V. Glaser

The Positivity Condition in Momentum Space

Les rencontres physiciens-mathématiciens de Strasbourg - RCP25, 1973, tome 16
« Réédition des conférences les plus demandées contenues dans les volumes épuisés », exp. n° 5, p. 1-36

<http://www.numdam.org/item?id=RCP25_1973__16__A5_0>
A formulation of the positivity condition within the framework of the general field theory is given in momentum space. It is shown how the usual requirements of locality and spectrum can be partially incorporated in order to represent the "absorptive parts" of the Green's functions by positive operators of the Hilbert-Schmidt type operating on a suitably defined Hilbert space of analytic functions introduced into mathematics by Bergman and Bochner. The application of this method to the x space positivity condition formulated by Wightman is not discussed in this paper. As an illustration, two simple examples are discussed in the last Section.
1. INTRODUCTION.

As it is well known, the study of a field theory either in the formulation of Wightman 1) or that of Haag-Araki 2) can be reduced to the study of the set of functions

\[(\Omega, A(x_{\pi_1}) A(x_{\pi_2}) \ldots A(x_{\pi_n}) \Omega), \quad n = 1, 2, 3, \ldots \quad (1.1)\]

where \(A(x_{\pi_i})\) is the field operator attached to the space-time point \(x_{\pi_i}\), \(\pi\) is any permutation of the indices, and \(\Omega\) is the vacuum state 3). All the physical properties imposed on the system can be translated into functional properties of the set of Wightman functions (1.1). Thus, invariance under space-time translations, spectral condition and local commutativity entail analyticity of the functions in a certain "primitive" domain of the complexified variables \(x_{\pi_i} - x_{\pi_j}\). The search for a representation that would embody automatically these three properties constitutes the so-called "linear program".

The "positivity condition" which has to be added to these linear properties, expresses the fact that the set (1.1) is a positive functional on the algebra of field operators, i.e., that these functions are matrix elements of operators in a Hilbert space with positive metric. This condition, which interconnects different Wightman functions, was first explicitly stated and investigated by Wightman himself.

In their approach to field theory, Bogoliubov and his co-workers 3) lay, however, stress on the \(S\) matrix as the fundamental physical quantity - the fields appear rather as a response of particles to external perturbations:

\[(\Box - m^2) A(x) \equiv j(x) = \sum_{i} \frac{8}{8A_{\text{in}}(x)} S \quad (1.2)\]

and the locality condition as a causal propagation of these perturbations:

*) Only the case of a single neutral scalar field will be discussed in this paper.
\[
\frac{1}{i} \frac{\delta A_{in}(x_1)}{\delta \gamma} \cdots \frac{1}{i} \frac{\delta A_{in}(x_{n-1})}{\delta \gamma} A(x_n) = R(x_1, \ldots, x_{n-1} ; x_n) = 0 \quad (1.3)
\]

unless \( x_n - x_i \in \bar{V}_+ \), \( i = 1, 2, \ldots, n - 1 \)

where \( \bar{V}_+ \) denotes the future light-cone. The study of the vacuum expectation values of "Wightman products" \( A(x_1) \cdots A(x_n) \) can be replaced by that of retarded functions:

\[
(\Omega, R^i_n(x)\Omega) = r^i_n(x), \quad R^i_n(x) = R(x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_n ; x_i) \quad (1.4)
\]

which have now analyticity properties in momentum space in view of the support properties (1.3) in \( x \) space. The positivity condition is replaced by a stronger one which is a generalization of the unitary condition \( S^*S = 1 \) and which includes also the L.S.Z. reduction formulae \(^4\) and the assumption of the completeness of the asymptotic states. From the set of functions (1.4) satisfying these conditions one also can reconstruct the field (1.2) having all the required properties \(^5\). This approach, although less general, has the advantage of being more closely connected to the physically observable scattering amplitudes.

The purpose of this article is to formulate the positivity condition in the second framework and to study its connection with analyticity properties of the off and on mass-shell scattering amplitudes in momentum space. The incentive for this investigation were the papers by Martin \(^6\) in which he showed the interplay of analyticity and positivity leads to an enlargement of the domain of analyticity of the four-point scattering amplitude in the framework of general field theory. As the reader will notice, the positivity condition in momentum space takes a slightly different form than the corresponding one in \( x \) space and resembles very much to the theory of Bergman \(^7\) kernels for Hilbert spaces of functions analytic in a given domain in \( \mathbb{C}_N \) \(^8\). The method of Hilbert spaces of analytic functions developed here can be also applied to the set of Wightman functions in \( x \) space, but that case will not be considered in this paper.
Next Section will very briefly remind the reader of some properties of the generalized retarded functions and state the positivity condition. Section 3 will discuss the "continuation" of the positivity condition into the complex domain in several different forms. It contains the main substance of this paper. In the final Section we will try to illustrate the usefulness of the general concepts by rederiving a very well-known positivity property of the absorptive part of the scattering amplitude used repeatedly by Martin in 6).

2. THE POSITIVITY CONDITION.

The retarded functions (1.4) have the following formal expression

\[ r(x_2, \ldots, x_n ; x_1) = (\Box - m^2) \ldots (\Box - m^2) \sum_{\pi} \theta(x_1^0 - x_{n2}^0) \ldots \]  

\[ \theta(x_{n(n-1)}^0 - x_{n1}^0)(\Omega , [\ldots[A(x_1), A(x_2)] \ldots A(x_{nn})] \Omega) \]

where \( \Box - m^2 \) is the Klein-Gordon operator referring to the variables \( x_i = (x_i^0, x_i^\perp) \), \( \theta(t) \) is the usual step function and the square brackets indicate commutators. It is still unknown whether starting from the Wightman axioms, these formal expressions for \( n > 3 \) have a sense as tempered distributions satisfying the same algebraic relations, support properties, etc., as they would do if the Wightman functions were genuine functions *) .

In the LSZ formalism they are assumed to do so. However, by replacing in (1.1) the "sharp" fields \( A(x) \) by smeared out fields \( A_f(x) = (A * f)(x) \), \( f \in \mathcal{D}(\mathbb{R}^4) \) (infinitely differentiable functions having compact support) or even by local observables attached to finite space-time regions as proposed by Haag and Araki 12), the just mentioned difficulty can be avoided. Moreover, the reduction formulae can be then deduced in a rigorous way from the Wightman

*) This problem is a generalization of the problem of renormalization in perturbation theory, and was studied especially by Steinmann 10). The problem for \( n = 2 \) is trivial, the case \( n = 3 \) was solved by Stora 11).
or Haag-Araki axioms, as shown by Hepp 12) *). Also the analyticity properties remain unaltered by this "smearing out" since the support of (1.3) gets only shifted by a finite amount. We will, therefore, place ourselves in what follows indifferently in any of the schemes just described.

Although, as already mentioned, the set of retarded functions (1.4) [or the set of advanced functions obtained by substituting the step function \( \theta_-(t) = \theta(-t) \) for \( \theta(t) \) in the expression (2.1)] is rich enough to reconstruct the field operators themselves by making use also of the uniterity relations, it was recognized by Steinmann 14) that in order to exploit completely the linear properties of the \( n \) point function a more general set of "retarded" products had to be introduced. In the Bogoliubov formalism they can be described as generated from the field \( A(x) \) by taking functional derivatives with respect to the \( A_{in} \) and \( A_{out} \) fields in all possible combinations and permutations [compare (1.3)]. They can also be defined as a linear combination of multiplied by suitable step functions [compare (1.1)] **). For our purposes the following qualitative remarks will do.

Let us denote by \( R^i_n(x) \) the generalized retarded product of \( n \) fields, and by \( r^i_n(x) \) the corresponding vacuum expectation values. The functions (distributions) \( r^i_n \) depend only on the differences \( x_i - x_j \) of their arguments and have supports in certain cones \( C^i_n \). Consequently, their Fourier transforms \( \tilde{r}^i_n(p) \) defined by

\[
\tilde{r}^i_n(p) = (2\pi)^{-n} \int \delta_4(p_1 + \ldots + p_n) \tilde{r}^i_n(p) e^{-ipx} dp
\]

*) As in Ruelle's 13) proof of the existence of the \( S \) matrix, one has to suppose here that the energy has a finite gap above the vacuum state and that the asymptotic states are complete in the underlying Hilbert space.

