# ISOTROPY OF QUADRATIC FORMS OVER FUNCTION FIELDS OF p-ADIC CURVES 

by R. PARIMALA and V. SURESH

## INTRODUGTION

Let $k$ be a field of characteristic not equal to 2 . We recall the notion of the $u$-invariant $u(k)$ of $k$.

$$
u(k)=\sup \{\text { dimension of } q \mid q \text { an anisotropic quadratic form over } k\}
$$

It is a longstanding question whether the finiteness of $u(k)$ implies the finiteness of $u(k(t))$. This was open even in the case $k$ is a $p$-adic field. Recently, by using a theorem of Saltman ([S], 3.4, [S1], [HV], 2.5) on bounding the index of central simple algebras over the function field $k(\mathrm{X})$ in one variable over a non-dyadic $p$-adic field by the square of the exponent, Hoffmann - Van Geel ([HV], 3.7) and independently Merkurjev ([M2]) proved the finiteness of the $u$-invariant of $k(\mathrm{X})$. Hoffmann and Van Geel ([HV], 3.7) proved that $u(k(\mathrm{X})) \leqslant 22$. In this paper, we follow the techniques of Saltman to prove that the $u$-invariant of $k(\mathbf{X})$ is bounded by 10 . We remark that conjecturally $u(k(\mathrm{X}))=8$. Recall that if F is a finite field, $k=\mathrm{F}((t))$ is $\mathrm{C}_{2}$ and if X is an irreducible curve over $k$, then $k(\mathrm{X})$ is a $\mathrm{C}_{3}$ field ([Gre], $\mathrm{p} 36, \mathrm{p} 22$ ) and hence $u(k(\mathrm{X}))=8$.

The main step of the proof is to kill any element in $\mathrm{H}^{3}(k(\mathrm{X}), \mathbf{Z} / 2)$ in a quadratic extension of $k(\mathbf{X})$ (3.8). This is done by killing the ramification of any element of $\mathrm{H}^{3}(k(\mathrm{X}), \mathbf{Z} / 2)$ on a regular proper model $\mathscr{K}$ of a quadratic extension L of $k(\mathrm{X})$ and using a theorem of Kato ( $[\mathrm{K}], 5.2$ ) that the unramified cohomology group $\mathrm{H}_{\mathrm{nr}}^{3}(\mathrm{~L} / \mathscr{B}, \mathbf{Z} / 2)=0$. This shows that every element $\alpha$ in $\mathrm{H}^{3}(k(\mathbf{X}), \mathbf{Z} / 2)$ is of the form $(f) \cup \beta$, with $(f) \in \mathrm{H}^{1}(k(\mathbf{X}), \mathbf{Z} / 2)=k(\mathbf{X})^{*} / k(\mathbf{X})^{* 2}$ and $\beta \in \mathrm{H}^{2}(k(\mathbf{X}), \mathbf{Z} / 2)$. In view of a theorem of Saltman (cf. 2.2), $\beta$ and hence $\alpha$, is a sum of two symbols. A subtler choice of a biquadratic extension (2.1) which splits $\beta \in \mathrm{H}^{2}(k(\mathrm{X}), \mathbf{Z} / 2)$ leads to the fact that every element in $\mathrm{H}^{3}(k(\mathbf{X}), \mathbf{Z} / 2)$ is a symbol $(f) \cup(g) \cup(h)$. In fact we also prove (3.9) that given $\alpha_{i} \in \mathbf{H}^{3}(k(\mathbf{X}), \mathbf{Z} / 2), 1 \leqslant i \leqslant n$, there exist $f, g, h_{i} \in k(\mathbf{X})^{*}$ such that $\alpha_{i}=(f) \cup(g) \cup\left(h_{i}\right)$. This is a local two-dimensional analogue of a result of Tate for number fields ([T], 5.2).

Using methods of Hoffmann and Van Geel ([HV]) and the fact that every element in $\mathrm{H}^{3}(k(\mathbf{X}), \mathbf{Z} / 2)$ is a symbol, one can deduce that $u(k(\mathbf{X})) \leqslant 12$ (4.2). One shows further that given $\alpha \in \mathrm{H}^{3}(k(\mathbf{X}), \mathbf{Z} / 2)$, a suitable choice of a quadratic extension $\mathrm{L}=k(\mathrm{X})(\sqrt{f})$ which splits $\alpha$ can be made so that $f$ is a value of a given binary quadratic form (4.4). This leads to $u(k(\mathrm{X})) \leqslant 10$ (4.5).

Let $k$ be a $p$-adic field and C a smooth, projective, geometrically integral curve over $k$. Let $\pi: \mathrm{X} \rightarrow \mathrm{C}$ be an admissible quadric fibration (cf. [CSk]) and $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})$ the kernel of the induced homomorphism $\pi_{*}: \mathrm{CH}_{0}(\mathrm{X}) \rightarrow \mathrm{CH}_{0}(\mathrm{C})$, where $\mathrm{CH}_{0}$ denotes the group of zero-cycles modulo rational equivalence. In ([CSk]), Colliot-Thelene and Skorobogatov posed the question whether $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})$ is zero if $\operatorname{dim}(\mathrm{X}) \geqslant 4$. In ([HV], 4.2), Hoffmann and Van Geel showed that if $k$ is non-dyadic and $\operatorname{dim} X \geqslant 6$, then, $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})=0$. They further proved that if every element in $\mathrm{H}^{3}(k(\mathrm{X}), \mathbf{Z} / 2)$ is a symbol and $\operatorname{dim}(\mathrm{X}) \geqslant 4$, then $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})=0([\mathrm{HV}], 4.4)$. Thus, as a consequence of our result, it follows that if $\operatorname{dim}(\mathrm{X}) \geqslant 4$, then $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})=0$ (5.2), answering the above question of Colliot-Thélène and Skorobogatov in the affirmative.

In ([Se], §8.3), Serre raised the question whether for a $p$-adic field $k$, every element in $\mathrm{H}^{3}(k(t), \mathbf{Z} / 2)$ is a symbol. In this were true, he has the following explicit description of the set of isomorphism classes of Cayley algebras over $k(t)$ as the set

$$
\mathbf{C}(\mathbf{P})=\left\{f . \mathbf{P} \rightarrow \mathbf{Z} / 2 \mid \operatorname{Supp}(f) \text { finite and } \sum_{x \in \mathbf{P}} f(x)=0\right\}
$$

where $\mathbf{P}$ denotes the set of closed points of $\mathbf{P}_{k}^{1}$. Using our theorem and a result of Kato ( K$]$ ), we give a description (6.3), following Serre's method, of the set of isomorphism classes of Cayley algebras over $k(\mathrm{X})$, where X is a smooth, irreducible curve over a non-dyadic $p$-adic field, which reduces to that of Serre in the case $\mathbf{X}=\mathbf{P}_{k}^{1}$.

We thank J.-L. Colliot-Thélène for various helpful discussions during the preparation of this paper. We thank S. Bloch, D. Hoffmann and Van Geel for their keen interest in this work. We thank J.-P Serre for bringing to our notice the question discussed in §6. We thank the organisers of the "Arithmetic Geometry" programme at the Isaac Newton Institute, University of Cambridge, for inviting us to participate in the programme, and we acknowledge with pleasure the local hospitality at the Isaac Newton Institute while this paper was under preparation.

## 1. Some Preliminaries

We recall (cf. [Sc]) some basic definitions and facts about quadratic forms and (cf. [C]) some results on Galois cohomology and unramified cohomology. Let F be a field of characteristic not equal to 2. By a quadratic form over F we mean a pair $(\mathrm{V}, q)$, where V is a finite dimensional vector space, $q: \mathrm{V} \rightarrow \mathrm{F}$ is a map such that $q(\lambda v)=\lambda^{2} q(v)$, for $\lambda \in \mathrm{F}, v \in \mathrm{~V}$ and the map $b_{q}: \mathrm{V} \times \mathrm{V} \rightarrow \mathrm{F}$ given by $b_{q}(v, w)=q(v+w)-q(v)-q(w)$ is a non-singular bilinear form. We shall abbreviate $(\mathrm{V}, q)$ by $q$. Let $q$ be a quadratic form over F . The rank of $q$, denoted by $\mathrm{rk}(q)$, is defined as the dimension of V over F. We say that a quadratic form $q$ over F is isotropic if there exists $v \in \mathrm{~V}, v \neq 0$, such that $q(v)=0$; otherwise $q$ is called anisotropic. The $u$-invariant of F , denoted by $u(\mathrm{~F})$, is
defined as

$$
u(\mathbf{F})=\sup \{\operatorname{rk}(q) \mid q \text { an anisotropic quadratic form over } \mathbf{F}\}
$$

Let $q$ be a quadratic form over F . Since $\operatorname{char}(\mathrm{F}) \neq 2, q$ is isometric to a diagonal form $<a_{1}, \cdots, a_{n}>$, for some $a_{i} \in \mathrm{~F}^{*}$. A quadratic form is isotropic if and only if $q \simeq<1,-1>\perp q^{\prime}$ for some quadratic form $q^{\prime}$ over F. A quadratic form $q$ is said to be hyperbolic if $q \simeq<1,-1>\perp \cdots \perp<1,-1>$. Let $W(F)$ be the Witt group of quadratic forms over $F$. Note that every element in $W(F)$ is represented by an anisotropic quadratic form over F. A quadratic form $q$ represents 0 in $W(F)$ if and only if $q$ is hyperbolic. Tensor product of quadratic forms makes $\mathrm{W}(\mathrm{F})$ into a ring. Let $\mathrm{I}(\mathrm{F})$ be the ideal of $\mathrm{W}(\mathrm{F})$ consisting of even rank forms. For $n \geqslant 1$, let $\mathrm{I}^{n}(\mathrm{~F})$ denote the $n^{\text {th }}$ power of $\mathrm{I}(\mathrm{F})$. The abelian group $\mathrm{I}^{n}(\mathrm{~F})$ is generated by quadratic forms of the type $<1, a_{1}>\otimes \cdots \otimes<1, a_{n}>$, with $a_{i} \in \mathrm{~F}^{*}$. A quadratic form of the type $<1, a_{1}>\otimes \cdots \otimes<1, a_{n}>$ is called an $n$-fold Pfister form. Let $\mathrm{P}_{n}(\mathrm{~F})$ denote the set of $n$-fold Pfister forms over F.

The rank induces an isomorphism $\mathrm{rk}: \mathrm{W}(\mathbf{F}) / \mathbf{I}(\mathbf{F}) \simeq \mathbf{Z} / 2$. For a quadratic form over F, let $d(q)$ be the discriminant of $q$ and $c(q)$ the Clifford invariant of $q$. Then the discriminant induces an isomorphism $d: \mathrm{I}(\mathrm{F}) / \mathrm{I}^{2}(\mathrm{~F}) \rightarrow \mathrm{F}^{*} / \mathrm{F}^{* 2}$. A celebrated theorem of Merkurjev ([M1]) asserts that $c$ induces an isomorphism

$$
\frac{\mathrm{I}^{2}(\mathbf{F})}{\mathrm{I}^{3}(\mathbf{F})} \stackrel{\sim}{\rightarrow} \mathrm{H}^{2}(\mathbf{F}, \mathbf{Z} / 2)
$$

where for any $n \geqslant 0, H^{n}(\mathbf{F}, \mathbf{Z} / 2)$ denotes the $n^{\text {th }}$ Galois cohomology group $\mathrm{H}^{n}\left(\operatorname{Gal}\left(\mathrm{~F}_{s} / \mathbf{F}\right), \mathbf{Z} / 2\right), \mathrm{F}_{s}$ denoting the separable closure of F . For $a \in \mathbf{F}^{*}$, let (a) denote the class in $\mathbf{H}^{1}(\mathbf{F}, \mathbf{Z} / 2)=\mathbf{F}^{*} / \mathrm{F}^{* 2}$. For $a_{1}, \cdots, a_{n} \in \mathrm{~F}^{*}$, let $\left(a_{1}\right) \cdot \cdots \cdot\left(a_{n}\right)$ denote the element $\left(a_{1}\right) \cup \cdots \cup\left(a_{n}\right) \in \mathrm{H}^{n}(\mathbf{F}, \mathbf{Z} / 2)$. Let $n \geqslant 1$. For $a_{1}, \cdots, a_{n} \in \mathbf{F}^{*}$, let

$$
e_{n}: \mathrm{P}_{n}(\mathbf{F}) \rightarrow \mathrm{H}^{n}(\mathbf{F}, \mathbf{Z} / 2)
$$

be defined by $e_{n}\left(<1,-a_{1}>\otimes \cdots \otimes<1,-a_{n}>\right)=\left(a_{1}\right) \cdots\left(a_{n}\right) \in \mathbf{H}^{n}(\mathbf{F}, \mathbf{Z} / 2)$. Then $e_{1}$ is the discriminant and $e_{2}$ is the Clifford invariant. Suppose that the 2 -cohomological dimension $\mathrm{cd}_{2}(\mathrm{~F})$ of F is at most 3. Then by a theorem of Arason, Elman and Jacob ([AEJ], Corollary 4 and Theorem 2), $\mathrm{I}^{4}(\mathrm{~F})=0$ and

$$
e_{3}: \mathrm{I}^{3}(\mathbf{F}) \rightarrow \mathrm{H}^{3}(\mathbf{F}, \mathbf{Z} / 2)
$$

is an isomorphism.
Let R be a discrete valuation ring, F its quotient field and $\mathrm{\kappa}$ its residue field. Assume that the characteristic of $\kappa$ is not equal to 2 . For $q \geqslant 1$, let

$$
\partial_{\mathrm{R}}: \mathbf{H}^{q}(\mathbf{F}, \mathbf{Z} / 2) \rightarrow \mathbf{H}^{q-1}(\boldsymbol{\kappa}, \mathbf{Z} / 2)
$$

be the residue homomorphism defined with respect to $\mathbf{R}$. If P is the maximal ideal of R , then sometimes we denote $\partial_{\mathrm{R}}$ by $\partial_{\mathrm{P}}$. For $u_{i}$ units in $\mathrm{R}, 1 \leqslant i \leqslant q-1$ and $\pi$ a parameter in R, we have $\partial_{\mathrm{R}}\left(\left(u_{1}\right) \cdots\left(u_{q-1}\right) \cdot(\pi)\right)=\left(\bar{u}_{1}\right) \cdots\left(\bar{u}_{q-1}\right)$, where bar denotes the image in $\kappa$.

