APPENDIX : AN EXAMPLE OF A THICK WALL

by NICOLAS RESSAYRE

Among quotients associated to distinct G -linearized line bundles, those corresponding to chambers have a very good property: the fibers are orbits. Theorem 4.2.7 shows that between two relevant chambers the quotient is changed by a transformation similar to a Mori flip. Moreover, if G is a torus, then two quotients corresponding to chambers are linked by a finite sequence of such transformations. In this appendix, we show by an example that this can fail for arbitrary reductive group G . For this, we produce a linear action of G on a projective space, which admits a proper wall of codimension zero.

Let us fix some notation. We consider the connected reductive group $G = \mathbf{C}^* \times \mathrm{SL}(2, \mathbf{C})$. Let χ_0 be the character of G defined by $\chi_0(t, g) = t$. Then χ_0 generates the character group of G . If T_1 is the maximal torus of $\mathrm{SL}(2, \mathbf{C})$ consisting in diagonal matrices, then $T = \mathbf{C}^* \times T_1$ is a maximal torus of G . Its character group is freely generated by χ_0 , and χ_1 defined by the following formula:

$$\chi_1 \left(t, \begin{pmatrix} u & 0 \\ 0 & u^{-1} \end{pmatrix} \right) = u, \quad t, u \in \mathbf{C}^*.$$

Let $W = \mathbf{C}^2$, $V = \mathbf{C}^5$. Let us choose an isomorphism $V \simeq \mathbf{C} \oplus \mathbf{C} \oplus W \oplus W \oplus W$. An element of V is thus represented by a 5-tuple $(x_-, x_0, v_-, v_0, v_+)$ where $x_-, x_0 \in \mathbf{C}$ and $v_-, v_0, v_+ \in W$. We define an action of G on V by the following formula:

$$(1) \quad (t, g) \star (x_-, x_0, v_-, v_0, v_+) = (t^{-2} x_-, x_0, t^{-8} g \cdot v_-, g \cdot v_0, t^2 g \cdot v_+),$$

where \cdot is the canonical action of $\mathrm{SL}(2, \mathbf{C})$ on W . From now on, we use the notation of Section 1.1.5.

We represent the set of weights of the action of T on V by Figure 1. The coordinates in the basis (χ_0, χ_1) of these weights are denoted by (a, b) in the figure. In addition, the convex hulls of some parts of $\mathrm{st}(V)$ are drawn with thick lines.

FIG. 1. — State of V

Formula (1) defines an action of G on $X = \mathbf{P}(V)$ and a G -linearization on $\mathcal{O}_X(1)$ as well; we denote by \mathcal{L} this G -linearized line bundle. According to Section 1.1.5, for \mathcal{L} , a point $x \in X$ is:

- semi-stable if and only if for all $g \in G$, the origin belongs to the set $\text{Conv}(\text{st}_V(g \cdot x))$;
- stable if and only if for all $g \in G$, the origin belongs to the interior of $\text{Conv}(\text{st}_V(g \cdot x))$;
- unstable if and only if there exists $g \in G$ such that the origin does not belong to $\text{Conv}(\text{st}_V(g \cdot x))$.

Now we want to vary the ample G -linearized line bundle on X . We also denote by χ_0 the trivial line bundle over X where G acts on the fibers by χ_0 . Since the group $\text{NS}(X)$ is isomorphic to \mathbf{Z} , by [KKV] each G -linearized line bundle on X is isomorphic to $\mathcal{L}^{\otimes n} \otimes m\chi_0$ for some $(m, n) \in \mathbf{Z}^2$. It follows that the group $\text{NS}^G(X)$ is isomorphic to \mathbf{Z}^2 . From now on, we identify $\text{NS}^G(X)$ with \mathbf{Z}^2 , and so $\text{NS}^G(X)_{\mathbf{R}}$ with \mathbf{R}^2 . Note that the line bundle corresponding to $(m, n) \in \mathbf{Z}^2$ is ample if and only if n is positive. Since two ample G -linearized line bundles on the same half-line from the origin are GIT-equivalent, we can restrict our study to the points of $\text{NS}^G(X)_{\mathbf{R}}$ of the form $(r, 1)$ with $r \in \mathbf{R}$. We call the set of these points *the horizontal line* and r the *abscissa* of the point $(r, 1)$. We use these conventions in Figure 2.