**) A detailed study of the different and somewhat involved properties of the generalized retarded functions, which in some way reflect the rather complicated kinematics of the \( n \) body problem, was done also by Ruelle 15), Araki 16), Araki and Burgoyne 17 and Bros 18). For a recommended review article, see 19).
where
\[ p = p_1 x_1 + \cdots + p_n x_n \quad , \quad dp = d^4 p_1 \cdots d^4 p_n \]
are boundary values (in the sense of distributions) of functions \( \tilde{r}_n^i(k) \),
\( k = p + iq \) analytic in the tubes \( \tau_n^i = \{ k : \text{Im } k = q \in \mathbb{C}_n^i \} \) (\( \mathbb{C}_n^i \) is the dual cone of the cone \( C_n^i \)). This analyticity is an expression of the locality of the theory. The spectral condition finds its expression in the coincidence of all the boundary values \( \tilde{r}_n(p) = \tilde{r}_n^{j}(p) \) (n fixed !) in a certain region \( p \in \mathbb{R}^n_m \) of the real momentum space \( \mathbb{R}^{4(n-1)} \) depending on the masses of the particles described by the theory. From the edge of the wedge theorem \( 3), 20 \), it follows then that all the functions \( \tilde{r}_n(p) \) are different boundary values of one and the same function \( \tilde{r}_n(k) \) analytic in the envelope of holomorphy of the domain \( \mathbb{U} \mathbb{C}_n^i \cup [\mathbb{R}^n_m] \), where \( [\mathbb{R}^n_m] \) is a complex neighbourhood of the region of coincidence \( \mathbb{R}^n_m \). The S matrix elements involving n particles are restrictions of a well chosen function \( \tilde{r}_n(p) \) to the mass shell manifold \( p_j^2 = m^2 \) (j = 1, 2, ..., n), m being the mass of the particles involved.

The analyticity domain of the scattering amplitude is the intersection of the complex mass shell manifold \( k_j^2 = m^2 \) with the domain of holomorphy of the function \( \tilde{r}_n(k) \) (one has proved so far only the case \( n = 4 \) that this intersection is non-empty). We mention also that for each (real) momentum \( p \) there is a function \( \tilde{r}_n(p) \) which coincides in a neighbourhood of that point with the Fourier transform of the truncated vacuum expectation value of the time-ordered product \( T_n \). As a final remark, the generalized retarded functions satisfy some linear identities called the Steinmann relations. We shall mention them later when needed.

After these preliminaries, we are ready to formulate the positivity condition. By denoting
\[ R_n^i(f) = \int R_n^i(x_1, \ldots, x_n) f_n^i(x_1, \ldots, x_n) \, d^4 x_1 \cdots d^4 x_n \] 
(2.2)
where \( f_n^i \) is a test function \( \in \mathcal{S}(\mathbb{R}^n_4) \), (i.e., infinitely differentiable and of fast decrease at infinity), the positivity condition reads:

*) The restriction of a distribution to a manifold makes in general no sense.
It was proved by Hepp in the quoted article \( 12 \) that it does in this case.
for every choice of the $f^i_n$. We suppose here that the sum extends only over a finite number of terms. This condition was first written and studied by Wightman in the case of products of fields. To avoid notational complications we shall study it in the special case of one term instead of the sum. What we will have to say will extend in a straightforward way to the general case (see end of Section 3).

In this simpler case, (2.3) becomes (we drop the indices):

$$\int A(x_1, \ldots, x_{2n}) f(x_1, \ldots, x_n) f(x_{n+1}, \ldots, x_{2n}) \, dx_1 \cdots dx_{2n} = 0$$

for all $f \in \mathcal{O}(B_{2n})$ (2.4)

with $A(x_1, \ldots, x_{2n}) = (\Omega, R^*(x_1, \ldots, x_n) R(x_{n+1}, \ldots, x_{2n}) \Omega)$. 

By going to momentum space, we get

$$\int \delta^2(k_1, \ldots, k_{2n}) \Lambda(x_1, \ldots, x_{2n}) \bar{f}(-k_1, \ldots, -k_n) \bar{f}(k_{n+1}, \ldots, k_{2n}) \, dk_1 \cdots dk_{2n} = 0$$

(2.5)

where we have introduced the Fourier transforms as follows

$$f(x) = \int e^{-i k_1 x_1 - \cdots - i k_n x_n} \Lambda(k) \, dk_1 \cdots dk_n$$

$$\Lambda(x) = (2\pi)^{-2n} \int \delta^2 (k_1, \ldots, k_{2n}) \Lambda(k_1, \ldots, k_{2n}) e^{-i k_1 x_1 - \cdots - i k_{2n} x_{2n}} \, dk_1 \cdots dk_{2n}$$

(2.6)

Let us now introduce the total energy and momentum co-ordinates $\sigma, \sigma'$ and the relative momenta $p_v, q_v$ of the two "clusters" $R^*$ and $R$ by the formula

$$k_v = -\sigma - p_v, \ (v = 1, \ldots, n), \ \sigma = -\sum_{v=1}^{n} k_v, \ \text{with} \ \sum_{v=1}^{n} p_v = 0$$

$$k_{n+v} = -\sigma' + q_v, \ (v = 1, \ldots, n), \ \sigma' = \sum_{v=1}^{n} k_{n+v}, \ \text{with} \ \sum_{v=1}^{n} q_v = 0$$
Then (2.5) takes the following form:

\[ \int A_\sigma(p,q) \varphi(\sigma, p) \varphi(\sigma, q) \, dp \, dq \geq 0 \tag{2.7} \]

where \( A_\sigma(p, q) = A(-\sigma/n - p_1, \ldots, -\sigma/n - p_n, \sigma/n + q_1, \ldots, \sigma/n + q_n) \),

\[ \varphi(\sigma, p) = \tilde{\varphi}(\sigma + p_1, \ldots, \sigma + p_n) \]

and \( dp = dp_1 \ldots dp_{n-1} \), \( dq = dq_1 \ldots dq_{n-1} \).

Since the \( n \) vectors \( p^\nu \) and the \( n \) vectors \( q^\nu \) satisfy the two relations (2.6), we have (arbitrarily) chosen the first \( n-1 \) as linearly independent.

The spectral condition tells us that the function \( A_\sigma \) (tempered distribution more precisely) has its support in \( \sigma \in \overline{V}(M) \) where \( \overline{V}(M) = \{ \sigma : \sigma \geq 0, \sigma^2 \geq M^2 \} \), and \( M \) is the lowest mass of the intermediary states that can be inserted between \( R^* \) and \( R \) in (2.4). Since the Fourier transform of \( (\Omega, R^* R \Omega) \) expressed in the variables (2.6) has, as immediately seen, its support in \( \{ \sigma \in \overline{V}_+(M) = -\overline{V}_+(M) \} \), \( A_\sigma(p, q) \) can also be regarded as the Fourier transform of the commutator

\[ A_\sigma(p, q) = \mathcal{F}(\Omega, [R^*, R] \Omega) \quad \text{for} \quad \sigma \in \overline{V}_+ \tag{2.8} \]

The function \( (\Omega, R^*(x) R(x') \Omega) \) is only partially a retarded function: it has support properties only separately in the variables \( x \) and \( x' \) but none in \( x-x' \). Therefore \( A_\sigma(p, q) \) is the boundary value of a function analytic in \( p \) and \( q \) but not in \( \sigma \). More precisely if we consider \( A_\sigma(p, q) \) as a member of the family of functions

\[ A_\sigma^{ij} = \mathcal{F}(\Omega, R^i_n R^j_n \Omega) \]

where \( i \) and \( j \) run independently over all the generalized retarded \( n \) point products, it turns out, on the basis of the spectral condition and the edge
of the wedge theorem, that the functions $A^i_j(p, q)$ are for fixed $\sigma$ (this term will have to be specified later) different boundary values of one and the same function [which, for simplicity we will again denote by $A_\sigma(p, q)$] analytic in a domain $\{(p, q) \in \Omega_\sigma \times \Omega_\sigma\}$. Here $\Omega_\sigma$ is the envelope of holomorphy of the $n$ point function in which the region of coincidence $\mathbf{R}^C = \{p : \sum_{i=1}^n p_i^2 < M^2_n \text{ for all } I \in (1, 2, \ldots, n)\}$ has been replaced by the "shifted" region $\mathbf{R}^{C'} = \{p : \sum_{i \in I} (p_i + a)^2 < M^2_n \text{ for all } I \in (1, 2, \ldots, n)\}$. Note that $\Omega_\sigma \times \Omega_\sigma$ is a topological product of twice the same region. The reader will immediately notice that for $n = 2$, $(A_\sigma(p, q)$ reduces to the well-known absorptive part of the four-point function studied first by Bogoliubov and co-workers in connection with the proof of dispersion relations and then by Lehmann, who found also its envelope of holomorphy $\Omega_\sigma$. The above statements are simple generalizations.