Let $\mathscr{X}$ be a regular integral scheme of dimension $n$ and F its function field. For $i \geqslant 0$, let $\mathscr{S}^{i}$ denote the set of points of $\mathscr{B}$ of codimension $i$. For any $x \in \mathscr{X}$, let $\kappa(x)$ denote the residue field at $x$. Assume that the characteristic of $\mathrm{K}(x)$ is not equal to 2, for any $x \in \mathscr{C}$. For $x \in \mathscr{K}^{1}$, let $\mathscr{O}_{\mathscr{K}, x}$ denote the discrete valuation ring at $x$ and $\partial_{x}: \mathrm{H}^{q}(\mathbf{F}, \mathbf{Z} / 2) \rightarrow \mathrm{H}^{q-1}(\mathbf{\kappa}(x), \mathbf{Z} / 2)$ the residue homomorphism defined with respect to $\mathscr{O}_{\mathscr{C}, x}$. Let

$$
\mathbf{H}_{\mathrm{nr}}^{q}(\mathbf{F} / \mathscr{X}, \mathbf{Z} / 2)=\operatorname{ker}\left(\mathbf{H}^{q}(\mathbf{F}, \mathbf{Z} / 2) \xrightarrow{\partial=\left(\partial_{x}\right)} \bigoplus_{x \in \mathscr{R}^{1}} \mathbf{H}^{q-1}(\mathbf{\kappa}(x), \mathbf{Z} / 2)\right) .
$$

An element $\alpha \in \mathbf{H}^{q}(\mathbf{F}, \mathbf{Z} / 2)$ is called unramified at a point $x \in \mathscr{X}^{1}$, if $\partial_{x}(\boldsymbol{\alpha})=0$; otherwise it is called ramified at $x$. We say that $\alpha \in \mathrm{H}^{q}(\mathbf{F}, \mathbf{Z} / 2)$ is unramified on $\mathscr{X}$ if it is unramified at all points of $\mathscr{S}^{1}$, i.e., $\alpha \in \mathrm{H}_{\mathrm{nr}}^{q}(\mathbf{F} / \mathscr{X}, \mathbf{Z} / 2)$. We define the ramification divisor

$$
\operatorname{ram}_{\mathscr{X}}(\boldsymbol{\alpha})=\sum_{\partial_{X}(\alpha) \neq 0} x .
$$

For $f \in \mathrm{~F}^{*}$, we denote by $\operatorname{Supp}_{\mathscr{C}}(f)$ the support of the principal divisor $\operatorname{div}_{\mathscr{\mathscr { C }}}(f)$.
Let $k$ be a $p$-adic field, $p \neq 2$. Let X be a smooth, projective, integral curve over $k$ and $\mathbf{K}=k(\mathbf{X})$ the function field of $\mathbf{X}$. Let $\mathscr{O}_{k}$ be the ring of integers of $k$. For $\alpha_{i} \in \mathrm{H}^{q}(\mathbf{K}, \mathbf{Z} / 2)$ and $f_{j} \in \mathbf{K}^{*}, 1 \leqslant i \leqslant n, l \leqslant j \leqslant m$, by a result of Lipman on the resolution of singularities (cf. [S], Proof of 2.1), there exists a regular, projective model $\mathscr{E}$ of X over $\mathscr{O}_{k}$ and two regular curves C and E on $\mathscr{\mathscr { C }}$ with only normal crossings (i.e., for every $x \in \mathrm{C} \cap \mathrm{E}$, the maximal ideal of the local ring $\mathscr{O}_{\mathscr{C}, x}$ is generated by local equations of C and E at $x$ ), such that

$$
\cup_{1 \leqslant i \leqslant n} \operatorname{Supp}\left(\operatorname{ram}_{\mathscr{X}}\left(\alpha_{i}\right)\right) \cup \cup_{1 \leqslant j \leqslant m} \operatorname{Supp}_{\mathscr{O}}\left(f_{j}\right) \subset \operatorname{Supp}(\mathrm{C}+\mathrm{E}) .
$$

We use this result throughout this paper without further reference.
Let F be a field of characteristic not equal to 2 and L a field extension of F . For any $\alpha \in \mathrm{H}^{q}(\mathbf{F}, \mathbf{Z} / 2)$, the image of $\alpha$ in $\mathrm{H}^{q}(\mathrm{~L}, \mathbf{Z} / 2)$ under the restriction map is denoted by $\alpha_{L}$. Let $\mathscr{C}$ be a scheme and $x \in \mathscr{B}$. Let $\mathscr{O}_{\mathscr{C}, x}$ be the local ring at $x$. For any $f \in \mathscr{O}_{\mathscr{X}, x}$, the image of $f$ in $\kappa(x)$ is denoted by $f(x)$. For any ring A, let $\mathrm{A}^{*}$ denote the group of units in A . Let $\mathrm{A} \subset \mathrm{B}$ be local rings with maximal ideals $m_{\mathrm{A}}$ and $m_{\mathrm{B}}$ respectively. We say that B dominates A if $m_{\mathrm{A}} \subset m_{\mathrm{B}}$. In the rest of the paper, we assume that 2 is invertible in all the rings concerned.

## 2. Cohomology in degree 2

Let $k$ be a non-dyadic $p$-adic field and $\mathscr{O}_{k}$ the ring of integers in $k$. Let X be a smooth, projective, irreducible curve over $k$ and $\mathrm{K}=k(\mathbf{X})$ the function field of $\mathbf{X}$ over $k$.

Proposition 2.1. - Let $k, \mathrm{X}$ and K be as above. Let $\boldsymbol{\alpha}_{i} \in \mathrm{H}^{2}(\mathrm{~K}, \mathbf{Z} / 2), 1 \leqslant i \leqslant n$. Let $\mathscr{X}$ be a regular, projective model of X over $\mathscr{O}_{k}$ such that

$$
\bigcup_{i=1}^{n} \operatorname{Supp}\left(\operatorname{ram}_{\mathscr{X}}\left(\boldsymbol{\alpha}_{i}\right)\right) \subset \operatorname{Supp}(\mathrm{C}+\mathrm{E}),
$$

where C and E are regular curves on $\mathscr{B}$ having only normal crossings. Suppose there exists $f \in \mathrm{~K}^{*}$ such that

$$
\operatorname{div}_{\mathscr{O}}(f)=\mathrm{C}+\mathbf{E}+\mathbf{F},
$$

where F is a divisor on $\mathscr{B}$ whose support does not contain any point of $\mathrm{C} \cap \mathrm{E}$ and no component of C or E is contained in F . Let T be the finite set of closed points consisting of $\mathrm{C} \cap \mathrm{E}, \mathrm{C} \cap \mathrm{F}, \mathrm{E} \cap \mathrm{F}$. Let B be the semi-local ring at T . Let $h \in \mathrm{~B}, h \neq 0$, be such that $\operatorname{Supp}_{\mathrm{Spec}(\mathrm{B})}(h) \subset \operatorname{Supp}(\mathrm{C}+\mathrm{E})$ and $h$ is square free in $B$. Suppose $x \in \mathrm{C} \cap \mathrm{E}$ is a closed point. Let $\pi_{x}$ and $\delta_{x}$ be local equations at $x$ for $C$ and $E$ respectively. We write $h=\pi_{x}^{\varepsilon_{1}} \delta_{x}^{\varepsilon_{2}} w_{x}$ and $f=\pi_{x} \delta_{x} w_{x}^{\prime}$, where $w_{x}, w_{x}^{\prime}$ are units at $x$ and $\varepsilon_{1}, \varepsilon_{2} \in\{0,1\}$. Suppose there exists an element $h_{1} \in \mathrm{~B}^{*}$ such that for $x \in \mathrm{~T}$,
(i) if $h(x) \neq 0$, then $\left(h h_{1}\right)(x)$ is not a square in $\mathrm{K}(x)$.
(ii) if $h(x)=0$ and either $x \in \mathrm{C} \cap \mathrm{F}$ or $x \in \mathrm{E} \cap \mathrm{F}$, then $h_{1}$ is a unit at $x$.
(iii) if $h(x)=0$ and $x \in \mathrm{C} \cap \mathrm{E}$, then $\left(w_{x} w_{x}^{\prime} h_{1}\right)(x)$ is not a square in $\mathrm{K}(x)$.

Then the image of $\boldsymbol{\alpha}_{i}$ in $\mathbf{H}^{2}\left(\mathbf{K}\left(\sqrt{f}, \sqrt{h h_{1}}\right), \mu_{2}\right)$ is zero, for $1 \leqslant i \leqslant n$.
Proof. - Let $\mathrm{L}=\mathrm{K}\left(\sqrt{f}, \sqrt{h h_{1}}\right)$ and S be a discrete valuation ring, containing $\mathscr{O}_{k}$, with quotient field L . Since $\mathscr{\mathscr { C }}$ is projective over $\mathscr{O}_{k}$, there exists a point $x \in \mathscr{B}$ of codimension 1 or 2 such that S dominates the local ring $\mathrm{A}=\mathscr{O}_{\mathscr{C}, x}$. We show that, for $1 \leqslant i \leqslant n,\left(\boldsymbol{\alpha}_{i}\right) \mathrm{L}$ is unramified at S. Fix $i, 1 \leqslant i \leqslant n$ and let $\boldsymbol{\alpha}=\boldsymbol{\alpha}_{i}$.

Suppose that $x \notin \mathrm{C} \cup \mathrm{E}$. Then $\alpha$ is unramified on A and hence unramified over $\mathrm{S}([\mathrm{S}], 1.4)$. Assume that $x \in \mathrm{C} \cup \mathrm{E}$.

Suppose that $\operatorname{dim}(\mathbf{A})=1$. Then $f$ is a parameter at $x$ and hence S is ramified over A. Therefore $\alpha$ is unramified on S .

Suppose that $\operatorname{dim}(\mathrm{A})=2$. Let $m_{\mathrm{S}}$ be the maximal ideal of S and $\mathrm{v}_{\mathrm{S}}$ the valuation of S . We show that $\partial_{\mathrm{S}}\left(\boldsymbol{\alpha}_{\mathrm{L}}\right)=0$.

Suppose that $x \in \mathbf{C} \backslash(\mathbf{E} \cup f)$ (resp. $x \in \mathbf{E} \backslash(\mathbf{C} \cup f))$. Then $f$ is a local equation for C (resp. E ) at $x$ and $\alpha$ can be ramified only at $(f)$ in $\mathbf{A}$. By ([S], 1.2), we have
$\alpha=\alpha^{\prime}+(u) \cdot(f)$, where $\alpha^{\prime}$ is unramified on A and $u \in \mathrm{~A}^{*}$. Since $(u) \cdot(f)_{\mathrm{L}}=(u) \cdot(1)=0$, $\alpha_{\mathrm{L}}=\alpha_{\mathrm{L}}^{\prime}$ is unramified at S .

Suppose that $x \in \mathrm{C} \cap \mathrm{F}$. Then $x \notin \mathrm{E}$ and hence, by ([S], 1.2), $\alpha=\alpha^{\prime}+(u) \cdot\left(\pi_{x}\right)$, where $\alpha^{\prime}$ is unramified on A, $u \in \mathrm{~A}^{*}$. Suppose further that $h(x) \neq 0$. Then $\left(h h_{1}\right)(x)$ is not a square in $\kappa(x)$. We have $\partial_{\mathrm{S}}\left((u) \cdot\left(\pi_{x}\right)\right)=\bar{u}^{\mathrm{V}_{\mathrm{S}}(x)}$, bar denoting the image modulo $m_{\mathrm{S}}$. Since $\left(h h_{1}(x)\right)$ is not a square in the finite field $\mathrm{\kappa}(x), u(x)$ is a square in $\kappa(x)\left(\sqrt{h h_{1}(x)}\right)$. Since $\kappa(x)\left(\sqrt{\left(h h_{1}\right)(x)}\right) \subset \mathrm{S} / m_{\mathrm{S}}, \bar{u}$ is a square in $\mathrm{S} / m_{\mathrm{S}}$ and hence $(u) \cdot\left(\pi_{x}\right)$ is unramified on S. Suppose that $h(x)=0$. Since $h_{1}(x)$ is a unit at $x$ and $\operatorname{Supp}_{\text {Spec(B) }}(h) \subset \operatorname{Supp}(\mathrm{C}+\mathrm{E})$, $h h_{1}$ is a local equation for C at $x, \pi_{x}=h h_{1} v, v \in \mathrm{~A}^{*}$ and $\alpha=\alpha^{\prime}+(u) \cdot\left(h h_{1} v\right)$. Since $(u) \cdot\left(h h_{1} v\right)_{\mathrm{L}}=(u) \cdot(v)_{\mathrm{L}}, \alpha$ is unramified at S. Similarly, one proves that $\alpha$ is unramified at S , if $x \in \mathrm{E} \cap \mathrm{F}$.

Suppose that $x \in \mathrm{C} \cap \mathrm{E}$. Let $\pi_{x}$ and $\delta_{x}$ be local equations for C and E at $x$ given in the statement of the proposition. Then we have $f=\pi_{x} \delta_{x} w_{x}^{\prime}$ with $w_{x}^{\prime} \in \mathrm{A}^{*}$. We have ([S], 1.2) $\alpha=\alpha^{\prime}+\alpha^{\prime \prime}$, where $\alpha^{\prime}$ is unramified on A and $\alpha^{\prime \prime}$ is a sum of symbols of the type $(u) \cdot\left(\pi_{x}\right),(v) \cdot\left(\delta_{x}\right)$ and $\left(\pi_{x}\right) \cdot\left(\delta_{x}\right), u, v \in \mathrm{~A}^{*}$. For $u \in \mathrm{~A}^{*}$, we have
$\left.{ }^{*}\right)(u) \cdot\left(\delta_{x}\right)_{L}=(u) \cdot\left(\delta_{x} f\right)_{\mathrm{L}}=(u) \cdot\left(\pi_{x} w_{x}^{\prime}\right)_{\mathrm{L}}$,
$\left.{ }^{* *}\right)(u) \cdot\left(\pi_{x}\right)_{\mathrm{L}}=(u) \cdot\left(\pi_{x} f\right)_{\mathrm{L}}=(u) \cdot\left(\delta_{x} w_{x}^{\prime}\right)_{\mathrm{L}}$,
${ }^{(* * *)}\left(\pi_{x}\right) \cdot\left(\boldsymbol{\delta}_{x}\right)_{\mathrm{L}}=\left(\pi_{x} f\right) \cdot\left(\boldsymbol{\delta}_{x}\right)_{\mathrm{L}}=\left(\boldsymbol{\delta}_{x} w_{x}^{\prime}\right) \cdot\left(\boldsymbol{\delta}_{x}\right)_{\mathrm{L}}=\left(-w_{x}^{\prime}\right) \cdot\left(\boldsymbol{\delta}_{x}\right)_{\mathrm{L}}$.
Suppose further that $h(x) \neq 0$. Then $h h_{1}(x)$ is not a square in $\kappa(x)$. As before, $(v) \cdot\left(\pi_{x}\right)_{\mathrm{L}}$ and $(v) \cdot\left(\delta_{x}\right)_{\mathrm{L}}$ are unramified at S for any $v \in \mathrm{~A}^{*}$. Therefore $\alpha_{\mathrm{L}}$ is unramified at S. Suppose that $h(x)=0$. Then either $h=\pi_{x} w_{x}$ or $h=\delta_{x} w_{x}$ or $h=\pi_{x} \delta_{x} w_{x}$, where $w_{x} \in \mathrm{~A}^{*}$. If $h=\pi_{x} w_{x}$ or $\delta_{x} w_{x}$, then, by $(*),(* *),(* * *)$ it follows that $\partial_{\mathrm{s}}\left(\mathbf{\alpha}^{\prime \prime}\right)=0$ and hence $\boldsymbol{\alpha}$ is unramified at S . Suppose $h=\pi_{x} \delta_{x} w_{x}$. Since $\sqrt{f}, \sqrt{h h_{1}} \in \mathrm{~L}^{*}, \sqrt{w_{x}^{\prime} w_{x} h_{1}} \in \mathrm{~L}^{*}$. Since $\left(w_{x}^{\prime} w_{x} h_{1}\right)(x)$ is not a square in $\mathrm{K}(x)$, once again using $(* * *)$ and arguing as above, it follows that $\alpha^{\prime \prime}$ and hence $\alpha$ is unramified at S .

