is nilpotent if and only if \( \text{Ad}(g)x \in \mathfrak{u} \) for some \( g \in G \). We shall give presently some results about nilpotent elements in \( \mathfrak{g} \), similar to those proved in § 4 for unipotent elements in groups.

(5.2) Remarks. — a) The definition of a nilpotent element, given above, is the most convenient one for our purposes here. However, because of the definition of semi-simple and unipotent elements in algebraic groups ([14], exposé 4, no 4), another way of defining nilpotent elements in the Lie algebra \( \mathfrak{g} \) of any connected linear algebraic group \( G \) (semi-simple or not) over the algebraically closed field \( k \) would be the following one: Suppose \( G \) is a subgroup of \( \text{GL}(n, k) \), then \( \mathfrak{g} \) is a subalgebra of the Lie algebra \( \mathfrak{gl}(n, k) \), in which the notion of nilpotent element is known. Define then \( x \in \mathfrak{g} \) to be nilpotent if it is nilpotent as an element of \( \mathfrak{gl}(n, k) \).

One can show that this definition is equivalent to the one given above.

b) One can define an element \( x \) of \( \mathfrak{g} \) to be semi-simple if \( x \) is contained in the Lie algebra of a torus of \( G \). The remarks made under a) hold too in that case.

It can be proved that if \( G \) is a connected linear algebraic group over \( k \) (algebraically closed) any element \( x \) of the Lie algebra \( \mathfrak{g} \) of \( G \) can be written in the form \( x = x_s + x_n \), where \( x_s \) (\( x_n \)) is a semi-simple (nilpotent) element of \( \mathfrak{g} \), such that \( [x_s, x_n] = 0 \). Moreover such a decomposition is unique (1).

c) In the case that the characteristic of \( k \) is 0, the statements about nilpotent elements of \( \mathfrak{g} \) to be given below can be derived easily from the corresponding ones about unipotent elements in \( G \) (e.g. using an "exponential mapping ").

(5.3) Lemma. — Let \( S \) be the set of simple roots of \( R \), defining the ordering of \( R \). Let \( x = \sum_{r > 0} \xi_r e_r \) be an element of \( \mathfrak{u} \) such that \( \xi_r = 0 \) if \( r \in S \). Then there is exactly one Borel subgroup of \( G \) whose Lie algebra contains \( x \), viz. \( B \). \( G_x \) is the direct product of the center of \( G \) and of \( U_x \), the centralizer of \( x \) in \( U \).

The proof of this is completely analogous to that of (4.3), so we leave it to the reader.

Let \( X \) denote the set of all nilpotent elements of \( \mathfrak{g} \), let \( l \) be the rank of \( G \).

(5.4) Proposition. — \( X \) is an irreducible Zariski-closed subset of the affine space \( W(\mathfrak{g}) \) determined by \( \mathfrak{g} \), whose dimension is \( \dim G - l \).

This is proved like (4.4), using (5.3).

(5.5) Remark. — By a similar argument one derives from (5.3) the following result of Grothendieck: \( \mathfrak{g} \) is the union of the Lie algebras of its Borel subgroups ([15], exposé XIV, th. 4.11, the proof given there is different).

(5.6) Proposition. — Let \( x \) be a nilpotent element of \( \mathfrak{g} \), then \( \dim G_x \geq l \).

Because the orbit of \( x \) under the adjoint action of \( G \) is contained in \( X \), we have \( \dim G/G_x \leq \dim X \), which implies (5.6).

Remark. — (5.6) is true for all \( x \in \mathfrak{g} \).

(5.7) We now define \( x \in \mathfrak{g} \) to be regular if \( \dim G_x = l \) and smoothly regular if \( \dim \mathfrak{g}_x = l \) \(^{(1)} \). Since \( \dim G_x \leq \dim \mathfrak{g}_x \) it follows from (5.6) that a smoothly regular nilpotent element is regular (it will follow from (5.9) that the converse is not true).

(5.8) Lemma. — Suppose that \( \mathfrak{g} \) contains regular nilpotent elements. Then any \( x \in \mathfrak{g} \) with the property of (5.3) is regular.

The proof is like that of (4.7).

(5.9) Theorem. — a) Smoothly regular nilpotent elements exist in \( \mathfrak{g} \) if and only if the characteristic of \( k \) is either 0 or a good prime for \( G \), which does not divide the order of the fundamental group of \( R \).

b) If \( p \) is either 0 or a good prime for \( G \) then regular nilpotent elements exist in \( \mathfrak{g} \), the centralizer \( G_x \) of a regular nilpotent element \( x \) is then the direct product of the center of \( G \) and a connected unipotent subgroup of \( G \).

c) The regular nilpotent elements of \( \mathfrak{g} \) form one orbit of \( G \) under adjoint action.

From (5.8) it follows that if \( \mathfrak{g} \) contains regular nilpotent elements, then \( x = \sum_{\alpha \in \Delta} \epsilon^\alpha \) is one (\( \Delta \) is the set of simple roots). So in order to prove a) it suffices to investigate when \( \dim \mathfrak{g}_x = l \).

This one can read off from (2.5) and (2.6) (using (2.11)).

b) is proved in the same way as (4.11), the details may be left to the reader. The conjugacy statement of c) is proved as the corresponding statement of (4.7).

(5.10) Remark. — One can ask whether (4.12) has a counterpart for \( \mathfrak{g} \). The proof of (4.12) depended on Steinberg’s result that regular unipotent elements exist in all characteristics. The author does not know whether the corresponding result is true for Lie algebras.

Mathematisch Instituut der Rijksuniversiteit, Utrecht.

\(^{(1)}\) The name smoothly regular has been chosen because the centralizer of a regular element \( x \) in the sense of group schemes is smooth over \( k \) if and only if \( x \) is smoothly regular.

APPENDIX

We give here tables for the positive roots of the root-systems of type $\mathbf{E}_6$, $\mathbf{E}_7$, $\mathbf{E}_8$, $\mathbf{F}_4$, when expressed in the simple roots. Description of these root-systems are given in (2.9). We use an evident abbreviation in the tables: for example, in the case $\mathbf{E}_6$, 012211 denotes the root $r_2 + 2r_3 + r_5 + r_6$, where the $r_i$ are the simple roots given in (2.9).