On the other hand, the algebra of the generalized retarded functions tells us that the commutator $(\Omega, [R^i_n, R^j_n]_\Omega)$ can be expressed as the difference of (in general different) pairs of fully retarded functions:

$$(\Omega, [R^i_n, R^j_n]_\Omega) = r_{2n}^\alpha - r_{2n}^\beta .$$

Translated into momentum space this tells us, in view of (2.8), that the "absorptive part" $A_\sigma$ is the difference of two different boundary values of the full $2n$ point function $\tilde{r}_{2n}(k)$. This fact adds, in principle, new information for the function $A$; it can in particular result in an enlargement of the domain $\Omega_\sigma \times \Omega_\sigma$ described above. Indeed, that is what happens in the case of the four-point function as shown by Martin.

As a matter of fact, a rigorous proof of these statements requires some gymnastics with distribution theory and analytic completion.
The above remarks about the analyticity properties of $A$ being needed in the next Section, let us turn back to the inequality (2.7). If we choose the test function there to be of the form $\varphi(\sigma, p) = \chi(\sigma) f(p)$, with $\chi \in S(\mathbb{R}^4)$ and $f \in S(\mathbb{R}^4)$, that condition takes the form:

$$\int d\sigma |\chi(\sigma)|^2 \left( \int A_\sigma(p, q) \overline{f(p)} f(q) \, dp \, dq \right) \geq 0 \quad (2.10)$$

By a well-known theorem of Schwartz, the positivity of (2.10) implies that $A_\sigma$ is a positive measure with respect to $\sigma$. The term "$\sigma$ fixed" will therefore have to be understood in the sense of a convolution with a positive test function $|\chi(\sigma)|^2$ having its support centered sufficiently closely to the desired value. It can actually be shown that the regularization with respect to only a timelike direction will suffice. Also the symbol $\Omega_\sigma$ will have to be understood as

$$" \Omega_\sigma " = \bigcap_{\sigma \in \Omega} \Omega_\sigma , \quad \Omega_\sigma = \text{supp} |\chi|^2$$

In what follows we will simply suppress the integration over $\sigma$ in (2.10).

3. EXTENSION OF THE POSITIVITY CONDITION INTO THE COMPLEX DOMAIN.

The aim of this Section is to "extend" the condition

$$\int A(p, q) \overline{f(p)} f(q) \, dp \, dq \geq 0 \quad (3.1)$$

for all $f \in \mathcal{S}(\mathbb{R}_N^N)$, $N = 4(n - 1)$

into the whole domain of analyticity of the function $A(p, q)$ ($\sigma$ being fixed once and for all we shall drop it in the notation). As it was discussed in the preceding paragraph, $A$ is certainly analytic in a domain of the type $\Omega \times \Omega$. We shall need also the following two simple properties of the domain.
Ω : (a) Ω is invariant under complex conjugation Ω = Ω*, and (b) Ω contains real points of analyticity. Here Ω* denote the set Ω* = {p : p ∈ Ω} where the bar indicates complex conjugation: if p = Re p + i Im p, then |p| = Re p - i Im p.

The property (a) is certainly true for the primitive domain of the n-point function and therefore also for its envelope of holomorphy Ω. The property (b) follows from the fact that the region of coincidence S(σ) is non-empty: by the edge of the wedge theorem all its points are (real) points of analyticity.

We are now ready to formulate the

THEOREM 1.

If the function A(p, q) is analytic in a schlicht domain Ω × Ω ⊆ C_N × C_N such that Ω contains a real open set R ∈ C_N and if on R × R ⊆ R_N × R_N, A(p, q) satisfies the positivity condition (3.1) for every test function f ∈ A(R), then it satisfies also the three following conditions:

A) \[ \int_{\Omega \times \Omega} A(p, q) g(p) g(q) \, d\mu_p \, d\mu_q \geq 0 \]

for all g ∈ L^2(ω) and all ω ⊆ Ω, ω being any open set in C_N with compact closure such that closure ω ⊆ Ω, and d \( \lambda_p \),

---

*) Our notation is somewhat inconsistent since the same letters p and q stand for real variables as in (3.1), where A(p, q) represents the boundary value of an analytic function, and for complex variables varying in Ω × Ω, where they serve as arguments of the (unique!) analytic extension of the boundary value in question. This analytic extension is again denoted by A(p, q). It is hoped that this notational simplification will not lead to confusion; from the context it should be clear whether the variables in question are to be considered as real or complex.
resp. $d\lambda_p = (2i)^{-N} dp \wedge dp$, resp. $d\lambda_q = (2i)^{-N} dq \wedge dq$ [i.e., $A$]

B) - There exists a sequence of functions $f_v(p) \in \mathcal{A}(\Omega)$, $v = 1, 2, 3, \ldots$, $\mathcal{A}(\Omega)$ denoting the set of functions analytic in $\Omega$, such that

$$A(p, \overline{q}) = \sum_{v=1}^{\infty} f_v(p) \overline{f_v(q)}$$

the series being uniformly convergent in $\Omega \times \Omega$ **).

C) - The quadratic form

$$\alpha_p(a, a) = \sum_{\alpha, \beta} \frac{a_\alpha}{\alpha!} \frac{\overline{a}_\beta}{\beta!} \alpha^\beta A(p, \overline{p})$$

defined on all finite sequences of complex numbers $\{a_\alpha\}$ is positive definite for all $p \in \Omega$.

All these three conditions are equivalent.

The formula C) needs some explanations. In it the notation of Schwartz \(^{22}\) for multi-indices was used: $\alpha = \{\alpha_1, \alpha_2, \ldots, \alpha_N\} \subset \mathbb{Z}_N^+$ denotes a sequence of $N$ non-negative integers.

*) Note that $A(p, q)$ being analytic in $\Omega \times \Omega^*$, $A(p, q)$ is analytic in $p \in \Omega$ and anti-analytic in $q \in \Omega$.

**) A series of functions is said to be uniformly convergent in an open set $U$ if it converges uniformly in every compact subset of $U$. 
\[ \alpha! = \alpha_1! \cdots \alpha_N! \quad \text{,} \quad \beta! = \beta_1! \cdots \beta_N! \]

\[ \frac{\partial^\alpha}{\partial \beta_1} \cdots \frac{\partial^\alpha}{\partial \beta_N} = \left( \frac{\partial}{\partial \beta_1} \right)^{\alpha_1} \cdots \left( \frac{\partial}{\partial \beta_N} \right)^{\alpha_N}, \quad \frac{\partial^\beta}{\partial \beta_1} \cdots \frac{\partial^\beta}{\partial \beta_N} = \left( \frac{\partial}{\partial \beta_1} \right)^{\beta_1} \cdots \left( \frac{\partial}{\partial \beta_N} \right)^{\beta_N}. \]

For later use, we note also

\[ |\alpha| = \alpha_1 + \cdots + \alpha_N, \quad p^\alpha = p_1^\alpha \cdots p_N^\alpha. \]

In C), the summation extends formally over all \( \mathbb{Z}_N^- \times \mathbb{Z}_N^+ \) but only a finite number of the \( a_\alpha \) is supposed to be \( \neq 0 : a_\alpha = 0 \) for all \( |\alpha| > n \) for some \( n \). The factorials \( \alpha! \beta! \) were introduced for later convenience. We want to show that the condition C) involves only values of the function \( A(p, q) \) on the "diagonal plane" \( q = \bar{p}, \) which is a linear subspace of \( \mathbb{C}_{2N} = \mathbb{C}_N \times \mathbb{C}_N \) of real dimension \( 2N \). Let us denote it by \( \mathcal{D}_{2N} \). \( \mathcal{D}_{2N} \) can be parametrized either by the real and imaginary on the vector \( p = x + iy, \)

\[ x = \frac{(p + \bar{p})}{2}, \quad y = \frac{(p - \bar{p})}{2i}, \]

or formally by \( p \) and \( \bar{p} \). Given an arbitrary \( C^\infty \) function \( f \) on an open set \( \omega \subset \mathcal{D}_{2N} \), its value in a point \( p \) can be denoted by \( f(x, y) \) or formally by \( f(p, \bar{p}) \); its derivatives \( \frac{\partial^\alpha}{\partial p^\beta} f \) are by definition to be computed by using the formulae:

\[ \frac{\partial}{\partial \beta} \frac{\partial}{\partial \beta} = \frac{1}{2} \left( \frac{\partial}{\partial x} - i \frac{\partial}{\partial y} \right), \quad \frac{\partial}{\partial \beta} \frac{\partial}{\partial \beta} = \frac{1}{2} \left( \frac{\partial}{\partial x} + i \frac{\partial}{\partial y} \right). \]