Let $k^{\prime}$ be the field of constants in L. Let $\mathbf{X}^{\prime}$ be the smooth, projective, irreducible curve over $k^{\prime}$ with L as its function field. Let $\mathscr{X}^{\prime}$ be a regular, projective model of $\mathrm{X}^{\prime}$ over $\mathscr{O}_{k^{\prime}}$. For every $x^{\prime} \in \mathscr{X}^{\prime}$ of codimension $1, \mathscr{O}_{\mathscr{C}^{\prime}, x^{\prime}}$ dominates $\mathscr{O}_{\mathscr{C}, x}$, where $x \in \mathscr{X}$ is a point of codimension 1 or 2 . The element $\alpha_{\mathrm{L}}$ is unramified at $x^{\prime}$ for every $x^{\prime} \in \mathscr{X}^{\prime 1}$. Since the Brauer group of $\mathscr{X}^{\prime}$ is trivial (cf. [L], Theorem 4 or [ Gr ], 2.15 and 3.1), it follows that $\alpha_{\mathrm{L}}=0$. This completes the proof of the proposition.

Corollary 2.2 ([S], 3.4). - Let D be a central division algebra over K of exponent 2 in the Brauer group of K . Then the degree of D is at most 4. In particular, every element in $\mathbf{H}^{2}(\mathbf{K}, \mathbf{Z} / 2)$ is a sum of two symbols.

Proof. - Let $\alpha \in \mathrm{H}^{2}(\mathrm{~K}, \mathbf{Z} / 2)$ denote the class of D . Let $\mathscr{K}, \mathrm{C}$ and E be as in (2.1) defined with respect to $\alpha$. By a semi-local argument, due to Colliot-Thélène
(cf. [HV], Lemma 2.4), we choose $f \in \mathrm{~K}^{*}$ such that

$$
\operatorname{div}_{\mathscr{X}}(f)=\mathrm{C}+\mathrm{E}+\mathrm{F},
$$

where F is a divisor on $\mathscr{\mathscr { C }}$ whose support does not contain any point of $\mathrm{C} \cap \mathrm{E}$ not any component of $\mathbf{C}$ or E . Let T and $\mathbf{B}$ be as in (2.1). Let $h \in \mathbf{B}^{*}$ be such that for every $x \in \mathrm{~T}, h(x)$ is not a square in $\mathrm{K}(x)$. We set $h_{1}=1$. Then $h$ and $h_{1}$ satisfy the hypotheses of (2.1). Therefore by (2.1), the image of $\alpha$ in $\mathrm{H}^{2}(\mathrm{~K}(\sqrt{f}, \sqrt{h}), \mathbf{Z} / 2)$ is zero. Hence $\mathrm{D} \otimes \mathrm{K}(\sqrt{f}, \sqrt{h})$ is a split algebra. In particular, the degree of D is at most 4 and D is a tensor product of two quaternion algebras ([A]). Hence $\alpha$ is a sum of two symbols.

## 3. Cohomology in degree 3

Lemma 3.1. - Let F be a finite field of characteristic not equal to 2 and Y a smooth, projective curve over F . Let $\beta \in \mathrm{H}^{2}(\mathrm{~F}(\mathrm{Y}), \mathbf{Z} / 2)$ and $\mathrm{P}_{1}, \ldots, \mathrm{P}_{n}$ be the closed points of Y where $\beta$ is ramified. Let $f \in \mathrm{~F}(\mathrm{Y})^{*}$ be such that at each $\mathrm{P}_{i}$ either $f$ has odd valuation or $f$ is a unit at $\mathrm{P}_{i}$ and $f\left(\mathrm{P}_{i}\right)$ is not a square in $\mathbf{\kappa}\left(\mathrm{P}_{i}\right)$. Then $\beta \otimes \mathrm{F}(\mathrm{Y})(\sqrt{f})=0$.

Proof. - By class field theory, it is enough to prove that $\beta \otimes \mathrm{F}(\mathrm{Y})(\sqrt{f})$ is unramified at each discrete valuation ring of $\mathrm{F}(\mathrm{Y})(\sqrt{f})$. Let S be a discrete valuation ring with $\mathrm{F}(\mathrm{Y})(\sqrt{f})$ as its quotient field. Let R be the discrete valuation ring of $\mathrm{F}(\mathrm{Y})$ such that $\mathrm{R} \subset S$. If $\beta$ is unramified at R , then $\beta$ is unramified at S . Suppose that $\beta$ is ramified at R and $\mathrm{R}=\mathscr{O}_{\mathrm{Y}, \mathrm{P}_{i}}$ for some $i$. If $f$ has odd valuation at $\mathrm{P}_{i}$, then S over R is ramified and hence $\beta$ is unramified at S . If $f$ has even valuation at $\mathrm{P}_{i}$, then by the choice of $f, f$ is a unit at $\mathrm{P}_{i}$ and not a square in $\mathrm{k}\left(\mathrm{P}_{i}\right)$. Therefore the residue field $\overline{\mathrm{S}}$ of S is a quadratic extension of the residue field $\kappa\left(P_{i}\right)$ at $R$. Since $S$ over $R$ is unramified, $\partial_{\mathrm{S}}\left(\boldsymbol{\alpha}_{\mathrm{L}}\right)=\partial_{\mathrm{R}}(\boldsymbol{\alpha}) \otimes_{\mathrm{K}\left(\mathrm{P}_{i}\right)} \overline{\mathrm{S}}$ (cf. [S]. 1.3). Since $\overline{\mathrm{S}}$ is a quadratic extension of $\boldsymbol{\kappa}\left(\mathrm{P}_{i}\right)$ and $\boldsymbol{\kappa}\left(\mathrm{P}_{i}\right)$ is a finite field, every element of $\boldsymbol{\kappa}\left(\mathrm{P}_{i}\right)$ is a square in $\overline{\mathrm{S}}$. Therefore $\beta$ is unramified at $S$.

Lemma 3.2. - Let R be a discrete valuation ring, K its quotient field and $\mathrm{\kappa}$ its residue field, with char $\kappa \neq 2$. Let $\delta$ be a parameter in R and $u \in \mathrm{R}^{*}$. If $(u) \cdot(\boldsymbol{\delta})$ is unramified at R , then $(u) \cdot(\boldsymbol{\delta})=(u) \cdot\left(u^{\prime}\right)$ for some $u^{\prime} \in \mathbf{R}^{*}$.

Proof. - Suppose that $(u) \cdot(\delta)$ is unramified at R. Since $\partial_{\mathrm{R}}((u) \cdot(\delta))=(\bar{u})$, where bar denotes the image in $\kappa, \bar{u}$ is a square in $\kappa$. Let $a \in \mathrm{R}$ be such that $\bar{a}^{2}=\bar{u}$. We write $a^{2}-u=v \boldsymbol{\delta}^{r}$ for some $r \geqslant 1$ and $v \in \mathbf{R}^{*}$. Suppose that $r \geqslant 2$. We have $(a+\delta)^{2}-u=v \delta^{r}+\delta^{2}+2 a \delta=\delta\left(v \delta^{r-1}+\delta+2 a\right)$. Since $r \geqslant 2$ and $a$ is a unit in R, $v \boldsymbol{\delta}^{r-1}+\delta+2 a$ is a unit in R. Replacing $a$ by $a+\delta$ we assume that $r=1$. Therefore we have, $(u) \cdot(\boldsymbol{\delta})=\left(a^{2}-v \boldsymbol{\delta}\right) \cdot(\boldsymbol{\delta})=\left(1-a^{-2} v \boldsymbol{\delta}\right) \cdot(\boldsymbol{\delta})=($ since $(x) \cdot(1-x)$ is trivial $)$ $\left(1-a^{-2} v \delta\right) \cdot\left(a^{-2} v \boldsymbol{\delta}^{2}\right)=\left(1-a^{-2} v \boldsymbol{\delta}\right) \cdot(v)=(u) \cdot(v)$.

Proposition 3.3. - Let A be a regular local ring of dimension 2, K its quotient field and $\mathrm{\kappa}$ its residue field, with char $\kappa \neq 2$. For every regular parameter $\pi$ of A (i.e., $\mathrm{A} /(\boldsymbol{\pi})$ is regular) with residue field $\mathbf{\kappa}(\pi)$, suppose that every element of $\mathbf{H}^{2}(\boldsymbol{\kappa}(\pi), \mathbf{Z} / 2)$ is represented by a symbol $(a) \cdot(b)$ for some $a, b \in \mathbb{K}(\pi)^{*}$. Let $\alpha \in \mathbf{H}^{3}(\mathbf{K}, \mathbf{Z} / 2)$.
(i) Suppose $\alpha$ is ramified only at $\pi$ among the prime elements of A. Assume that $\pi$ is a regular parameter in A . Then

$$
\alpha=\alpha^{\prime}+(u) \cdot(v) \cdot(\pi)
$$

for some $\alpha^{\prime} \in \mathrm{H}_{\mathrm{nr}}^{3}(\mathrm{~K} / \operatorname{Spec}(\mathrm{A}), \mathbf{Z} / 2)$ and $u, v \in \mathrm{~A}^{*}$.
(ii) Suppose $\alpha$ is ramified only at $\pi$ and $\delta$ among the prime elements of A. Further assume that $\pi$ and $\delta$ generate the maximal ideal $m$ of A . Then

$$
\alpha=\alpha_{1}+\alpha_{2},
$$

where $\boldsymbol{\alpha}_{1} \in \mathrm{H}_{\mathrm{nr}}^{3}(\mathrm{~K} / \operatorname{Spec}(\mathrm{A}), \mathbf{Z} / 2)$ and $\boldsymbol{\alpha}_{2}$ is a sum of symbols of the type

$$
(u) \cdot(v) \cdot(\pi), \quad(u) \cdot(v) \cdot(\delta), \quad(u) \cdot(\delta) \cdot(\pi),
$$

$u$, $v$ running over the units of A .
Proof. - Let $\alpha$ and $\pi$ be as in (i). Since $\pi$ is a regular parameter of A, there exists a prime element $\delta$ in A such that the maximal ideal $m$ of A is generated by $\pi$ and $\delta$. We have a complex ([K], Prop. 1.7)

$$
\mathrm{H}^{3}(\kappa, \mathbf{Z} / 2) \xrightarrow{\partial} \bigoplus_{x \in \operatorname{Spec}(\mathrm{~A})^{1}} \mathrm{H}^{2}(\kappa(x), \mathbf{Z} / 2) \xrightarrow{\partial} \mathbf{H}^{1}(\kappa, \mathbf{Z} / 2):
$$

By the assumption on $\kappa(\pi)$, there exist $a, b \in \mathrm{~A}$ such that $\partial_{\pi}(\alpha)=(\bar{a}) \cdot(\bar{b})$, bar denoting the image in $\mathrm{A} /(\pi)$. Since $m$ is generated by $\pi$ and $\delta, \mathrm{A} /(\pi)$ is a discrete valuation ring with $\bar{\delta}$ as a parameter. Without loss of generality we assume that $\partial_{\pi}(\alpha)$ is equal to either $(\bar{u}) \cdot(\bar{v})$ or $(\bar{u}) \cdot(\bar{v} \bar{\delta})$ for some $u, v \in \mathrm{~A}^{*}$. Suppose $\partial_{\pi}(\alpha)=(\bar{u}) \cdot(\bar{v} \bar{\delta})$. Since $\alpha$ has residue only at $\pi, \partial \partial(\alpha)=\partial((\bar{u}) \cdot(\bar{v} \bar{\delta}))$ is the square class of the image of $u$ in $\kappa^{*}$. Since $\partial \partial=0, u$ is a square modulo $m$. Thus $(\bar{u}) \cdot(\bar{v} \bar{\delta})$ over $\kappa(\pi)$ is unramified at $\bar{\delta}$ and by $(3.2)(\bar{u}) \cdot(\bar{v} \bar{\delta})=(\bar{u}) \cdot(\bar{v})$ for some $v^{\prime} \in \mathrm{A}^{*}$. Thus we assume that $\partial_{\pi}(\boldsymbol{\alpha})=(\bar{u}) \cdot(\bar{v})$ for some $u, v \in \mathrm{~A}^{*}$. Let $\alpha^{\prime}=\alpha-(u) \cdot(v) \cdot(\pi)$. Since $\partial_{\pi}(\boldsymbol{\alpha})=\partial_{\pi}((\bar{u}) \cdot(\bar{v}) \cdot(\pi))$ and $\partial_{\pi^{\prime}}((u) \cdot(v) \cdot(\pi))=\partial_{\pi^{\prime}}(\boldsymbol{\alpha})=0$ for any prime element $\pi^{\prime}$ of A not equal to $\pi$, we have $\partial\left(\boldsymbol{\alpha}^{\prime}\right)=0$. Hence $\boldsymbol{\alpha}^{\prime} \in \mathrm{H}_{\mathrm{nr}}^{3}(\mathrm{~K} / \operatorname{Spec}(\mathbf{A}), \mathbf{Z} / 2)$ and $\boldsymbol{\alpha}=\boldsymbol{\alpha}^{\prime}+(u) \cdot(v) \cdot(\pi)$.