Let $r \in \mathbf{Q}$. There exists a power, say $\mathcal{L}^{\otimes n} \otimes m\chi_0$ (with $m = nr \in \mathbf{Z}$), of $\mathcal{L} \otimes r\chi_0$ which is the restriction (as a G -line bundle) of $\mathcal{O}(1)$ for an embedding of X into a G -module. The sets $\text{st}(x)$ corresponding to this embedding are obtained from $\text{st}_V(x)$ by applying a dilation of factor n followed by a translation of vector $(m, 0)$. So to study the stability for $\mathcal{L} \otimes r\chi_0$, we can move the origin along the horizontal line in Figure 1 by $-r$ and keep the weights of the action of V . Finally the stability for $\mathcal{L} \otimes r\chi_0$ of a point $x \in X$ depends on the relative position of the point $(-r, 0)$ and the convex hulls in $\mathcal{X}(T) \otimes \mathbf{R}$ of the sets $\text{st}_V(g \cdot x)$ with $g \in G$.

From now on, we denote by (e_1, e_2) the canonical basis of W . Let $x \in X$ and let $\tilde{x} = (x_-, x_0, v_-, v_0, v_+)$ be a representative of x in V . There exists $g \in \text{SL}(2, \mathbf{C})$ such that $g \cdot v_-$ is proportional to e_1 . But now, if $r > 4$ the point $(-r, 0)$ does not belong to the convex hull of $\text{st}(g \cdot x)$ and x is not semi-stable for $\mathcal{L} \otimes r\chi_0$. So if $r > 4$, $X^{\text{ss}}(\mathcal{L} \otimes r\chi_0)$ is empty. Analogously, we prove that if $r < -1$ then $\mathcal{L} \otimes r\chi_0$ is not effective.

Moreover, the “origins” of the form $(-r, 0)$ in Figure 1 which correspond to the intersection of the horizontal line and a wall belong to the boundary of a set $\text{conv}(\text{st}(x))$ for some $x \in X$. So the abscissa of the intersection of a wall and the horizontal line is $r = 4, r = 3, r = 2, r = 0, r = -1$ or the segment $0 \leq r \leq 2$.

Let $x = [0 : 0 : e_1 : e_2 : 0]$. There are seven distinct sets of the form $\text{st}(g \cdot x)$: two segments, four triangles and one rectangle. The point $(-4, 0)$ is either on the boundary or in the interior of these convex sets. So, $r = 4$ is the abscissa of the wall $H(x)$. In the same way, we show that $r = 3$ is the wall $H([0 : 0 : e_1 : 0 : e_2])$ and $r = -1$ is the wall $H([0 : 0 : 0 : e_1 : e_2])$.

Obviously, the walls $H([1 : 0 : 0 : 0 : 0])$ and $H([0 : 1 : 0 : 0 : 0])$ have $r = 2$ and $r = 0$ as their abscissa. Moreover, the intersection of the horizontal line and the wall $H([1 : 1 : 0 : 0 : 0])$ is the interval $0 \leq r \leq 2$.

So we obtain six walls, three chambers and six cells in the G -ample cone (see Figure 2). The cone $\mathcal{C}^G(X)$ is partitioned into nine GIT-classes.

FIG. 2. — The G -ample cone

Theorem 4.2.7 compares quotients corresponding to two chambers C^+ and C^- relevant to a cell F . The starting point is that the set $X^{\text{ss}}(F)$ contains both $X^s(C^+)$ and $X^s(C^-)$, and so defines two morphisms:

$$X^{\text{ss}}(C^+) // G \xrightarrow{f_+} X^{\text{ss}}(F) // G \xleftarrow{f_-} X^{\text{ss}}(C^-) // G.$$

In the G -ample cone, the property $X^{\text{ss}}(F) \supset X^{\text{ss}}(C)$ means that F intersects the closure of C . Moreover, if we want to have $X^s(F) = X^s(C^+) \cap X^s(C^-)$ it is natural to assume that C^+ and C^- are relevant to F . This explains why Theorem 4.2.7 concerns two relevant chambers to a face.

On the other hand, if there is no codimension zero wall, then any two chambers can be joined by a chain of relevant chambers. So quotients corresponding to two

arbitrary chambers are related by a sequence of birational transformations corresponding to relevant chambers.

Back to the example, if we want to relate the quotients associated to C^1 and C^2 , we must look at the sequence of transformations

$$\begin{array}{ccccc}
 X^{\text{ss}}(C^1)//G & & X^{\text{ss}}(\mathcal{L} \otimes \chi_0)//G & & X^{\text{ss}}(C^2)//G \\
 \searrow & & \swarrow & & \swarrow \\
 & & X^{\text{ss}}(\mathcal{L})//G & & X^{\text{ss}}(\mathcal{L} \otimes 2\chi_0)//G
 \end{array}$$

and so, we obtain $X^{\text{ss}}(\mathcal{L} \otimes \chi_0)//G$ as a natural intervening quotient between $X^{\text{ss}}(C^1)//G$ and $X^{\text{ss}}(C^2)//G$.