The function \( f \) will be said to be \textit{real} analytic in \( \omega \) if for every \( p_o \in \omega \) it can be represented by its Taylor series

\[ f(p, \bar{p}) = \sum_{\alpha, \beta} \frac{(p - p_o)^\alpha (\bar{p} - \bar{p}_o)^\beta}{\alpha! \beta!} \frac{\partial^\alpha}{\partial p^\beta} f(p, \bar{p}_o) \tag{3.2} \]

absolutely converging in a sufficiently small polydisc

\[ P = \{ p : |(p - p_o)_i| < R_i, \quad i = 1, \cdots, N \}. \]
If we replace \( \bar{p} \) by \( q \) in the series (3.2), the series will continue to converge absolutely for \( (p, q) \in P \times P^* \) defining there an analytic function \( f(p, q) \) - the unique analytic continuation of \( f(p, \bar{p}) \). In this case the formal notation acquires a real meaning and proves our assertion.

Before proceeding to the proof we wish to make still a few remarks. It is evident that the representation B) displays positivity in the most explicit way. From it, A) and B) follow immediately. For example, in order to get C), we have only to apply the differential operator \( P(\partial_p)P(\partial_q) \) to the series C) and put \( q = p \), where \( P \) is given by

\[
P(\partial_p) = \sum_{\alpha} \frac{\partial^\alpha}{\alpha!} \partial_p^\alpha.
\]

The function \( A(p, \bar{q}) \) resembles very much to a Bergman kernel associated with a suitably defined Hilbert space of functions analytic in a domain \( \Omega \). The Bergman theory proceeds, roughly speaking, in the direction \( A) \Rightarrow B) \Rightarrow C) \), while our proof of Theorem 1 will follow the direction \( (3.1) \Rightarrow C) \Rightarrow A) \Rightarrow B) \).

**Proof of C).**

In order to show C), let us insert for \( f \) in formula (3.1) the expression

\[
f(p) = \sum_{|\alpha| \leq n} \frac{\partial^\alpha}{\alpha!} (-)^{|\alpha|} \partial_p^\alpha \sigma_N(p - p'), \quad p' \in R \tag{3.3}
\]

or, to be more precise, let us take a sequence of functions \( \xi_n \in \mathcal{D}(R) \) converging to the distribution (3.3) in the topology of \( \mathcal{D}'(R) \). Since \( A(p, q) \) is \( C^\infty \) in \( R \times R \), the result will be the same. Here \( \delta_N \) is the \( N \) dimensional Dirac function. As \( p' \) is any fixed point in \( R \) we obtain

\[*\) Most of the author's knowledge about the Bergman-Bochner theory derives from a book by Meschkowski 23), especially from Chapters IV and XII.\]
for all $p \in \mathbb{R}$.

In this inequality all the $a_{\alpha}^p = 0$ for $|\alpha| > n$, some $n$, but we are allowed to drop this condition provided the resulting series converges absolutely. That is what we will do presently. Let $p \in \mathbb{R}$, and let $D$ be a polydisc $D = \{ z \in \mathbb{C}^n : |z_i| < R_i, \ i = 1, \ldots, N \}$ such that $\{p\} + D \subset \Omega$ and let $z \in D$. Then by introducing

$$a_{\alpha}^p = \sum_{|\gamma| \leq n} \frac{b_\gamma}{\gamma!} (\alpha - \gamma)^{\alpha - \gamma}$$

for all $\alpha \in \mathbb{Z}^n_+$, $\gamma \in \mathbb{Z}^n_+$ into the series (3.4) we get the inequality $Q_{p+z}(b, b) \geq 0$ if we note that the Taylor series of the function $A(p + z, p + z)$ as well as all its derivatives converge. Since any point $p \in \Omega$ can be connected to a given point $p_0 \in \mathbb{R}$ by a finite chain of polydiscs, a finite number of repetitions of the above substitution will yield us the inequality $Q_p(a, a) \geq 0$, which proves $C$.

Partial proof of $B$).

We will prove $C) \Rightarrow B)$ for $\Omega$ a polydisc $P$. Let $P = \{ p_0 \} + D$, $p_0 \in \mathbb{R}$, $D$ a polydisc with its centre at the origin such that $p_0 \subset \Omega$.

Let us introduce, following Bergman and Bochner \cite{7,8,23}, the Hilbert space $\mathcal{H}_P = \mathcal{O}(P) \cap L_2(P)$ of functions analytic and square integrable in $P$ with the scalar product

$$\langle f, g \rangle = \int_P \overline{f(p)} \ g(p) \ d\lambda_p$$

and norm $\|f\|^2 = (f, f)$.

The fundamental property of this space of functions is the fact that the value of the function $f$ at a point $p \in P$ is a continuous functional of $f$ considered as an element of $\mathcal{H}_P$:

$$|f(p)| \leq N_p \|d\| \quad \text{with} \quad N_p = C \ d(p)^{-N/2}$$
where $d(p)$ is the distance of the point $p$ to the boundary of $P$, $C$ a numerical constant. From this, it follows immediately that the strong convergence $f_n \to f$ in $H_p$ implies the pointwise convergence $f_n(p) \to f(p)$ uniformly in every compact subset of $P$. Equation (3.6) is an easy consequence of the Cauchy integral representation for analytic functions (Ref. 23, Chapter IV). It is also immediate to verify that the powers

$$\varphi_{\alpha} = (p - p_0)^\alpha N^{-1}_{\alpha} = z^\alpha N^{-1}_{\alpha}, \quad \alpha \in \mathbb{Z}_N^+$$

where

$$N_{\alpha}^2 = \int_D |z^\alpha|^2 \, d\lambda(z)$$

are normalization constants, form a complete orthonormal set in $H_p$.

Let us associate to the function $A(p, q)$ the bounded linear operator $A \in \mathcal{L}(H_p)$ by the formula

$$(Af)(p) = \int_P A(p, q) f(q) \, d\lambda_2.$$

$A$ is evidently bounded since $A(p, q)$ is an analytic and hence bounded function in the closure of $P \times P$. It is also Hermitian and positive. This can be seen by introducing into the formula

$$(f, Af) = \int_{P \times P} \bar{f}(p) \, \hat{A}(p, q) f(q) \, d\lambda_p \, d\lambda_q$$

for $f$ the polynomial $f = \sum a_{\alpha}(p - p_0)^\alpha N^{-1}_{\alpha}$ and for $A(p, q)$ its Taylor series centered at $p_0$. One gets $(f, Af) = Q_{p_0}(a, a)$, where $Q$ is the quadratic form (3.4), which was shown to be positive. Since polynomials are dense in $H_p$, it follows that $(f, Af) \geq 0$ for all $f \in H_p$. This is the inequality $\Lambda$) for $w = P$ and $f \in \mathcal{O}(p) \cap L_2(P)$. Finally, $A$ has a finite trace. Indeed, by computing the trace with the help of the orthonormal system $\{\varphi_{\alpha}\}$ using again the Taylor expansion for $A(p, q)$, one obtains

$$\text{tr} \, A = \int_P A(p, \bar{p}) \, d\lambda_p < \infty$$
All these properties imply that $A$ is of the Hilbert-Schmidt type and has therefore a purely point spectrum. The set of all the eigenfunctions of $A$

$$\int_{\mathcal{P}} A(p, q) g_v(q) d\lambda_v = \lambda_v g_v(p), \quad v = 1, 2, 3, \ldots \quad (3.8)$$

is a complete set of orthonormal functions in $\mathcal{H}_\mathcal{P}$. $(f, Af) \geq 0$ entails $\lambda_v \geq 0$. Since for fixed $q$ $A(p, q) = f(p)$ is an element of $\mathcal{H}_\mathcal{P}$, we may expand $f$ into a Fourier series with respect to the orthonormal set \{g_v\} : $f = \frac{1}{\sqrt{|q|}} \sum_{v=1}^{\infty} a_v g_v$, with $a_v = (g_v, f) = \lambda_v g_v(q)$ because of (3.8).