Now let $\alpha, \pi$ and $\delta$ be as in (ii). Since every element in $H^{2}(\boldsymbol{\kappa}(\pi), \mathbf{Z} / 2)$ is represented by a symbol, there exist $u, v \in \mathrm{~A}^{*}$, such that $\partial_{\pi}(\boldsymbol{\alpha})$ is equal to $(\bar{u}) \cdot(\bar{v})$ or $(\bar{u}) \cdot(\bar{v} \bar{\delta})$. Set $\alpha_{1}=\alpha-(u) \cdot(v) \cdot(\pi)$ if $\partial_{\pi}(\boldsymbol{\alpha})=(\bar{u}) \cdot(\bar{v})$ and $\alpha_{1}=\alpha-(u) \cdot(v \delta) \cdot(\pi)$ if $\partial_{\pi}(\boldsymbol{\alpha})=(\bar{u}) \cdot(\bar{v} \bar{\delta})$. Since $\alpha$ is ramified only at $\pi$ and $\delta, \alpha_{1}$ is unramified except possibly at $\delta$. Now we can apply (i) to describe $\alpha_{1}$. This completes the proof of the proposition.

Remark 3.4. - Suppose that in the above proposition, K is a function field in one variable over a non-dyadic local field $k, \mathscr{B}$ a regular 2 -dimensional scheme over the integers $\mathscr{O}_{k}$ and A the local ring at a codimension 2 point of $\mathscr{C}$. Then for every prime $\pi \in \mathrm{A}$, the residue field $\kappa(\pi)$ at $\pi$ is either a local field or a function field in one variable over a finite field. Therefore every element in $\mathrm{H}^{2}(\mathrm{~K}(\pi), \mathbf{Z} / 2)$ is represented by a symbol. Thus A satisfies the hypothesis of (3.3).

Let $k$ be a non-dyadic $p$-adic field and $\mathscr{O}_{k}$ the ring of integers in $k$. Let X be a smooth, projective, irreducible curve over $k$ and $\mathrm{K}=k(\mathbf{X})$ the function field of $\mathbf{X}$ over $k$.

Let $\alpha \in \mathrm{H}^{3}(\mathbf{K}, \mathbf{Z} / 2)$. Let $\mathscr{X}$ be a regular, projective model of X over $\mathscr{O}_{k}$ such that

$$
\operatorname{ram}_{\mathscr{E}}(\alpha) \subset \mathrm{C}+\mathrm{E},
$$

where C and E are regular curves on $\mathscr{C}$ having only normal crossings.
Lemma 3.5. - Let $k$, K and $\mathscr{B}$ be as above. Let $x$ be a codimension 2 point of $\mathscr{X}$ and $\mathrm{A}=\mathscr{O}_{\mathscr{K}, x}$. Let S be a discrete valuation ring which dominates A . Then every symbol of the type $(u) \cdot(v) \cdot(\pi)$, with $u, v \in \mathrm{~A}^{*}$ and $\pi \in \mathrm{K}^{*}$, is unramified at S .

Proof. - Let $u, v \in \mathrm{~A}^{*}$. We have $\partial_{\mathrm{S}}((u) \cdot(v) \cdot(\pi))=((\bar{u}) \cdot(\bar{v}))^{v_{\mathrm{S}}(\pi)}$, bar denoting the image in the residue field of S and $\mathrm{v}_{\mathrm{S}}$ denoting the valuation of S . Since $u, v \in \mathrm{~A}^{*}$ and $\boldsymbol{K}(x)$ is a finite field, it follows that $(\bar{u}) \cdot(\bar{v})=0$. Hence $(u) \cdot(v) \cdot(\pi)$ is unramified at S.

Lemma 3.6. - Let $k, \mathrm{~K}, \alpha \in \mathrm{H}^{3}(\mathrm{~K}, \mathbf{Z} / 2), \mathscr{C}, \mathrm{C}$ and E be as above. Let L be an extension of K and S a discrete valuation ring with quotient field L . Suppose that there exists $x \in \mathrm{C} \cap \mathrm{E}$ such that S dominates $\mathscr{O}_{\mathscr{R}, x^{*}}$. Suppose one of the following conditions holds.
(i) The residue field of S contains a quadratic extension of $\mathrm{K}(x)$.
(ii) There exist local equations $\pi_{x}, \delta_{x}$ for C and E respectively at $x$ such that either $\pi_{x}$ or $\delta_{x}$ or $\pi_{x} \delta_{x}$ is of the form $w \theta^{2}, \theta \in \mathrm{~S}, w \in \mathrm{~S}^{*}$, with the image of $w$ in the residue field of S having its square class coming from $\mathbf{\kappa}(x)^{*}$.

Then $\alpha_{\mathrm{L}}$ is unramified at $S$.
Proof. - Let $\mathrm{A}=\mathscr{O}_{\mathscr{X}, x}$. By (3.3), $\alpha=\alpha^{\prime}+\alpha^{\prime \prime}$, where $\alpha^{\prime}$ is unramified on A and $\alpha^{\prime \prime}$ is a sum of the symbols of the type $(u) \cdot(v) \cdot\left(\pi_{x}\right),(u) \cdot(v) \cdot\left(\delta_{x}\right),(u) \cdot\left(\pi_{x}\right) \cdot\left(\delta_{x}\right)$, with $u, v \in \mathrm{~A}^{*}$. Let $v_{\mathrm{S}}$ denote the discrete valuation of S , $\partial_{\mathrm{S}}$ denote the residue homomorphism at S and $m_{\mathrm{S}}$ denote the maximal ideal of S. By (3.5), $(u) \cdot(v) \cdot\left(\boldsymbol{\pi}_{x}\right),(u) \cdot(v) \cdot\left(\delta_{x}\right)$ are unramified at S .

Suppose that the residue field of S contains a quadratic extension of $\kappa(x)$. We have

$$
\partial_{\mathrm{S}}\left((u) \cdot\left(\pi_{x}\right) \cdot\left(\delta_{x}\right)\right)=(\bar{u}) \cup \partial_{\mathrm{S}}\left(\left(\pi_{x}\right) \cdot\left(\delta_{x}\right)\right) .
$$

Since the unique quadratic extension of $\kappa(x)$ is contained in the residue field of $S, \bar{u}$ is a square in the residue field of S . Therefore $\partial_{\mathrm{S}}\left(\boldsymbol{\alpha}_{\mathrm{L}}\right)=0$.

Suppose that $\pi_{x}=w \theta^{2}$ for some $w \in \mathrm{~S}^{*}$ such that $\bar{w}=\lambda \lambda_{1}^{2}$ with $\lambda \in \kappa(x)^{*}$, and $\theta \in \mathrm{S}$. Then, we have $\left((u) \cdot\left(\pi_{x}\right) \cdot\left(\delta_{x}\right)_{\mathrm{L}}=\left((u) \cdot(w) \cdot\left(\delta_{x}\right)_{\mathrm{L}}\right.\right.$. We have $\partial_{\mathrm{S}}\left((u) \cdot\left(\boldsymbol{\pi}_{x}\right) \cdot\left(\delta_{x}\right)\right)=$ $((\bar{u}) \cdot(\bar{w}))^{v_{s}\left(\delta_{x}\right)}=((\bar{u}) \cdot(\lambda))^{v_{s}\left(\delta_{x}\right)}$. Since $\bar{u}, \lambda \in \mathrm{~K}(x)^{*}$, as before, it follows that $(\bar{u}) \cdot(\lambda)=0$. Similarly, one can prove that if $\delta_{x}=w \theta^{2}$, with $w, \theta$ as above, then $\partial_{\mathrm{S}}\left((u) \cdot\left(\pi_{x}\right) \cdot\left(\delta_{x}\right)\right)=0$. Suppose that $\pi_{x} \delta_{x}=w \theta^{2}$, with $w, \theta$ as above. Since $(u) \cdot\left(\pi_{x}\right) \cdot\left(\delta_{x}\right)=(u) \cdot\left(-\pi_{x} \delta_{x}\right) \cdot\left(\delta_{x}\right)$, we have $\left((u) \cdot\left(\pi_{x}\right) \cdot\left(\delta_{x}\right)\right)_{\mathrm{L}}=\left((u) \cdot(-w) \cdot\left(\delta_{x}\right)\right)_{\mathrm{L}}$ and $\partial_{\mathrm{S}}\left(\left((u) \cdot\left(\pi_{x}\right) \cdot\left(\delta_{x}\right)_{\mathrm{L}}\right)=((\bar{u}) \cdot(-\bar{w}))^{\mathrm{V}_{\mathbf{S}}\left(\pi_{x}\right)}=0\right.$. Therefore $\alpha$ is unramified at S .

Lemma 3.7. - Let $k$ and K be as in (3.6). Let A be a regular local ring of dimension 2 with K as its quotient field. and S a discrete valuation ring containing A . Then the map $\mathrm{H}^{3}(\mathrm{~K}, \mathbf{Z} / 2) \rightarrow \mathrm{H}^{3}(\mathrm{~L}, \mathbf{Z} / 2)$ restricts to a map

$$
\mathrm{H}_{\mathrm{nr}}^{3}(\mathrm{~K} / \operatorname{Spec}(\mathbf{A}), \mathbf{Z} / 2) \rightarrow \mathrm{H}_{\mathrm{nr}}^{3}(\mathrm{~L} / \operatorname{Spec}(\mathbf{S}), \mathbf{Z} / 2) .
$$

Proof. - The lemma follows from the absolute purity theorem of Gabber for two dimensional regular local rings. We give a proof here for the sake of completeness.

Let W(A) denote the Witt group of A. Since A is a two-dimensional regular local ring, one has the following exact sequence ([O], [CS])

$$
0 \rightarrow \mathrm{~W}(\mathrm{~A}) \rightarrow \mathrm{W}(\mathrm{~K}) \rightarrow \bigoplus_{x \in \operatorname{Spec}(\mathrm{~A})^{1}} \mathrm{~W}(\kappa(x)) .
$$

For $n \geqslant 0$, let $\mathbf{I}_{n}(\mathbf{A}):=\mathrm{I}^{n}(\mathbf{K}) \cap \mathrm{W}(\mathbf{A})$. Since $\mathrm{cd}(\mathbf{K}) \leqslant 3$ and $\mathrm{cd}(\kappa(x)) \leqslant 2$, in view of ([AEJ], Theorem 2), the homomorphisms $e_{n}: \mathrm{I}^{n}(\mathrm{~F}) \rightarrow \mathrm{H}^{n}(\mathrm{~F}, \mathbf{Z} / 2)$ exist and are surjective with kernel $\mathrm{I}^{n+1}(\mathrm{~F})$, for $\mathrm{F}=\mathrm{K}$ or $\mathrm{K}(x)$. Since the following diagram is commutative (cf. [P]),

with $e_{3}$ and $e_{2}$ isomorphisms, $e_{3}$ induces an isomorphism

$$
e_{3}: \mathrm{I}_{3}(A) \rightarrow \mathrm{H}_{\mathrm{nr}}^{3}(\mathrm{~K} / \operatorname{Spec}(\mathbf{A}), \mathbf{Z} / 2)
$$

Let $\alpha \in \mathrm{H}_{\mathrm{nr}}^{3}(\mathbf{K} / \operatorname{Spec}(\mathbf{A}), \mathbf{Z} / 2)$ and $q \in \mathrm{I}_{3}(\mathbf{A})$ with $e_{3}(q)=\alpha$. Then $q_{\mathrm{L}} \in \mathrm{I}_{3}(\mathbf{S})$ and $\alpha_{\mathrm{L}}=e_{3}\left(q_{\mathrm{L}}\right)$ in $\mathrm{H}^{3}(\mathrm{~L}, \mathbf{Z} / 2)$. In view of the following commutative diagram

we have $\partial_{\mathrm{S}}\left(\boldsymbol{\alpha}_{\mathrm{L}}\right)=\partial_{\mathrm{S}}\left(e_{3}\left(q_{\mathrm{L}}\right)\right)=e_{2} \partial_{\mathrm{S}}\left(q_{\mathrm{L}}\right)=0$.
Thus $\alpha_{\mathrm{L}} \in \mathrm{H}_{\mathrm{nr}}^{3}(\mathrm{~L} / \operatorname{Spec}(\mathbf{S}), \mathbf{Z} / 2)$.
Theorem 3.8. - Let $k$ be a non-dyadic p-adic field, X a smooth, projective, irreducible curve over $k$. Let $\mathrm{K}=k(\mathbf{X})$ and $\alpha_{i} \in \mathrm{H}^{3}(\mathbf{K}, \mathbf{Z} / 2), 1 \leqslant i \leqslant n$. Then there exists $f \in \mathrm{~K}^{*}$ such that $\boldsymbol{\alpha}_{i} \otimes \mathbf{K}(\sqrt{f})=0$ for $1 \leqslant i \leqslant n$.

Proof. - Let $\mathscr{X}$ be a regular, projective model of X over $\mathscr{O}_{k}$ with

$$
\cup_{i=1}^{n} \operatorname{Supp}\left(\operatorname{ram}_{\mathscr{B}}\left(\alpha_{i}\right)\right) \subset \operatorname{Supp}(\mathrm{C}+\mathrm{E}),
$$

where C and E are regular curves on $\mathscr{X}$ with only normal crossings. Let $f \in \mathrm{~K}^{*}$ be such that

$$
\operatorname{div}_{\mathscr{C}}(f)=\mathrm{C}+\mathrm{E}+\mathrm{F},
$$

where F is a divisor on $\mathscr{X}$ whose support does not contain any point of $\mathrm{C} \cap \mathrm{E}$, nor any component of C or E . Let $\mathrm{L}=\mathrm{K}(\sqrt{f})$. Let $k^{\prime}$ be the field of constants in L. Let $\mathrm{X}^{\prime}$ be the smooth, projective, irreducible curve over $k^{\prime}$ with function field L. Let $\mathscr{K}^{\prime}$ be a regular, projective model for $\mathrm{X}^{\prime}$ over $\mathscr{O}_{k^{\prime}}$. Fix $i, 1 \leqslant i \leqslant n$ and let $\alpha=\boldsymbol{\alpha}_{i}$. We show that $\alpha_{\mathrm{L}} \in \mathrm{H}_{\mathrm{nr}}^{3}\left(\mathrm{~L} / \mathscr{X}^{\prime}, \mathbf{Z} / 2\right)$. Let $y \in \mathscr{X}^{\prime}$ be a point of codimension 1 and $\mathrm{S}=\mathscr{O}_{\mathscr{C}}{ }^{\prime}, \nu$ be the discrete valuation ring at $y$. Since $\mathscr{X}$ is proper over $\mathscr{O}_{k}$, there exists a point $x \in \mathscr{X}$ of codimension 1 or 2 , such that S dominates the local ring $\mathrm{A}=\mathscr{O}_{\mathscr{X}, x^{\prime}}$.