Now, according to (3.6), strong convergence entails uniform pointwise convergence, and therefore the series

$$A(p, q) = \sum_{v=1}^{\infty} \lambda_v g_v(p) g_v(q) = \sum_{v=1}^{\infty} f_v(p) f_v(q)$$

with $f_v = \lambda_v^{1/2} g_v \quad (3.9)$

converges uniformly in $p \in \mathcal{P}$ for each fixed $q \in \mathcal{P}$. It remains only to be shown that the series (3.9) converges uniformly in $\mathcal{P} \times \mathcal{P}$. It is useful for later purposes to proceed as follows. By putting $q = p$ in (3.9) we get

$$A(p, p) = \sum_{v=1}^{\infty} |f_v(p)|^2 \quad (3.10)$$

and, since this is a series of positive continuous functions in $\mathcal{P}$ converging to a continuous function in $\mathcal{P}$, Dini's theorem tells us that the series converges uniformly in $\mathcal{P}$. The Cauchy inequality yields:

$$|A(p, q)|^2 \leq \sum_{v} |f_v(p) f_v(q)|^2 = \sum_{v} |f_v(p)|^2 \sum_{\mu} |f_\mu(q)|^2 = A(p, p) A(q, q) \quad (3.11)$$
This shows that the series (3.9) automatically converges absolutely and, as a little reflection shows, also uniformly in \( P \times P \) since the two series on the right-hand side of the inequality do so.

The uniform convergence of (3.9) evidently implies the inequality \( A \) for any \( w \in P \) and any \( f \in L_2(w) \). Thus, Theorem 1 is proved in the special case \( \Omega = P \).

The proof of Theorem 1 will be complete if we prove the following theorem, which has an independent interest (compare Ref. 23, Chapter XII).

**Theorem 2.**

If \( A(p, \bar{p}) \) is real analytic in \( \Omega \) and if some polydisc \( P_0 \) (centered at \( p_0 \in \Omega \)) the representation (3.10) is valid with the \( f_v \) analytic in \( P \), then all the functions \( f_v \) can be continued analytically into all of \( \Omega \) and the representation (3.10) remains valid in \( \Omega \) in the sense of uniform convergence. The function \( A(p, q) \) defined by the series

\[
A(p, q) = \sum_v f_v(p) \overline{f_v(q)}
\]

(3.12)

converges uniformly and absolutely in \( \Omega \times \Omega^* \) continues analytically the function \( A(p, p) = A(p, q)|_{q=p} \) into \( \Omega \times \Omega^* \).

**Proof.**

As already explained, \( A(p, \bar{p}) \) real analytic in \( \Omega \) means that for any \( p_i \in \Omega \) there is a (non-empty) polydisc \( P_i \) centered at \( p_i \) in which the Taylor series of \( A(p, \bar{p}) \)

\[
A(p, \bar{p}) = \sum_{\alpha, \beta} A_{\alpha \beta}^i (p - p_i)^\alpha (\bar{p} - \bar{p}_i)^\beta
\]

(3.13)

converges absolutely. Since by the Heine-Borel lemma any point \( p \in \Omega \) can be connected to \( p_0 \in P_0 \) by a finite chain of polydiscs \( P_r \) such that \( p_r \in P_{r-1} \) (\( r = 1, \ldots, m \)) and \( p \in P_m \), it is sufficient to show that (3.10) can be "continued" from \( P_0 \) to \( P_1 \). Let \( R = (R_1, \ldots, R_N) \) be the radius of \( P_1 = \{ p : |p - p_i| < R_i, i = 1, \ldots, N \} \). Let
the Taylor series of \( \hat{f}_\nu \); they converge all a polydisc \( P* \subset P^0 \cap P^1 \) centered at \( p_1 \). We have on the one hand, the Cauchy inequalities

\[
|A_{\alpha\beta}^1| < \frac{M}{R^{2\alpha+\beta}} \quad \text{for some } M
\]

since (3.13) for \( i = 1 \) converges in \( P^1 \), and on the other the representation

\[
A_{\alpha\beta} = \sum_{\nu=1}^{\infty} f_{\alpha\nu} \overline{f}_\nu \beta , \quad (3.16)
\]

which we get by inserting the series (3.14) into (3.10) by inverting summation signs. This we are allowed to do since Theorem 2 is valid in \( P^0 \) by the remarks following formula (3.9). Putting \( \alpha = \beta \), (3.15) and (3.16) yield the inequality

\[
A_{\alpha\alpha}^1 = \sum_{\nu} |f_{\alpha\nu}|^2 < \frac{M}{R^{2\alpha}} \quad (3.17)
\]

and a fortiori \( |f_{\alpha\nu}| < \frac{1}{M^2/R^{2\alpha}} \). This shows that the Taylor series (3.14) keeps on converging absolutely in all of \( P^1 \). We have to show that the series (3.10) behaves likewise. For that purpose let us apply to the series

\[
\sum_{\alpha} f_{\alpha\nu} Z^\alpha = \sum_{\alpha} \{f_{\alpha\nu} R^\alpha (Z/R)^{\alpha/2} (Z/R)^{\alpha/2} \} , \quad Z = p - p_1
\]

the Schwartz inequality. We get

\[
|f_{\nu}(p)|^2 \leq \sum_{\alpha} |f_{\alpha\nu}|^2 R^{2\alpha} |Z|^{\alpha} \cdot \sum_{\beta} |Z|^{\beta} .
\]

Combining this with the inequality (3.17), we obtain

\[
\sum_{\nu} |f_{\nu}(p)|^2 \leq M (\sum_{\alpha} |Z|^{\alpha}) = M \prod_{i=1}^{N} (1 - \frac{|p_i - p_{1i}|}{R_i})^{-2} < \infty
\]

for all \( p \in P^1 \).
This proves the (3.10) part of the theorem. But the remaining part follows immediately from what has been said in the proof of formula (3.9).

The Theorem 2 shows that the "sensitive" points of the analytic function \( A_0(p, q) \) lie in the immediate neighbourhood of the "diagonal plane" \( \mathcal{D}_{2N} = \{ (p, q) : p = q \} \). If by using any other information we succeed to enlarge the domain of analyticity of \( A \) in a neighbourhood, however "thin" of the diagonal plane, this enlargement becomes automatically a topological product. The following Theorem 3 will strengthen this conclusion since in it not even continuity of the function \( A(p, \bar{p}) \) will be required. This theorem is inspired by the Bernstein theorem of classical analyses on the convergence of the Taylor series of a function having all its derivatives positive \(^*\). But in spite of its apparent generality, the author believes that Theorem 2 could be more useful for practical applications.

**Theorem 3.**

Let \( A(p, \bar{p}) \in \mathcal{A}^1(\Omega) \) satisfy - in the sense of distributions - the positivity condition (C):

\[
\sum_{\alpha, \beta} \frac{\partial^{\alpha} \bar{\alpha}}{\alpha! \beta!} \frac{\partial^\beta}{\partial \bar{p}^\beta} A(p, \bar{p}) = Q(p, \alpha, \alpha) \geq 0 \tag{3.18}
\]

everywhere in \( \Omega \) for all finite sequences \( \alpha \). Then \( A(p, \bar{p}) \) is the restriction to the "diagonal plane" \( p = \bar{q} \) of a function \( A(p, q) \) analytic in \( \Omega \times \Omega^* \).

**Proof.**

It is enough to show that \( A(p, \bar{p}) \) is real analytic in \( \Omega \), for then the methods of proof of Theorems 1 and 2 will evidently lead to the statement of Theorem 3.

---

*) The author would like to thank D. Bessis for drawing his attention to the Bernstein theorem during the elaboration of this work. His thanks are also due to Dr. H. Epstein, who suggested the distribution part of Theorem 3.
By noting that
\[ \Delta_i = 4 \frac{\partial^2}{\partial p_i \partial p_i} \]
are two-dimensional Laplace operators, we get, as a consequence of (3.18), the inequalities:
\[ \Delta_1^n \Delta_2^n \cdots \Delta_N^n \geq 0 \quad \text{for all} \quad (n_1, \ldots, n_N) \in \mathbb{Z}_N^+ \]
(\(\Delta_0 = 1\)) \hspace{1cm} (3.19)
and also
\[ \mu_n = \Delta^n A \geq 0 \quad \text{for} \quad n = 0, 1, 2, \ldots \] \hspace{1cm} (3.20)
where \(\Delta = \Delta_1 + \Delta_2 + \cdots + \Delta_N\) is the Laplace operator with respect to all the variables.