Suppose $\operatorname{dim}(A)=1$. Then $A$ is a discrete valuation ring. If $x$ corresponds to a component of C or E , then $f$ is a parameter at $x$ and S over A is ramified. Hence, $\alpha_{\mathrm{L}}$ is unramified at S . Suppose that $x$ does not correspond to a component of C or E. Since $\operatorname{ram}_{\mathscr{S}}(\alpha) \subset \mathrm{C}+\mathrm{E}, \alpha$ is unramified at R and hence $\alpha_{\mathrm{L}}$ is unramified at S .

Suppose $\operatorname{dim}(A)=2$. Suppose first that $x$ does not belong to $\operatorname{Supp}(C) \cup \operatorname{Supp}(E)$. Then $\alpha$ is unramified on A and hence unramified at $S$ (3.7). Suppose $x \in \operatorname{Supp}(C) \backslash$ $\operatorname{Supp}(\mathrm{E})$ or $x \in \operatorname{Supp}(\mathrm{E}) \backslash \operatorname{Supp}(\mathrm{C})$, then by (3.3) and (3.5), $\alpha$ is unramified on A and hence by (3.7), $\alpha_{\mathrm{L}}$ is unramified at S . Suppose that $x \in \operatorname{Supp}(\mathrm{C}) \cap \operatorname{Supp}(\mathrm{E})$. Let $\pi_{x}$ and $\delta_{x}$ be local equations for C and E at $x$ respectively. Then we have $f=\pi_{x} \delta_{x} w$ for some $w \in \mathrm{~A}^{*}$. Since $f$ is a square in L , it follows from (3.6) that $\alpha_{\mathrm{L}}$ is unramified at S . Therefore $\alpha_{\mathrm{L}} \in \mathrm{H}_{\mathrm{nr}}^{3}\left(\mathrm{~L} / \mathscr{X}^{\prime}, \mathbf{Z} / 2\right)$. Since $\mathrm{H}_{\mathrm{nr}}^{3}\left(\mathrm{~L} / \mathscr{K}^{\prime}, \mathbf{Z} / 2\right)=0([\mathrm{~K}], 5.2)$, we have $\alpha_{\mathrm{L}}=0$.

Theorem 3.9. - Let $k$ be a non-dyadic $p$-adic field and K a function field in one variable over $k$. Let $\boldsymbol{\alpha}_{i} \in \mathbf{H}^{3}(\mathbf{K}, \mathbf{Z} / 2), 1 \leqslant i \leqslant n$. Then there exist $f, g, h_{i} \in \mathbf{K}^{*}$ such that $\boldsymbol{\alpha}_{i}=(f) \cdot(g) \cdot\left(h_{i}\right)$. In particular, every element in $\mathrm{H}^{3}(\mathbf{K}, \mathbf{Z} / 2)$ is a symbol.

Proof. - By (3.8), there exists $h \in \mathbf{K}^{*}$ such that $\boldsymbol{\alpha}_{i} \otimes \mathrm{~K}(\sqrt{h})=0$, for $1 \leqslant i \leqslant n$. Therefore, there exist ([Ar], 4.6) $\boldsymbol{\beta}_{i} \in \mathbf{H}^{2}(\mathbf{K}, \mathbf{Z} / 2)$, such that $\boldsymbol{\alpha}_{i}=(h) \cup \boldsymbol{\beta}_{i}$, for $1 \leqslant i \leqslant n$. Let X be a smooth, projective, irreducible curve over $k$ with $k(\mathbf{X})=\mathrm{K}$. Let $\mathscr{X}$ be a regular, projective model of X over $\mathscr{O}_{k}$ such that

$$
\cup_{i=1}^{n} \operatorname{Supp}\left(\operatorname{ram}_{\mathscr{X}}\left(\boldsymbol{\beta}_{i}\right)\right) \cup \operatorname{Supp}_{\mathscr{X}}(h) \subset \operatorname{Supp}(\mathrm{C}+\mathrm{E})
$$

where C and E are as before. Let $f \in \mathrm{~K}^{*}$ be such that

$$
\operatorname{div}_{\mathscr{C}}(f)=\mathrm{C}+\mathrm{E}+\mathrm{F},
$$

where F is a divisor on $\mathscr{B}$ whose support does not contain any point of $\mathrm{C} \cap \mathrm{E}$, nor any component of C or E . Let T be the finite set of codimension 2 points of $\mathscr{X}$ consisting of $\mathrm{C} \cap \mathrm{E}, \mathrm{C} \cap \mathrm{F}$ and $\mathrm{E} \cap \mathrm{F}$. Let B be the semi local ring at T . Since $\mathscr{B}$ is regular, B is a regular ring and hence a unique factorisation domain with quotient field K . Hence, without loss of generality, we assume that $h \in \mathrm{~B}$ and is square free with $\operatorname{Supp}_{\mathrm{Spec}(\mathrm{B})}(h) \subset \operatorname{Supp}(\mathrm{C}+\mathrm{E})$. Let $x \in \mathrm{C} \cap \mathrm{E}$. Let $\pi_{x}$ and $\delta_{x}$ be local equations at $x$ for C and E respectively. Then $h=\pi_{x}^{\varepsilon_{1}} \delta_{x}^{\varepsilon_{2}} w_{x}$ and $f=\pi_{x} \delta_{x} w_{x}^{\prime}$, where $w_{x}, w_{x}^{\prime} \in \mathrm{B}$ are units at $x$ and $\varepsilon_{1}, \varepsilon_{2} \in\{0,1\}$. Choose $w \in \mathrm{~B}^{*}$ such that $w$ is a unit at one closed point of each component of C and E and $-w(x) w_{x}(x) w_{x}^{\prime}(x)$ is not a square in $\kappa(x)$. Replacing $f$ by $w f$, we assume that $-w_{x}(x) w_{x}^{\prime}(x)$ is not a square in $\kappa(x)$ for all $x \in \mathrm{C} \cap \mathrm{E}$ and $\operatorname{div}_{\mathscr{C}}(f)=\mathrm{C}+\mathrm{E}+\mathrm{F}^{\prime}$, with $\mathrm{C}, \mathrm{E}$ as above and $\mathrm{F}^{\prime}$ is a divisor on $\mathscr{O}$ whose support does not contain any point of $\mathrm{C} \cap \mathrm{E}$ and any component of C or E . We claim that there exist $a_{i} \in \mathrm{~K}^{*}$ such that $\boldsymbol{\alpha}_{i}=(h) \cdot(f) \cdot\left(a_{i}\right), 1 \leqslant i \leqslant n$. For $x \in \mathrm{~T}$,
(i) if $h(x) \neq 0$, let $a_{x}, b_{x} \in \mathrm{~K}(x)$ be such that $h(x)\left(h(x) a_{x}^{2}-b_{x}^{2}\right)$ is not a square.
(ii) if $h(x)=0$, let $a_{x}=0$ and $b_{x}=1$ in $\kappa(x)$.

Let $a, b \in \mathrm{~B}$ be such that $a(x)=a_{x}$ and $b(x)=b_{x}$ for all $x \in \mathrm{~T}$. Let $h_{1}=h a^{2}-b^{2}$. Since $-w_{x}(x) w_{x}^{\prime}(x)$ is not a square in $\boldsymbol{\kappa}(x)$ for any $x \in \mathrm{C} \cap \mathrm{E}$, it is easy to see that $f, h, h_{1}$ satisfy the conditions in (2.1). Therefore, by (2.1), $\beta_{i} \otimes \mathbf{K}\left(\sqrt{f}, \sqrt{h h_{1}}\right)=0$, for $1 \leqslant i \leqslant n$. Hence there exist $a_{i}, b_{i} \in \mathrm{~K}^{*}$ such that $\beta_{i}=(f) \cdot\left(a_{i}\right)+\left(h h_{1}\right) \cdot\left(b_{i}\right)$, for $1 \leqslant i \leqslant n$ (cf. [HV], 3.1). Since $h h_{1}=(h a)^{2}-h b^{2}, h h_{1}$ is norm from $\mathrm{K}(\sqrt{h})$ and hence $(h) \cdot\left(h h_{1}\right)=0$. For $1 \leqslant i \leqslant n$, we have

$$
\begin{aligned}
\boldsymbol{\alpha}_{i} & =(h) \cup \beta_{i} \\
& =(h) \cdot(f) \cdot\left(a_{i}\right)+(h) \cdot\left(h h_{1}\right) \cdot\left(b_{i}\right) \\
& =(h) \cdot(f) \cdot\left(a_{i}\right):
\end{aligned}
$$

This completes the proof of the theorem.

## 4. u-invariant

Theorem 4.1. - Let $k$ be a non-dyadic p-adic field and K a function field in one variable over $k$. Then every element of $\mathrm{I}^{3}(\mathrm{~K})$ is represented by a 3-fold Pfister form.

Proof. - Let $q$ be an anisotropic quadratic form over K representing an element of $\mathbf{I}^{3}(\mathbf{K})$. Let $\alpha=e_{3}(q)$. Then by (3.9), $\alpha=(f) \cdot(g) \cdot(h)$. Since $e_{3}: \mathbf{I}^{3}(\mathbf{K}) \rightarrow \mathbf{H}^{3}(\mathbf{K}, \mathbf{Z} / 2)$ is an isomorphism ([AEJ], Theorem 2), $q=<1,-f><1,-g><1,-h>$ in $\mathrm{I}^{3}(\mathrm{~K})$. Since $q$ is anisotropic, $q \simeq<1,-f><1,-g><1,-h>$.

Corollary 4.2. - Let K be as in (4.1). Then every quadratic form over K of rank at least 13 is isotropic.

Proof. - Let $q$ be a quadratic form over $q$ of rank 13. By the theorem of Saltman (cf. 2.2), $c(q)$ is a biquaternion algebra over K . Let $q_{0}$ be a quadratic form over K such that $\mathrm{rk}\left(q_{0}\right)=5, d\left(q+q_{0}\right)=1$ and $c\left(q+q_{0}\right)=0$ (cf. [HV], 3.2). Then $q+q_{0} \in \mathrm{I}^{3}(\mathrm{~K})$ ([M1]). By (4.1), we have $q+q_{0}=<1, f><1, g><1, h>$ for some $f, g, h \in \mathrm{~K}^{*}$. Since rk $(q)=13, q \simeq<1, f><1, g><1, h>\perp-q_{0}$. Since $\mathrm{I}^{4}(\mathbf{K})=0$, every element in $\mathrm{I}^{3}(\mathrm{~K})$ represents every element of $\mathrm{K}^{*}$. In particular $<1, f><1, g><1, h>$ represents a value of $q_{0}$. Therefore $q$ is isotropic.

To prove that every quadratic form over K of rank at least 11 is isotropic, we need a subtler choice of a quadratic extension which splits the given element in $\mathrm{H}^{3}(\mathbf{K}, \mathbf{Z} / 2)$.

Let $k$ be a non-dyadic $p$-adic field, X a smooth, projective, integral curve over $k$ and $\mathrm{K}=k(\mathbf{X})$. Let $\alpha \in \mathrm{H}^{3}(\mathrm{~K}, \mathbf{Z} / 2)$ and $\mathscr{B}$ be a regular, projective model of X over the ring $\mathscr{O}_{k}$ of integers in $k$, such that

$$
\operatorname{ram}_{\mathscr{B}}(\boldsymbol{\alpha}) \subset \mathrm{C}+\mathrm{E},
$$

where C and E are regular curves on $\mathscr{C}$ such that C and E have only normal crossings. Let $\mathrm{T}=\mathrm{C} \cap \mathrm{E}$ and B be the semi-local ring at T . Since $\mathscr{O}$ is regular, B is a regular semi-local ring and hence a unique factorisation domain.

Lemma 4.3. - With the notation as above, let L be a quadratic extension of K. Let S be a discrete valuation ring with L as its quotient field. Assume that $\mathrm{S} \cap \mathrm{K}=\mathrm{B}_{(\pi)}$, where $\pi$ is a prime element in B giving a local equation for a component $\mathrm{C}_{1}$ of C . If $\mathrm{C}_{1} \cap \mathrm{E} \neq \emptyset$, let $\mathrm{C}_{1} \cap \mathrm{E}=\left\{x_{1}, \cdots, x_{r}\right\}$ and $\delta_{x_{i}}$ be a local equation of E at $x_{i}, 1 \leqslant i \leqslant r$. Suppose that either $\mathbf{C}_{1} \cap \mathrm{E}=\emptyset$ or $\mathrm{L}=\mathbf{K}(\sqrt{f})$ with $f \in \mathbf{B}$ satisfying one of the following conditions:
(i) $f$ is a parameter in $\mathbf{B}_{(\pi)}$,
(ii) $f$ is a unit in $\mathrm{B}_{(\pi)}$ such that either $v_{\bar{\delta}_{x_{i}}}(\bar{f})=1$ or $f\left(x_{i}\right)$ is not a square in $\mathrm{\kappa}\left(x_{i}\right), 1 \leqslant i \leqslant r$, where bar denotes the image modulo $(\pi)$ and $v_{\bar{\delta}_{x_{i}}}$ denotes the discrete valuation of $\mathbf{B} /(\pi)$ at $\overline{\boldsymbol{\delta}}_{x_{i}}$.

Then $\alpha_{\mathrm{L}}$ is unramified at S .
Proof. - Let $\mathrm{A}=\mathrm{B}_{(\pi)}$. Then the residue field $\kappa(\pi)$ of A is the quotient field of $\mathrm{B} /(\pi)$. Since $\operatorname{ram}_{\mathscr{X}} \propto \subset \mathrm{C}+\mathrm{E}$ and $\mathrm{C}_{1}$ is a regular curve on $\mathscr{X}$, it follows from the complex ([K], 1.7)

$$
\mathbf{H}^{3}(\mathbf{K}, \mathbf{Z} / 2) \xrightarrow{\partial} \bigoplus_{\eta \in \mathscr{O}^{1}} \mathbf{H}^{2}(\mathbf{\kappa}(\eta), \mathbf{Z} / 2) \xrightarrow{\partial} \bigoplus_{y \in \mathscr{O}^{2}} \mathrm{H}^{1}(\mathbf{\kappa}(y), \mathbf{Z} / 2)
$$

that $\partial_{(\pi)}(\boldsymbol{\alpha})$ is possibly ramified only at the discrete valuations of $\kappa(\pi)$ corresponding to $\mathrm{C}_{1} \cap \mathrm{E}$. Suppose that $\mathrm{C}_{1} \cap \mathrm{E}=\emptyset$. Then it follows that $\partial_{(\pi)}(\boldsymbol{\alpha})$ is unramified at every discrete valuation ring of $\kappa(\pi)$. Since $\kappa(\pi)$ is either a global field of positive characteristic (so that there are no archimedean primes) or a local field, by class field theory, we have $\partial_{(\pi)}(\alpha)=0$ and hence $\alpha_{\mathrm{L}}$ is unramified at S .

Suppose that $\mathrm{C}_{1} \cap \mathrm{E} \neq \emptyset$. Suppose that $f$ is a parameter in A. Then S over A is ramified and hence $\alpha_{\mathrm{L}}$ is unramified at S. Suppose that $f$ is as in (ii). Since $\delta_{\bar{\delta}_{x_{i}}}(\bar{f})=1$ or $f\left(x_{i}\right)$ is not a square in $\mathrm{k}\left(x_{i}\right)$, for $1 \leqslant i \leqslant r$, it follows that $\bar{f}$ is not a square in $\mathrm{B} /(\pi)$. Since C and E have only normal crossings, $\mathrm{B} /(\pi)$ is a regular semi local ring and is integrally closed. Hence $\bar{f}$ is not a square in the residue field $\kappa(\pi)$ of A. Since $\mathrm{H}^{3}(\mathrm{~K}, \mathbf{Z} / 2)$ is generated by symbols and the ramification map is natural on unramified extensions, one sees easily that if $S$ over $A$ is unramified, then $\partial_{S}\left(\alpha_{L}\right)=\partial_{A}(\alpha) \otimes \kappa(\pi)(\sqrt{f})$. Suppose that $\mathbf{\kappa}(\pi)$ is a $p$-adic field. Since the residue field of S is the quadratic extension $\kappa(\pi)(\sqrt{f})$, it follows that $\partial_{\mathrm{A}}(\alpha)$ is split over $\kappa(\pi)(\sqrt{f})$. Since $f$ is a unit in A, S over A is unramified and hence $\partial_{\mathrm{S}}\left(\alpha_{\mathrm{L}}\right)=\partial_{\mathrm{A}}(\boldsymbol{\alpha}) \otimes \mathbb{K}(\pi)(\sqrt{f})=0$ and $\alpha_{\mathrm{L}}$ is unramified at S . Suppose that $\kappa(\pi)$ is a function field in one variable over a finite field. As above, it follows that $\partial_{\mathrm{A}}(\boldsymbol{\alpha})$ can be ramified only at the discrete valuation rings of $\kappa(\pi)$ given by the prime elements $\bar{\delta}_{x_{i}}$ in $\mathrm{B} /(\pi), 1 \leqslant i \leqslant r$. By the assumption on $\bar{f}$, in view of (3.1), $\partial_{\mathrm{A}}(\alpha) \otimes \boldsymbol{\kappa}(\pi)(\sqrt{f})=0$ and the lemma follows.

Proposition 4.4. - Let $k, \mathrm{~K}$ be as above. Let $\alpha \in \mathrm{H}^{3}(\mathrm{~K}, \mathbf{Z} / 2)$ and $a, b \in \mathrm{~K}^{*}$. Then there exists $f \in \mathbf{K}^{*}$ which is a value of the quadratic form $\langle a, b\rangle$ such that $\boldsymbol{\alpha} \otimes \mathbf{K}(\sqrt{f})=0$.

Proof. - Let $\mathscr{X}$ be a regular, projective model of X over $\mathscr{O}_{k}$ such that

$$
\operatorname{Supp}(a) \cup \operatorname{Supp}(b) \cup \operatorname{Supp}\left(\operatorname{ram}_{\mathscr{X}}(\alpha)\right) \subset \operatorname{Supp}(\mathrm{C}+\mathbf{E}),
$$

where C and E are regular curves on $\mathscr{X}$ with only normal crossings. Let $\mathrm{T}=\mathrm{C} \cap \mathrm{E}$. Let B be the semi-local ring at T . For $x \in \mathrm{~T}$, let $\pi_{x}, \delta_{x} \in \mathrm{~B}$ be local equations for C and E at $x$, respectively. Since B is a unique factorisation domain with quotient field K , without loss of generality, we assume that $a, b$ are square free in B and $\operatorname{Supp}_{\mathrm{Spec}(\mathrm{B})}(a b) \subset \operatorname{Supp}(\mathrm{C}+\mathrm{E})$. Let $c \in \mathrm{~B}$ be the greatest common divisor of $a$ and $b$, so that $a=c a^{\prime}, b=c b^{\prime}$, with $a^{\prime}, b^{\prime} \in \mathrm{B}$. Since $a$ and $b$ are square free, $c, a^{\prime}, b^{\prime}$ are pairwise coprime. For $x \in \mathrm{~T}$, choose $u_{x}, v_{x} \in \mathrm{~K}(x)$ as follows:
(i) Suppose $c(x)=0$. Let $m_{x}$ denote the maximal ideal of B at $x$. Since $c, a^{\prime}, b^{\prime}$ are pairwise coprime and the only prime elements of $\mathrm{B}_{m_{x}}$ which divide $c a^{\prime} b^{\prime}$ are $\pi_{x}, \delta_{x}$, at least one of $a^{\prime}$ and $b^{\prime}$ is coprime with $\pi_{x}$ and $\delta_{x}$, and hence is a unit at $x$. Thus $a^{\prime}(x) \neq 0$ or $b^{\prime}(x) \neq 0$. Let $u_{x}, v_{x} \in \mathrm{~K}(x)$ be such that $a^{\prime}(x) u_{x}^{2}+b^{\prime}(x) v_{x}^{2} \neq 0$.
(ii) Suppose that $c(x) \neq 0$ and $a^{\prime} b^{\prime}(x)=0$. Let $u_{x}=v_{x}=1$.
(iii) Suppose that $c(x) a^{\prime}(x) b^{\prime}(x) \neq 0$. Since $\kappa(x)$ is a finite field of characteristic not equal to 2, every element of $\kappa(x)$ is represented by the quadratic form $\left\langle a^{\prime}(x), b^{\prime}(x)\right\rangle$. Let $u_{x}, v_{x} \in \kappa(x)$ be such that $c(x) a^{\prime}(x) b^{\prime}(x)\left(a^{\prime}(x) u_{x}^{2}+b^{\prime}(x) v_{x}^{2}\right) \notin \boldsymbol{\kappa}(x)^{* 2}$.

Let $u, v \in \mathrm{~B}$ be such that $u(x)=u_{x}$ and $v(x)=v_{x}$ for all $x \in \mathrm{~T}$. Let $f=c a^{\prime} b^{\prime}\left(a^{\prime} u^{2}+b^{\prime} v^{2}\right)$. Clearly $f$ is a value of $\left.c<a^{\prime}, b^{\prime}\right\rangle=\langle a, b\rangle$. We now show that $\alpha \otimes \mathrm{K}(\sqrt{f})=0$. Let $\mathrm{L}=\mathrm{K}(\sqrt{f})$ and $k^{\prime}$ be the field of constants of L. Let $\mathrm{X}^{\prime}$ be a smooth, projective, irreducible curve over $k^{\prime}$ with $k^{\prime}\left(\mathrm{X}^{\prime}\right)=\mathrm{L}$. Let $\mathscr{X}^{\prime}$ be a regular proper model of $\mathrm{X}^{\prime}$ over $\mathscr{O}_{k^{\prime}}$ and $y \in \mathscr{X}^{\prime}$ be a point of codimension one. Let $\mathrm{S}=\mathcal{O}_{\mathscr{X}}{ }^{\prime}, \mathscr{y}$ be the discrete valuation ring at $y$. As in the proof of (3.9), it is enough to show that $\alpha_{\mathrm{L}}$ is unramified at S . Since $\mathscr{X}$ is projective over $\mathscr{O}_{k}$, there exists a point $z \in \mathscr{X}$ of codimension 1 or 2 , such that S dominates the local ring $\mathrm{A}=\mathscr{O}_{\mathscr{X}, z}$.

Suppose $\operatorname{dim}(A)=1$. Then $A$ is a discrete valuation ring. Suppose that $z$ does not correspond to a component of C or E . Then $\alpha$ is unramified at A and hence $\alpha_{\mathrm{L}}$ is unramified at S . Let $z$ correspond to a component $\mathrm{C}_{1}$ of C . The case where $z$ corresponds to a component of E is similar.

Suppose that $\mathrm{C}_{1} \cap \mathrm{E}=\emptyset$. Then by (4.3), $\alpha_{\mathrm{L}}$ is unramified at S .
Suppose that $\mathrm{C}_{1} \cap \mathrm{E} \neq \emptyset$. Let $\pi$ be a prime element of B corresponding to the component $\mathrm{C}_{1}$. Since $c, a^{\prime}, b^{\prime}$ are pairwise coprime in B , it follows that at most one of $c, a^{\prime}, b^{\prime}$ is divisible by $\pi$.

Suppose $\pi$ divides $c$. Let $x \in \mathrm{C}_{1} \cap \mathrm{E}$. Then by (i), $a^{\prime} u^{2}+b^{\prime} v^{2}$ is a unit in $\mathscr{O}_{\mathscr{C}, x}$. Since A is a localisation of $\mathscr{O}_{\mathscr{C}, x}, a^{\prime} u^{2}+b^{\prime} v^{2}$ is a unit in A. Further, since $\pi$ divides $c$, both $a^{\prime}$ and $b^{\prime}$ are units in A. Therefore $f$ is a parameter in A and hence by (4.3), $\alpha_{\mathrm{L}}$ is unramified at S .

Suppose $\pi$ does not divide $c$ and divides $a^{\prime}$ or $b^{\prime}$. Let $x \in \mathrm{C}_{1} \cap \mathrm{E}$. If $c(x)=0$, then by (i), $a^{\prime} u^{2}+b^{\prime} v^{2}$ is a unit at $x$ and hence it is a unit in A. If $c(x) \neq 0$, then by (ii), $u$ and $v$ are units at $x$ and hence units in A. Since only one of the $a^{\prime}, b^{\prime}$ is divisible by $\pi, a^{\prime} u^{2}+b^{\prime} v^{2}$ is a unit in A. Therefore, as above, $f$ is a parameter in A and $\alpha_{\mathrm{L}}$ is unramified at S .

Suppose that $\pi$ does not divide $c a^{\prime} b^{\prime}$. Let $x \in \mathrm{C}_{1} \cap \mathrm{E}$. If $c(x)=0$, then by (i), $a^{\prime} u^{2}+b^{\prime} v^{2}$ is a unit at $x$ and hence a unit in A. Suppose that $c(x) \neq 0$. Since $\pi$ does not divide $a^{\prime} b^{\prime}$, the only prime elements of $\mathbf{B}_{m_{x}}$ which divide $a^{\prime} b^{\prime}$ being $\pi$ and $\delta_{x}$, either $a^{\prime}(x) \neq 0$ or $b^{\prime}(x) \neq 0$. Therefore if $a^{\prime} b^{\prime}(x)=0$, then by (ii), $a^{\prime} u^{2}+b^{\prime} v^{2}$ is a unit at $x$ and if $a^{\prime} b^{\prime}(x) \neq 0$, then by iii), $a^{\prime} u^{2}+b^{\prime} v^{2}$ is a unit at $x$. Therefore $a^{\prime} u^{2}+b^{\prime} v^{2}$ is a unit in A and hence $v_{\bar{\delta}_{x}}(\bar{f})=v_{\bar{\delta}_{x}}\left(\overline{c a^{\prime} b^{\prime}}\right)$, which is equal to 0 or 1 . Further, if $v_{\bar{\delta}_{x}}(\bar{f})=0$, by (iii), $f(x)$ is not a square in $\kappa(x)$. Therefore, by (4.3), $\alpha_{L}$ is unramified at S .

Suppose $\operatorname{dim}(\mathbf{A})=2$. Then $z$ is a closed point of $\mathscr{K}$. If $z \notin \mathrm{C} \cup \mathrm{E}$, then $\alpha$ is unramified on A and hence unramified at S (3.7). Assume that $z \in \mathrm{C} \cup \mathrm{E}$. If $z \notin \mathrm{C} \cap \mathrm{E}$, then by (3.3 and 3.5), $\alpha_{\mathrm{L}}$ is unramified at S . Suppose that $z \in \mathrm{C} \cap \mathrm{E}$. Then $\mathrm{A}=\mathrm{B}_{m_{z}}$, where $m_{z}$ is the maximal ideal of B at $z$.

Suppose that $c(z)=0$. Then, by the choice of $u, v, a^{\prime} u^{2}+b^{\prime} v^{2}$ is a unit at $z$. Since the only prime elements of A which divide $c a^{\prime} b^{\prime}$ are $\pi_{z}, \delta_{z}$ and $c, a^{\prime}, b^{\prime}$ are pairwise coprime, $f=c a^{\prime} b^{\prime}\left(a^{\prime} u^{2}+b^{\prime} v^{2}\right)$ is of the form $w \pi_{z}$ or $w \boldsymbol{\delta}_{z}$ or $w \pi_{z} \delta_{z}$, with $w \in \mathrm{~A}^{*}$. Since $f \in \mathrm{~L}^{* 2}$, by (3.6), $\alpha_{\mathrm{L}}$ is unramified at S .