Equation (3.20) implies \(A \in C^\infty(\Omega)\). To see this, we shall use a classical argument \((22), (24)\). We first notice that the \(\mu_n\) being positive distributions are measures. The second remark is that the elementary solution \(G_n(r)\) of the equation \(\Delta_n^F = \delta_{2N}\) is in \(C^{2n-2N-1}(\mathbb{R}_{2N})\) provided \(n > N\) \((22), (24)\). Here \(r^2 = |p_1|^2 + \cdots + |p_N|^2\). Therefore \(G_n * (\phi \mu_n)\) is also in \(C^{2n-2N-1}(\mathbb{R}_{2N})\) for any \(\phi \in \mathcal{D}(\Omega)\). By choosing \(\phi(p) = 1\) in a sphere \(S \subset \Omega\), we find that the measure \(F_n = A - G_n * (\phi \mu_n)\) satisfies the equation \(\Delta_n^F = 0\) in \(S\). But any solution of the last equation is \(C^\infty(S)\) and therefore \(A \in C^\infty(S)\). \(n\) being arbitrary and \(S \subset \Omega\) also arbitrary we conclude that \(A \in C^\infty(\Omega)\).

Knowing this, we want to show that the Taylor series of \(A\) at any given point \(p_o \in \Omega\) converges absolutely in every polydisc contained in \(\Omega\). Without loss of generality we shall take \(p_o\) to be the origin and it will be sufficient to show that the coefficients of the formal power series
\[ S(p) = \sum_{\alpha, \beta} \frac{\alpha! \beta!}{\alpha! \beta!} \frac{\partial^\alpha}{\partial p^\alpha} \frac{\partial^\beta}{\partial \bar{p}^\beta} A(0, 0) = \sum_{\alpha, \beta} A_{\alpha \beta} p^\alpha \bar{p}^\beta \]
satisfy the Cauchy inequalities

$$|A_{\alpha \beta}| < N^{\alpha + \beta}$$  \hfill (3.21)

where $R = (R_1, \ldots, R_N)$ is the radius of any polydiscs contained in $\Omega$.

Let us put $p_j = r_j e^{i \varphi_j}$ ($r_j \geq 0$, $\varphi_j$ real) and let us study the mean value of the function $A$ over the angles:

$$M_\alpha(r_1, \ldots, r_N) = (2\pi)^{-N} \int_0^{2\pi} \cdots \int_0^{2\pi} A(r_1 e^{i \varphi_1}, \ldots, r_N e^{i \varphi_N}) \, d\varphi_1 \cdots d\varphi_N.$$

We shall consider only the case $N = 1$ in detail. With the help of the Green's formula, we get:

$$\frac{d M_\alpha}{dr} = (2\pi)^{-1} \int_0^{2\pi} \frac{\partial}{\partial r} A(r e^{i \varphi}) \, dr = r^{-1} \int_0^{2\pi} r' (2\pi)^{-1} \cdot \int_0^{r'} \Delta A(r', e^{i \varphi}) \, d\varphi = r^{-1} \int_0^{r'} dr' \Delta M_\alpha(r') \ .$$

or by integrating:

$$M_\alpha(r) = M_\alpha(0) + \int_0^{r} dr' \int_0^{r'} dr'' \frac{r''}{r'} M_{\alpha+1}(r''), \quad (3.22)$$

Here we have introduced the notation:

$$M_{\alpha}(r) = (2\pi)^{-1} \int_0^{2\pi} \Delta^\alpha A(r e^{i \varphi}) \, d\varphi, \quad \alpha = 0, 1, 2, \ldots, \quad M_0 = M.$$

Equation (3.22) can be also written in the form

$$M_{\alpha}(r) = M_{\alpha}(0) + \int_0^{r} G(r', r') M_{\alpha+1}(r') \, dr' \ ,$$

with

$$G(r', r') = r' \Delta n \frac{r}{r'} \geq 0 \ .$$

By $n$ fold iteration we obtain:

$$M_\alpha(r) = \sum_{\alpha=0}^n M_{\alpha}(0) \int_0^{r} G_{\alpha}(r', r') \, dr' + \int_0^{r} G_{n}(r', r') M_n(r') \, dr' \quad (3.23)$$

where $G_{\alpha}$ is the $\alpha$ times iterated kernel. One finds easily:
\[
\int_0^r G_\alpha (r, r')dr' = \left(\frac{r}{4}\right)^{2\alpha}/(\alpha !)^2
\]
and
\[
N_\alpha (0) = A_\alpha A(0) = 4^\alpha \partial_\alpha \partial_\beta A(0, 0).
\]
Now, since \( G_n \) is positive and by (3.19) all the \( N_\alpha (r) \) are also positive, we obtain by dropping the last term in (3.23), the inequality

\[
N_\alpha (r) > \sum_{|\alpha| \leq n} A_{\alpha \beta} r^{2\alpha}
\]
for all \( 0 \leq r \leq R \) and all \( n \), which, in turn, implies the Cauchy inequality

\[
A_{\alpha \beta} \leq M/r^{2\alpha}, \quad M = N_\alpha (R).
\]

It is almost evident that this last formula is also valid in the case \( N > 1 \) if we replace in it the index \( \alpha \) by the corresponding multi-index \( \alpha = (\alpha_1, \ldots, \alpha_N) \) and \( R \) by \( R = (R_1, \ldots, R_N) \); to see this, one has only to apply formula (3.23) to each of the variables \( r_1, \ldots, r_N \) separately.

In order to get the full Cauchy inequality (3.21), we notice that the positivity condition (3.18) implies \( A_{\alpha \beta} = \overline{A_{\beta \alpha}} \) and \( |A_{\alpha \beta}|^2 \leq A_{\alpha \alpha} A_{\beta \beta} \).

Thus the convergence of the formal power series at each \( p \in \Omega \) is established. It remains only to be shown that these series converge to the function \( R(p, \bar{p}) \). But this is an immediate consequence of the classical Taylor formula with the rest term. Therefore, Theorem 3 is proved *).

*) After the completion of this work, Professor P. Lelong has kindly informed me at the last Strasbourg meeting that in 1948, by using somewhat different methods, he had proved the following theorem: if a \( C^\infty \) function satisfies the conditions (3.20) in a domain, then the function is real analytic there 25).
The rest of this Section will be taken up with the generalization to the case when functions with a different number of fields are involved in the positivity condition. Our remarks will be only sketchy, since, except for one point, essentially only notational questions will be at stake.

Let us denote the Fourier transform of \((\Omega, R_n^* R_m \Omega)\) by

\[
\mathcal{A}_{nm}(\sigma; p_n, q_m) = \mathcal{F}(\Omega, R_n^* R_m \Omega)
\]

\[(n = 1, 2, \ldots; m = 1, 2, \ldots)\]

Here again \(p_n \in \mathbb{R}^4(n-1)\) are the internal momentum variables of the "cluster" \(R_n^*\) and \(q_m \in \mathbb{R}^4(m-1)\) those of the cluster \(R_m\). \(\sigma\) is the total energy and momentum created by any of the clusters from the vacuum state. We will keep it again fixed and hence drop it from our notation.

The discussion at the end of Section 2 shows that \(\mathcal{A}_{nm}\) is a boundary value of a function analytic at least in the domain \(\Omega_n(\sigma) \times \Omega_m(\sigma)\), where \(\Omega_i(\sigma)\) is the "\(\sigma\)-shifted" domain of analyticity of the \(i\) point function. Each of these domains contains real points and is invariant under complex conjugation. The original positivity condition reads

\[
\sum_{1 \leq n, m \leq N} \int A_{nm}(p_n, q_m) \overline{F_n(p_n)} F_m(q_m) \, dp_n \, dq_m \geq 0
\]

\[(3.25)\]

for all \(f_n \in \mathcal{S}(\mathbb{R}^4(n-1))\), \(n = 1, \ldots, N\) [note that \(\mathcal{S}(\mathbb{R}^4) = \mathcal{S}\), \(\mathcal{S}_1 = \mathbb{C}\), the set of complex numbers].

In order to formulate the generalization of the condition A), of Theorem 1, let us introduce the (pre-) Hilbert space \(\mathcal{H}_\omega\), whose elements are \(N\)-tuples of analytic functions:

\[
f = \{f_1(p_1), f_2(p_2), \ldots, f_N(p_N)\} \text{ with } f_n \in \mathcal{H}(\omega_n) \cap L^2(\omega_n),
\]

\[
\omega_n \supseteq \Omega_n
\]
and with the scalar product defined by:

$$
(f, g) = \sum_{n=1}^{N} \int_{\Omega_n} f_n(p_n) \overline{g_n(p_n)} \, d\lambda_{pn}
$$

(3.26)

where \( d\lambda_{pn} \) is the Lebesgue measure in \( \mathbb{S}_{4(n-1)} \). \( H_{\omega} \) is simply a finite direct sum of Bergman-Hilbert spaces and therefore itself a Hilbert space. \( H_{\omega} \) inherits the, for us, essential property of a Bergman-Hilbert space: the value \( f_n(p_n) \) at the point \( (n, p_n) \) of an \( f \in H_{\omega} \) is a continuous linear functional of \( f \):

$$
|f_n(p_n)| \leq M_n(p_n) \left( \int_{\Omega_n} |f_n(p_n)|^2 \, d\lambda_{pn} \right)^{1/2} \leq M_n(p_n) \|f\| \quad (3.27a)
$$

with \( M_n(p_n) = C_n d(p_n)^{-4(n-1)/2} \), \( C_n \) a numerical constant [compare formula (3.6)].

To the \( N \times N \) matrix of functions \( (A_{nm}) \), we associate now the linear operator \( A \) on \( H_{\omega} \) defined by

$$
(Af)_n(p_n) = \sum_{m=1}^{N} \int_{\Omega_n} A_{nm}(p_n, q_m) \overline{f_m(q_m)} \, d\lambda_{qm}
$$

which is obviously bounded since \( \omega_n \subseteq \Omega_n \).

What one wants to prove is that (3.25) implies the generalized condition

$$
\Lambda' \quad (f, Af) \geq 0 \quad \text{for all} \quad f \in H_{\omega}.
$$

As it was seen in the proof of Theorems 1 and 2, it is actually sufficient to prove this inequality for \( \omega_n = P_n \) = any polydisc \( \subseteq \Omega_n \) centered at some real point of analyticity \( p_n' \in P_n \) \( (n = 1, \ldots, N) \). But that can be easily done by inserting for the test functions in (3.25) linear combinations of \( \delta \) functions as in formula (3.3) and then choosing, as in proof of Theorem 1, powers as a complete orthonormal system of functions in \( H_p \).
Since
\[
\text{tr } A = \sum_{n=1}^{N} \int \Lambda_{nn}(p_n, p_n) \, d\lambda_n \tag{3.27b}
\]
is also obviously finite, the diagonalization of \( A \) yields a complete orthonormal system of functions \( \{ \varphi_v \} : A \varphi_v = \lambda_v \varphi_v \), \( \lambda_v \geq 0 \), \( v = 1, 2, 3, \ldots \).

By introducing the functions \( \xi^v = \lambda_v^{1/2} \varphi_v = (f_{1v}(p_1), \ldots, f_{Nv}(p_N)) \) the fundamental inequality (3.27a) again leads to the uniformly converging representation:
\[
A_{nm}(p_n, \overline{p}_m) = \sum_{v=1}^{\infty} f_{nv}(p_n) \overline{f}_{mv}(q_m),
\]
\( (n, m = 1, \ldots, N) \) (3.28)

Here the functions \( f_{nv}(p_n) \) are analytic in \( P_n(n = 1, \ldots, N) \).

By considering the diagonal term \( n = m \) it follows from Theorem 2 that the functions \( f_{nv} \) can be analytically continued to the whole of \( \Omega_n(n = 1, \ldots, N) \), and the Schwartz inequality
\[
|A_{nm}(p_n, \overline{p}_m)|^2 \leq \sum_{v} |f_{nv}(p_n) \overline{f}_{mv}(q_m)|^2 \leq \sum_{v} |f_{nv}(p_n)|^2 \sum_{v} |f_{mv}(q)|^2
\]
\[
= A_{nn}(p_n, \overline{p}_n) A_{mm}(q_m, \overline{q}_m) \tag{3.29}
\]
tells us, again through Theorem 2, that the series automatically converges uniformly in the whole of \( \Omega_n \times \Omega_m \).

Therefore we have proved the following theorem:

**Theorem 4.**

Let a set of \( N \times N \) continuous functions \( A_{nm}(p_n, q_m) \) be defined in \( R_n \times R_m \), where \( R_n \) is a (real) neighbourhood of a point \( p_n = p_n' \) in \( R_4(n-1) \); let this set of functions satisfy condition (3.25) for all \( f_n \in \mathcal{K}(R_n) \) \( (n = 1, \ldots, N) \); let all the functions \( A_{nm} \) be analytic in a complex neighbourhood of the points \( p_n = p_n' \), \( q_m = q_m' \); let further
the "diagonal" functions $A_{nn}(p_n, p_n)$ be real-analytic in domains $\Omega_n \in \mathcal{C}_A(n-1)$ containing the real point $p_n = p'_n (n = 1, \ldots, N)$. Then the functions $A_{mn}(p_n, q_m)$ can be analytically continued into $\Omega_n \times \Omega^*_m (n, m = 1, \ldots, N)$. Furthermore the matrix of functions $A = (A_{nm})$ can be "diagonalized" there, that is, there exists a sequence of functions $f_{mn} \in \mathcal{H}(\Omega_n) (\nu = 1, 2, 3, \ldots), (n = 1, \ldots, N)$ such that the representation (3.28) is valid in $\Omega_n \times \Omega^*_m$ in the sense of the uniform convergence of the series.

**Generalizations and outlook.**

The main tool for getting Theorems 1 to 4 was the introduction of a suitably defined Hilbert space of analytic functions on which the "absorptive amplitude" turned out to be a positive operator of the Hilbert-Schmidt type. The use of these Hilbert space techniques was essentially local: the domains $\omega$ in the definition of $\mathcal{H}_\omega$ [see (3.26)] were relatively compact subdomains of the domains of holomorphy $\Omega$. The measures $\lambda$ were also rather arbitrarily taken to be Lebesgue measures.

We can now ask the question whether the initial positivity condition (3.25) can be formulated in a form that would - at least partially - respect analyticity (that is locality and the spectral condition) in a more explicit way. The answer is obviously to be sought in a suitable choice of the Hilbert space $\mathcal{H}_\omega(\mu)$ of analytic "test functions". Here $\mu$ denotes the set of measures which are to replace the Lebesgue measure in formula (3.26). The most natural choice seems to be $\omega = \Omega = \Omega_n$; the set of envelopes of holomorphy $\Omega_n$, and

$$d\mu_n = e^{-\phi_n} d\lambda_n, \quad (n = 1, 2, 3, \ldots) \quad (3.30)$$

(compare Hörmander 26), Ch. IV), with $\phi_n$ some real, let us say continuous, function in $\Omega_n$ such that

$$\int_{\Omega_n} A_{nn}(p_n, p_n) d\mu_n < \infty \quad (3.31)$$
Thanks to the (appropriately generalized) formula (3.27b), the last condition namely automatically ensures that the positive operator $A_N$ associated to the $N \times N$ matrix $(\tilde{a}_m^*)$ has a finite trace for any finite $N$, and hence that $A_N$ is the diagonalizable Hilbert-Schmidt type. For a given field such a choice of measures is always possible: one only has to choose the functions $\varphi_n$ of sufficiently rapid increase near the boundary of $\Omega_n$ (including points at infinity) (compare Hörmander, loc. cit.). One can then obviously choose the $\varphi_n$ also in such a way that the operator $A^\omega$ is of finite trace; hence the representation (3.28) is valid for all $n, m$, since the fundamental property (3.27a) of a Bergman-Hilbert space is - with a slight modification - preserved also in this case. Thus we get the

**THEOREM 4**.

Let the set of "absorptive amplitudes" satisfy the positivity condition (3.25). Then there exists a double sequence of functions $f_{m^\nu} \in \mathcal{D}(\Omega_n)$ ($\nu = 1, 2, 3, \ldots ; n = 1, 2, 3, \ldots$) such that the representation (3.28) is valid in $\Omega_n \times \Omega_n$ for all $n$ and $m$ in the sense of uniform convergence.