Suppose that $c(z) \neq 0$ and $a^{\prime}(z) b^{\prime}(z)=0$. If $a^{\prime}(z)$ or $b^{\prime}(z)$ is not zero, then, as above, one shows that either $\pi_{z}$ or $\delta_{z}$ or $\pi_{z} \delta_{z}$ is as in (3.6, ii) and hence, by (3.6), $\boldsymbol{\alpha}_{\mathrm{L}}$ is unramified at S. Suppose that $a^{\prime}(z)=b^{\prime}(z)=0$. Since the only prime elements of A which divide $a^{\prime}, b^{\prime}$ are $\pi_{z}, \delta_{z}$ and $a^{\prime}, b^{\prime}$ are coprime and non units at $z$, we have $a^{\prime}=w \pi_{z}$ and $b^{\prime}=w^{\prime} \delta_{z}$ or $a^{\prime}=w \delta_{z}$ and $b^{\prime}=w^{\prime} \pi_{z}$ for some $w, w^{\prime} \in \mathrm{A}^{*}$. Consider the case where $a^{\prime}=w \pi_{z}$ and $b^{\prime}=w^{\prime} \delta_{z}$, with $w, w^{\prime} \in \mathrm{A}^{*}$ (the other case being similar). Let $v_{\mathrm{S}}$ denote the valuation at S . Since S dominates A , we have $\mathrm{v}_{\mathrm{S}}\left(a^{\prime}\right) \geqslant 1$ and $v_{\mathrm{S}}\left(b^{\prime}\right) \geqslant 1$. We assume without loss of generality that $\nu_{\mathrm{S}}\left(a^{\prime}\right) \leqslant v_{\mathrm{S}}\left(b^{\prime}\right)$. Then, $b^{\prime} / a^{\prime} \in \mathrm{S}$ and

$$
f=c b^{\prime}\left(u^{2}+\left(\frac{b^{\prime}}{a^{\prime}}\right) v^{2}\right)\left(a^{\prime}\right)^{2} .
$$

Suppose that $\mathrm{v}_{\mathrm{S}}\left(a^{\prime}\right)<\mathrm{v}_{\mathrm{S}}\left(b^{\prime}\right)$. Then $u^{2}+\frac{b^{\prime}}{a^{\prime}} v^{2} \in \mathrm{~S}^{*}$. Since $b^{\prime}=w^{\prime} \boldsymbol{\delta}_{z}, w^{\prime} \in \mathrm{A}^{*}, c \in \mathrm{~A}^{*}$ and $f \in \mathrm{~L}^{* 2}$, it follows that $\boldsymbol{\delta}_{z}$ is as in (3.6, ii) and $\boldsymbol{\alpha}_{\mathrm{L}}$ is unramified at S . Suppose that $v_{\mathrm{S}}\left(a^{\prime}\right)=v_{\mathrm{S}}\left(b^{\prime}\right)$. If $u^{2}+\frac{b^{\prime}}{a^{\prime}} v^{2} \in \mathrm{~S}^{*}$, then $\mathrm{v}_{\mathrm{S}}(f)=v_{\mathrm{S}}\left(b^{\prime}\right)+2 v_{\mathrm{S}}\left(a^{\prime}\right)=3 v_{\mathrm{S}}\left(b^{\prime}\right)$. Since $v_{\mathrm{S}}(f)$ is even, it follows that $v_{\mathrm{S}}\left(a^{\prime}\right)=v_{\mathrm{S}}\left(b^{\prime}\right)$ is even. In particular $v_{\mathrm{S}}\left(\boldsymbol{\pi}_{z}\right)=v_{\mathrm{S}}\left(\boldsymbol{\delta}_{z}\right)$ is even. By (3.3, (ii), we have $\alpha=\alpha^{\prime}+\alpha^{\prime \prime}$, where $\alpha^{\prime}$ is unramified on A and $\alpha^{\prime \prime}$ is a sum of symbols of the type $(\mu) \cdot\left(\mu^{\prime}\right) \cdot\left(\pi_{z}\right),(\mu) \cdot\left(\mu^{\prime}\right) \cdot\left(\delta_{z}\right),(\mu) \cdot\left(\pi_{z}\right) \cdot\left(\delta_{z}\right)$, with $\mu, \mu^{\prime}$ running over A*. Since $\pi_{z}$ and $\delta_{z}$ have even valuations at S , clearly $\alpha_{\mathrm{L}}^{\prime \prime}$ is unramified at S . By (3.7), $\alpha_{\mathrm{L}}^{\prime}$, and hence $\alpha_{\mathrm{L}}$, is unramified at S . Assume that $u^{2}+\frac{b^{\prime}}{a^{\prime}} v^{2}$ is not a unit in S. Let $n=\mathrm{v}_{\mathrm{S}}\left(a^{\prime}\right)=v_{\mathrm{S}}\left(b^{\prime}\right)$. Let $\theta$ be a parameter in S and write $a^{\prime}=w_{1} \theta^{n}, b^{\prime}=w_{2} \theta^{n}$, with $w_{1}, w_{2} \in \mathrm{~S}^{*}$. By (ii), $u, v \in \mathrm{~A}^{*}$. Since $u^{2}+\frac{b^{\prime}}{a^{\prime}} v^{2}=u^{2}+\frac{w_{2}}{w_{1}} v^{2}$ is not a unit in S , we have

$$
\frac{\bar{u}^{2}}{\bar{v}^{2}}=-\frac{\overline{w_{2}}}{\overline{w_{1}}} .
$$

By 3.3, (ii), we have $\alpha=\alpha^{\prime}+\alpha^{\prime \prime}$, where $\alpha^{\prime}$ is unramified on A and $\alpha^{\prime \prime}$ is a sum of symbols of the type $(\mu) \cdot\left(\mu^{\prime}\right) \cdot\left(\pi_{z}\right),(\mu) \cdot\left(\mu^{\prime}\right) \cdot\left(\delta_{z}\right),(\mu) \cdot\left(\pi_{z}\right) \cdot\left(\delta_{z}\right)$, with $\mu, \mu^{\prime}$ running over

A*. By (3.5), $(\mu) \cdot\left(\mu^{\prime}\right) \cdot\left(\pi_{z}\right)$ and $(\mu) \cdot\left(\mu^{\prime}\right) \cdot\left(\delta_{z}\right)$ are unramified at S. Since $a^{\prime}=w \pi_{z}=w_{1} \theta^{n}$, $b^{\prime}=w^{\prime} \delta_{z}=w_{2} \theta^{n}$, we have

$$
(\boldsymbol{\mu}) \cdot\left(\boldsymbol{\pi}_{z}\right) \cdot\left(\boldsymbol{\delta}_{z}\right)=(\boldsymbol{\mu}) \cdot\left(w w_{1} \theta^{n}\right) \cdot\left(w^{\prime} w_{2} \theta^{n}\right) .
$$

If $n$ is even, then clearly $(\mu) \cdot\left(\pi_{z}\right) \cdot\left(\boldsymbol{\delta}_{z}\right)$ is unramified at S . Assume that $n$ is odd. Then, we have

$$
(\mu) \cdot\left(\pi_{z}\right) \cdot\left(\delta_{z}\right)=(\mu) \cdot\left(w w_{1} \theta\right) \cdot\left(w^{\prime} w_{2} \theta\right)=(\mu) \cdot\left(w w_{1} \theta\right) \cdot\left(-w w_{1} w^{\prime} w_{2}\right)
$$

and

$$
\left.\partial_{\mathrm{S}}\left((\boldsymbol{\mu}) \cdot\left(\boldsymbol{\pi}_{z}\right) \cdot\left(\boldsymbol{\delta}_{z}\right)\right)_{\mathrm{L}}\right)=(\overline{\boldsymbol{\mu}}) \cdot\left(-\overline{w w_{1} w^{\prime} w_{2}}\right) .
$$

Since $-\overline{w_{2}} / \overline{w_{1}}$ is a square in the residue field of $S$, we have $\partial_{L}\left((\boldsymbol{\mu}) \cdot\left(\boldsymbol{\pi}_{z}\right) \cdot\left(\boldsymbol{\delta}_{z}\right)\right)=(\overline{\boldsymbol{\mu}}) \cdot\left(\overline{w w^{\prime}}\right)$. Since $\mu, w, w^{\prime} \in A^{*}$ and $\kappa(z)$ is a finite field, it follows that $(\bar{\mu}) \cdot\left(\overline{w w^{\prime}}\right)=0$. Hence $\alpha_{L}$ is unramified at S .

Suppose that $c(z) a^{\prime}(z) b^{\prime}(z) \neq 0$. Then by the choice of $u, v$ it follows that $f(z) \notin \kappa(z)^{* 2}$. Since $f$ is a square in S , it follows from (3.6) that $\alpha_{\mathrm{L}}$ is unramified at S . This completes the proof of the proposition.

Theorem 4.5. - Let $k$ be a non-dyadic p-adic field and K a function field in one variable over $k$. Then every quadratic form over K of rank at least 11 is isotropic.

Proof. - Let $q$ be a quadratic form over K of rank 11. Then by a theorem of Saltman (cf. 2.2) $c(q)$ is a biquaternion algebra. Let $q_{0}$ be a quadratic form over K with $\mathrm{rk}\left(q_{0}\right)=5, d\left(q+q_{0}\right)=1$ and $c\left(q+q_{0}\right)=0$ (cf. [HV], 3.2). Then $q+q_{0} \in \mathrm{I}^{3}(\mathrm{~K})$ ([M]). Therefore, by (4.1), there exists a 3-fold Pfister form $q_{1}$ over K such that $q=q_{1}-q_{0}$. Since for any $\lambda \in \mathrm{K}^{*}, q$ is isotropic if and only if $\lambda q$ is isotropic, we assume that $q_{0}=<1, a, b, c, d>$ for some $a, b, c, d \in \mathrm{~K}^{*}$. Let $\alpha=e_{3}\left(q_{1}\right)$. Then by (4.4), there exists $f \in \mathbf{K}^{*}$ which is a value of $\langle-a,-b\rangle$ such that $\alpha \otimes \mathbf{K}(\sqrt{f})=0$. Since $e_{3}$ is an isomorphism, $q_{1} \otimes \mathrm{~K}(\sqrt{f})$ is hyperbolic. Therefore there exist $g, h \in \mathbf{K}^{*}$ such that $q_{1}=<1,-f><1, g><1, h>$. Since $-f$ is a value of $<a, b>$, there exists $f^{\prime} \in \mathrm{K}^{*}$ such that $<a, b>\simeq<-f, f^{\prime}>$. We have

$$
\begin{aligned}
q & =q_{1}-q_{0} \\
& =<1,-f><1, g><1, h>-<1,-f, f^{\prime}, c, d> \\
& =<1,-f><g, h, g h>-<f^{\prime}, c, d>
\end{aligned}
$$

Since $\mathrm{rk}(q)=11$ and the rank of $<1, f><g, h, g h>-<f^{\prime}, c, d>$ is 9 , it follows that $q$ is isotropic over K.

Theorem 4.6. - Let $k$ be a non-dyadic p-adic field and K a function field in one variable over $k$. Let $q$ be a quadratic form over K of rank at least 9. Suppose that $c(q)$ is of index at most 2. Then $q$ is isotropic.

Proof. - By (4.5), if the rank of $q$ is at least 11 , then $q$ is isotropic. Assume that rank of $q$ is 9 or 10 . Since $c(q)$ is of index at most 2 , there exist $a, b \in \mathrm{~K}^{*}$ such that $c(q)=(-a) \cdot(-b)$ in $\mathrm{H}^{2}(\mathbf{K}, \mathbf{Z} / 2)$. Suppose that the rank of $q$ is 9 . By scaling, we can assume that $d(q)=1$. Let $q_{0}=\langle a, b, a b\rangle$. Then $d\left(q-q_{0}\right)=1$ and $c\left(q-q_{0}\right)=0$. Therefore $q=q_{0}+q_{1}$ for some $q_{1} \in \mathrm{I}^{3}(\mathbf{K})$. As in the proof of (4.5), there exists $f \in \mathrm{~K}^{*}$ which is a value of $\langle a, b\rangle$ and $q_{1} \otimes \mathrm{~K}(\sqrt{-f})$ is hyperbolic. Therefore we have $<a, b>=<f, f^{\prime}>$ and $q_{1}=<1, f><1, g><1, h>$ for some $f^{\prime}, g, h \in \mathbf{K}^{*}$. Since $\mathrm{I}^{4}(\mathrm{~K})=0$ and $q_{1} \in \mathrm{I}^{3}(\mathrm{~K})$, we have $\lambda q_{1}=q_{1}$ for every $\lambda \in \mathrm{K}^{*}$. Thus, we have

$$
\begin{aligned}
(-a b) q & =(-a b) q_{0}+(-a b) q_{1} \\
& =(-a b) q_{0}+q_{1} \\
& =<-b,-a,-1>+q_{1} \\
& \left.=<-f,-f^{\prime},-1>+<1, f\right\rangle+\langle 1, f\rangle<g, h, g h> \\
& =<-f^{\prime}>+<1, f><g, h, g h>.
\end{aligned}
$$

Therefore $q$ is isotropic. Suppose that the rank of $q$ is 10 . Let $q^{\prime}=q \perp<1>$. Then $c(q)=c\left(q^{\prime}\right)$. Since the rank of $q^{\prime}$ is 11 , it is isotropic by (4.5). Write $q^{\prime}=<1,-1>\perp q^{\prime \prime}$. Then the rank of $q^{\prime \prime}$ is 9 and $c\left(q^{\prime \prime}\right)=c\left(q^{\prime}\right)=c(q)$. Therefore $q^{\prime \prime}$ is isotropic. Since $q=q^{\prime \prime} \perp<-1>, q$ is isotropic.

## 5. Zero-cycles on quadric fibrations

Let $k$ be a $p$-adic field and C a smooth, projective, geometrically integral curve over $k$. Let $\pi: \mathrm{X} \rightarrow \mathrm{C}$ be an admissible quadric fibration over C (cf. [CSk], §3). For a variety Y , let $\mathrm{CH}_{0}(\mathrm{Y})$ denote the Chow group of zero-cycles on Y. Let $\pi_{*}: \mathrm{CH}_{0}(\mathrm{X}) \rightarrow \mathrm{CH}_{0}(\mathrm{C})$ be the induced homomorphism and $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})=\operatorname{ker}\left(\pi_{*}\right)$. If $\operatorname{dim}(\mathrm{X})=2$, then it was proved in ([G]) that the group $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})$ is finite. In ([CSk]), Colliot-Thélène and Skorobogatov proved that if $\operatorname{dim}(\mathrm{X})=3$, then $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})$ is finite and they raised the following question:
If $\operatorname{dim}(\mathrm{X}) \geqslant 4$, is the group $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})$ zero or at least finite?
In ([PS], 4.8), it was shown that the group $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})$ is finite, answering the latter part of the above question. Recently Hoffmann and Van Geel ([HV], 4.2) proved that if $k$ is non-dyadic and $\operatorname{dim}(\mathrm{X}) \geqslant 6$, then $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})=0$. Using results proved in $\S 4$, we show that $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})=0$ if $\operatorname{dim}(\mathrm{X}) \geqslant 4$ and $k$ is a non-dyadic $p$-adic field.

We recall the identification of $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})$ with a certain subquotient of $k(\mathrm{C})^{*}$ given in ([CSk], 4.2). Let $k$ be a field of characteristic not equal to 2 and C a smooth, projective, geometrically integral curve over $k$. Let $\pi: \mathrm{X} \rightarrow \mathrm{C}$ be an admissible quadric fibration of relative dimension at least 1 . Let $q$ be a quadratic form over $k(\mathrm{C})$ defining the generic fibre of $\pi$. Let $\mathrm{N}_{q}(k(\mathrm{C}))$ be the subgroup of $k(\mathrm{C})^{*}$ generated by elements of the type $a b$ with $a, b \in k(\mathrm{C})^{*}$, which are values of $q$ over $k(\mathrm{C})$. Let $k(\mathrm{C})_{\mathrm{dn}}^{*}$ be the subgroup of $k(\mathrm{C})^{*}$ consisting of functions, which, at each closed point P of C , can be
written as a product of a unit at P and an element of $\mathrm{N}_{q}(k(\mathrm{C}))$. We recall the following result from ([CSk], 4.2).

Proposition 5.1. - There is an isomorphism

$$
\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C}) \xrightarrow{\sim} k(\mathrm{C})_{\mathrm{dn}}^{*} / k^{*} \mathrm{~N}_{q}(k(\mathrm{C}))
$$

Theorem 5.2. - Let $k$ be a non-dyadic p-adic field and C a smooth, projective, geometrically integral curve over $k$. Let $\pi: \mathrm{X} \rightarrow \mathrm{C}$ be an admissible quadric fibration. If $\operatorname{dim}(\mathrm{X}) \geqslant 4$, then $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})=0$.

Proof. - Let $q$ be a quadratic form over $k(\mathbf{C})$ defining the generic fibre of $\pi$. Since $\operatorname{dim}(\mathrm{X}) \geqslant 4$, the rank of $q$ is at least 5 . If $q$ is isotropic, then every element in $k(\mathrm{C})^{*}$ is represented by $q$ over $k(\mathrm{C})$ and hence $\mathrm{N}_{q}(k(\mathrm{C}))=k(\mathrm{C})^{*}$. Assume that $q$ is anisotropic over $k(\mathrm{C})$. Let $f \in k(\mathrm{C})^{*}$. Since $q \otimes<1,-f>\otimes k(\mathrm{C})(\sqrt{f})$ is hyperbolic, $c(q \otimes<1,-f>) \otimes k(\mathbf{C})(\sqrt{f})$ is zero and hence the index of $c(q \otimes<1,-f>)$ is at most 2. Therefore by (4.6), $\langle 1,-f\rangle \otimes q$ is isotropic. That is, there exist $v, w$ in the underlying vector space of $q$, with at least one of them non-zero such that $q(v)-f q(w)=0$. Since $q$ is anisotropic, $q(v) q(w) \neq 0$. Therefore $f=q(v) q(w)^{-1} \in \mathrm{~N}_{q}(k(\mathbf{C}))$ and hence $\mathrm{N}_{q}(k(\mathrm{C}))=k(\mathrm{C})^{*}$. By (5.1), it follows that $\mathrm{CH}_{0}(\mathrm{X} / \mathrm{C})=0$.

## 6. Cayley algebras

In this section, we recall a connection between $H_{d e c}^{3}(\mathbb{K})$ and the set of isomorphism classes of Cayley algebras over a field K of characteristic not 2 ([Se], §8.3). We then give a description of the set of isomorphism classes of Cayley algebras over function fields of non-dyadic $p$-adic curves in the spirit of Serre, using the fact that $H_{\text {dec }}^{3}(K)=H^{3}(K)$ and a theorem of Kato.

Theorem 6.1 ([Se], §8, Theorem 9). - Let G be a split algebraic group of type $\mathrm{G}_{2}$ defined over a field K of characteristic not equal to 2 . There are canonical bijections between the following sets:
(i) $\mathrm{H}^{1}(\mathrm{~K}, \mathrm{G})$.
(ii) $\mathbf{H}_{\mathrm{dec}}^{3}(\mathbf{K})=\left\{\alpha \in \mathrm{H}^{3}(\mathbf{K}, \mathbf{Z} / 2), \alpha=(a) \cdot(b) \cdot(c), a, b, c \in \mathrm{~K}^{*}\right\}$.
(iii) The set of isomorphism classes of K -forms of $G$.
(iv) The set of isomorphism classes of Cayley algebras over K .
(v) The set of isomorphism classes of 3-fold Pfister forms.

Let $k$ be a $p$-adic field. Let P be the set of closed points of $\mathbf{P}_{k}^{1}$ and

$$
\mathrm{C}(\mathbf{P})=\left\{f: \mathbf{P} \rightarrow \mathbf{Z} / 2 \mid \operatorname{Supp}(f) \text { finite and } \sum_{x \in \mathrm{P}} f(x)=0\right\}:
$$

The exact sequence

$$
0 \rightarrow \mathrm{H}^{3}(k(t), \mathbf{Z} / 2) \rightarrow \bigoplus_{x \in \mathbf{P}} \mathrm{H}^{2}(\boldsymbol{\kappa}(x), \mathbf{Z} / 2) \rightarrow \mathrm{H}^{2}(k, \mathbf{Z} / 2) \rightarrow 0
$$

identifies $\mathrm{H}^{3}(k(t), \mathbf{Z} / 2)$ with $\mathrm{C}(\mathrm{P})$, noting that $\mathrm{H}^{2}(\mathbf{\kappa}(x), \mathbf{Z} / 2)=\mathbf{Z} / 2$ for every $x \in \mathbf{P}$ and the map $\oplus_{x \in \mathrm{P}} \mathrm{H}^{2}(\mathbf{k}(x), \mathbf{Z} / 2) \rightarrow \mathrm{H}^{2}(k, \mathbf{Z} / 2)$ is the addition. In ([Se], §8.3), Serre raises the question whether $\mathrm{H}^{1}(k(t), \mathrm{G})$ is in bijection with $\mathrm{C}(\mathrm{P})$. This is equivalent to the question whether $H_{\text {dec }}^{3}(k(t))=\mathrm{H}^{3}(k(t), \mathbf{Z} / 2)$. In view of (3.9), this is indeed true if $k$ is non-dyadic.

Let $k$ be a non-dyadic $p$-adic field, and X a smooth, projective, integral curve over $k$. Using a result of Kato ( $[\mathrm{K}]$ ) and following Serre, we give a description of $\mathrm{H}^{1}(k(\mathrm{X}), \mathrm{G})$ as follows. Let $\mathscr{X}$ be a regular, proper model of X over $\mathscr{O}_{k}$. Let $\mathrm{Y}=\mathscr{B} \times_{\operatorname{Spec}\left(\mathcal{O}_{k}\right)} \operatorname{Spec}\left(\mathbf{F}_{q}\right)$ be the special fibre, where $\mathbf{F}_{q}$ is the residue field of $k$. Let $\mathrm{Y}^{\prime}$ be the reduced scheme of Y and $\pi: \widetilde{\mathrm{Y}} \rightarrow \mathrm{Y}^{\prime}$ be the normalisation of $\mathrm{Y}^{\prime}$. Let $\mathrm{Y}_{\text {sing }}^{\prime}$ denote the set of singular points of $\mathrm{Y}^{\prime}$ and $\mathrm{Q}=\pi^{-1}\left(\mathrm{Y}_{\text {sing }}^{\prime}\right)$. Let $\widetilde{\mathrm{Y}}=\cup_{1}^{\gamma} \bar{\Psi}_{i}, \quad \widetilde{Y}_{i}$ denoting the irreducible components of $\widetilde{\mathrm{Y}}$. Let

$$
\mathrm{C}(\mathbf{Q})=\left\{f: \mathbf{Q} \rightarrow \mathbf{Z} / 2 \mid \sum_{x \in \mathbb{Y}_{\mathrm{i}} \cap \mathrm{Q}} f(x)=0,1 \leqslant i \leqslant r, \sum_{x \in \pi^{-1}(\mathscr{Y})} f(x)=0 \text { for all } y \in \mathrm{Y}_{\text {sing }}^{\prime}\right\} .
$$

For $y \in \mathbf{Y}^{1}$, let

$$
\partial_{i}^{y}: \mathrm{H}^{2}\left(\mathbf{k}\left(\widetilde{\mathrm{Y}}_{i}\right), \mathbf{Z} / 2\right) \rightarrow \mathrm{H}^{1}(\mathbf{k}(y), \mathbf{Z} / 2)
$$

be the homomorphism defined as $\partial_{i}^{y}=0$ if $\pi^{-1}(y) \cap \widetilde{Y}_{i}=\emptyset$ and otherwise

$$
\partial_{i}^{y}=\sum_{\tilde{y} \in \pi^{-1}(\mathcal{y}) \cap \tilde{\mathrm{Y}}_{i}} \partial_{i}^{\tilde{y}}
$$

where $\partial_{i}^{\tilde{y}}$ denotes the residue map at $\tilde{y}$. Let

$$
\partial^{y}=\sum_{i} \partial_{i}^{y}
$$

By a result of Kato ([K], 5.2), we have an isomorphism

$$
\mathrm{H}_{\mathrm{nr}}^{3}(k(\mathrm{X}) / \mathrm{X}, \mathbf{Z} / 2) \xrightarrow{\sim} \operatorname{ker}\left(\bigoplus_{i} \mathrm{H}^{2}\left(\mathbf{k}\left(\widetilde{\mathrm{Y}}_{i}\right), \mathbf{Z} / 2\right) \xrightarrow{\partial=\left(\partial^{\prime}\right)} \underset{y \in \mathrm{Y}^{1}}{\bigoplus} \mathrm{H}^{1}(\mathbf{k}(y), \mathbf{Z} / 2)\right) .
$$

Lemma 6.2. - We have an isomorphism

$$
\operatorname{ker}\left(\bigoplus_{i} \mathrm{H}^{2}\left(\mathbf{k}\left(\widetilde{\mathrm{Y}}_{i}\right), \mathbf{Z} / 2\right) \xrightarrow{\partial} \bigoplus_{y \in \mathrm{Y}^{1}} \mathrm{H}^{1}(\mathbf{\kappa}(y), \mathbf{Z} / 2)\right) \simeq \mathrm{C}(\mathbf{Q})
$$

Proof. - Let $\left(\boldsymbol{\alpha}_{i}\right) \in \oplus_{i} \mathrm{H}^{2}\left(\boldsymbol{\kappa}\left(\widetilde{Y}_{i}\right), \mathbf{Z} / 2\right)$ be such that $\partial\left(\left(\boldsymbol{\alpha}_{i}\right)\right)=0$. Then for a closed point $\tilde{y} \in \widetilde{\mathbf{Y}}_{i} \backslash Q \partial_{i}^{\tilde{y}}\left(\boldsymbol{\alpha}_{i}\right)=0$. For $\tilde{y} \in \mathbf{Q} \cap \widetilde{\mathrm{Y}}_{i}$, let $f(\tilde{y})=\partial_{i}^{\tilde{y}}\left(\boldsymbol{\alpha}_{i}\right) \in \mathbf{H}^{1}(\kappa \mathbf{\kappa}(\tilde{y}), \mathbf{Z} / 2)=\mathbf{Z} / 2$. Then, by class field theory for function fields in one variable over finite fields, it follows that $f \in \mathrm{C}(\mathrm{Q})$. Conversely, let $f \in \mathrm{C}(\mathrm{Q})$. Then by class field theory, there exist $\boldsymbol{\alpha}_{i} \in \mathrm{H}^{2}\left(\boldsymbol{\kappa}\left(\widetilde{\mathrm{Y}}_{i}\right), \mathbf{Z} / 2\right)$ such that for $\tilde{y} \in \mathrm{Q} \cap \widetilde{\mathrm{Y}}_{i}, \partial_{i}^{\tilde{\prime}}\left(\boldsymbol{\alpha}_{i}\right)=f(\tilde{y})$ and if $\tilde{y} \in \cup \widetilde{\mathrm{Y}}_{i} \backslash \mathbf{Q}$, then $\partial_{i}^{\tilde{n}}\left(\boldsymbol{\alpha}_{i}\right)=0$ for all $i$. Since $f \in \mathrm{C}(\mathbf{Q}), \partial\left(\boldsymbol{\alpha}_{i}\right)=0$. This proves the lemma.

Let P be the set of closed points of X . Let

$$
\mathrm{C}(\mathrm{P})=\left\{f: \mathrm{P} \rightarrow \mathbf{Z} / 2 \mid \operatorname{Supp}(f) \text { finite and } \sum_{x \in \mathrm{P}} f(x)=0\right\} .
$$

We have an exact sequence ( $[\mathrm{K}], 5.2$ )

$$
0 \rightarrow \mathrm{H}_{\mathrm{nr}}^{3}(k(\mathrm{X}) / \mathrm{X}, \mathbf{Z} / 2) \rightarrow \mathrm{H}^{3}(k(\mathrm{X}), \mathbf{Z} / 2) \rightarrow \bigoplus_{x \in \mathrm{P}} \mathrm{H}^{2}(\kappa(x), \mathbf{Z} / 2) \rightarrow \mathbf{Z} / 2 \rightarrow 0
$$

This sequence induces an exact sequence

$$
0 \rightarrow \mathrm{H}_{\mathrm{nr}}^{3}(k(\mathrm{X}) / \mathrm{X}, \mathbf{Z} / 2) \rightarrow \mathrm{H}^{3}(k(\mathbf{X}), \mathbf{Z} / 2) \rightarrow \mathrm{C}(\mathbf{P}) \rightarrow 0
$$

By (6.2), we have $\mathrm{H}_{\mathrm{nr}}^{3}(k(\mathbf{X}) / \mathrm{X}, \mathbf{Z} / 2) \simeq \mathrm{C}(\mathbf{Q})$. In view of (3.9), we have $\mathrm{H}_{\mathrm{dec}}^{3}(k(\mathbf{X}), \mathbf{Z} / 2)=$ $\mathrm{H}^{3}(k(\mathrm{X}), \mathbf{Z} / 2)$ and we have the following

Theorem 6.3. - Let $k$ be a non-dyadic p-adic field and X a smooth, projective, irreducible curve over $k$. The bïection $\mathrm{H}^{1}(k(\mathbf{X}), \mathrm{G}) \simeq \mathrm{H}_{\text {dec }}^{3}(k(\mathbf{X}), \mathbf{Z} / 2)=\mathrm{H}^{3}(k(\mathbf{X}), \mathbf{Z} / 2)$ makes $\mathrm{H}^{1}(k(\mathbf{X}), \mathrm{G})$ a $\mathbf{Z} / 2$-vector space which fits into an exact sequence

$$
0 \rightarrow \mathrm{C}(\mathbf{Q}) \rightarrow \mathrm{H}^{1}(k(\mathrm{X}), \mathrm{G}) \rightarrow \mathrm{C}(\mathrm{P}) \rightarrow 0:
$$