What we would still like to achieve is to find systems of measures $\mu_n$ such that every positive operator $A$ with finite trace acting on $\mathcal{D}(\Omega) \cap L^2(\Omega, \mu)$ gives rise to a system of $A_{nm}$'s with boundary values satisfying the initial physical conditions (3.25). For that purpose it is necessary and sufficient that the $A_{nm}$'s so defined do not increase faster than an inverse power of the distance to the boundary when approaching their physical boundary values (compare, e.g., Streater and Wightman 1, Theorem 2, or Epstein 19) - appropriate modifications of the asymptotic behaviour at infinity are to be made in the case of the Haag-Araki theory. Now the worse possible behaviour of an analytic function $f \in \mathcal{D}(\Omega) \cap L^2(\Omega, \mu)$ near a boundary point of $\Omega$ is determined - as seen by repeating the derivation of the formulas (3.6) and (3.27) in this slightly more general case - (compare 23, Ch. IV) - by the local behaviour of the inverse "weight function" $e^{\varphi}$. Thus $\varphi_n$ should essentially behave in $\Omega_n$ as the upper bound of moduli $|F_n|$ of the set $\mathcal{F}$.
of all the $n$ point functions satisfying the conditions of the linear program with some fixed growth properties in their primitive domain of analyticity. In other words $\varphi_n$ should be chosen as the (maybe somewhat smeared out) plurisubharmonic function

$$\varphi_n(p_n) = \sup_{F_n \in \mathcal{F}} \ln |F_n(p_n)| = \ln M_n(p_n).$$

Unfortunately, neither the envelopes of holomorphy $\Omega_n$ nor the functions $M_n$ are explicitly known in all of $\Omega_n'$. The situation can be remedied - at least partially - by replacing in the above considerations the holomorphy envelopes $\Omega_n$ by the corresponding primitive domains $\Omega_n^0$ (containing a finite complex neighbourhood of the real points of coincidence). As to the $M_n$'s, although known only in the initial tubes, they can also be extended to $\Omega_n^0$ with the help of the edge of the wedge theorem using an appropriate trick.

These last sketchy observations require a more detailed investigation and will have to be treated elsewhere. Let us only stress here, as a final remark, that the above methods can be applied - hopefully with more profit - also to the set of Wightman functions in $x$ space.

4. TWO EXAMPLES.

As an illustration of the expounded theory let us consider first the case when $A$ is of the form

$$A(p, q) = A(p - q). \quad (4.1)$$

The Wightmann two-point function in $x$ space $A(x - y) = (\Omega, A(x) A(y))$ is such an example (we have to set $x = p$, $y = q$).

To be contained in a forthcoming paper by Epstein and Glaser.
The function \( A(p - q) = A(2i \text{Im} p) \) does not depend on the real part of \( p \), hence the diagonal plane \( \mathbb{D}_{2N} = \mathbb{R}_N \oplus i \mathbb{R}_N \) actually reduces to its imaginary subspace \( i \mathbb{R}_N \). If we put \( p - q = z = x + iy \), the differential form of the positivity condition becomes:

\[
\sum \frac{\partial^\alpha - \partial^\beta}{\partial x^{\alpha} \partial y^{\beta}} A(iy) \geq 0 \quad . \tag{4.2}
\]

From Theorem 3 it then follows:

**COROLLARY 1.**

If a distribution \( f(y) = A(iy) \in \mathcal{S}'(\mathbb{R}) \), where \( B \) is an open set in \( \mathbb{R}_N \), satisfies condition (4.2) in \( B \), then \( f \) is the restriction to the imaginary plane \( \{ x = 0 \} \) of a function \( A(x + iy) \) analytic in the tube \( \mathcal{T}_B = \{ z = x + iy \in \mathbb{C}_N : y \in B \} \).

Let us call the set \( B = \{ z : \text{Re} z = 0, \text{Im} z \in B \} \) the "generating set" of \( A \). From Theorem 2, we then conclude:

**COROLLARY 2.**

Let \( B_1 \subset B_2 \) be two connected open sets \( \subset \mathbb{R}_N \), let \( \hat{B}_i = \{ z \in \mathbb{C}_N : \text{Re} z = 0, \text{Im} z \in B_i \} \) and \( \mathcal{T}_{\hat{B}_i} = \{ z \in \mathbb{C}_N : \text{Im} z \in B_i \} \). If \( A(p - q) = A(z) \) satisfying the positivity condition in \( \mathcal{T}_{\hat{B}_1} \) in the form (4.2) is analytic in a neighbourhood of the set \( B_2 \), then it is also analytic in the tube \( \mathcal{T}_{\hat{B}_2} \).

The integral form of the positivity condition can be cast into the following form:

\[
\int A(x - x' + iy) \overline{f}(x) f(x') \, dx \, dx' \geq 0
\]

for all \( y \in B \) and all \( f \in \mathcal{S}(\mathbb{R}_N) \) . \( \tag{4.3} \)
This has landed us in the very well-known theory of functions of positive type studied by Bochner and Schwartz and applied to field theory by Wightman.

Our second example will be an application to the two-body scattering amplitude. But before discussing it we shall have to state the following rather trivial

**LEMMA 1**

The positivity conditions A), B) and C) are invariant under an analytic substitution of variables $p = Tu$, $q = Tv$. Here $T$ is an analytic mapping from $\omega$ into $\Omega$, where $\omega$ is a domain in $\mathbb{C}_M$, and $\Omega \in \mathbb{C}_N$ the domain of definition of $\Lambda$ (in general $M \neq N$).

The proof is immediately obtained by looking at the "diagonal" representation of $A$. If we denote $A(Tu, Tv) = \hat{A}(u, \bar{v})$ and $f_v(Tu) = \hat{f}_v(u)$ one gets:

$$\hat{A}(u, \bar{v}) = \sum_v \hat{f}_v(u) \bar{f}_v(v).$$

From here, the conditions in the forms A) and C) with $p, q$ replaced by $u, v$ immediately follow.

**Note.**

Being an inequality, the positivity condition is determined only up to a factor. Indeed, if we replace $\Lambda$ by $F(p) \Lambda(p, \bar{q}) F(q) = \Lambda(p, \bar{q})$, where $F$ is any function analytic in $\Omega$ such that $F \neq 0$, nothing will change. We also want to warn the reader that the set of functions $f_v$ which diagonalizes $\Lambda$ is by no means unique.

We are now ready to study the absorptive part of the scattering amplitude of a process

$$A(k_1, m_1) + B(k_2, m_2) = A(k_3, m_1) + B(k_4, m_2).$$
where the four-momenta and masses of the two scalar particles involved are indicated in brackets. In agreement with the notational conventions used in (2.5) and (2.6) we have

$$\Lambda(k_3, k_4, k_2) = \Lambda_0(p, q)$$

with $\sigma = k_1 + k_2 = -k_3 - k_4$ and $k_{1,2} = \sigma/2 \pm q$, $k_{3,4} = -(\sigma/2 \pm p)$. The (complex) mass shell manifold is given by the equations

$$k_1^2 = k_2^2 = m_1^2, \quad k_2^2 = k_4^2 = m_2^2.$$ 

If we fix $\sigma$ in the form $\sigma = (\sqrt{s} \cos \theta, 0)$ with $s \geq (m_1 + m_2)^2$, then the resulting manifold can be parametrized as follows

$$p = (A, Rx), \quad q = (A, Ry), \quad \vec{x}^2 = \vec{y}^2 = 1 \quad (4.4)$$

where $A$ and $R$ are two real constants depending only on $s$ and the masses, and $\vec{x}$ and $\vec{y}$ very independently on the unit sphere. Since the particles are supposed to be scalar, $A$ is - at least on the mass shell - a Lorentz invariant function and hence depends only on $s$ and the scalar product $\vec{x} \cdot \vec{y}$. Therefore, without loss of information, we may specialize (4.4) to

$$p = (A, R \cos u, R \sin u, 0) = Tu$$
$$q = (A, R \cos v, R \sin v, 0) = Tv \quad (4.5)$$

and we get

$$\Lambda_0(Tu, Tv) = F(\cos(u - v)) \quad (4.6)$$

$T$ is evidently an analytic mapping, so Lemma 1 may be applied and therefore also Corollaries 1 and 2. Denoting by $\vec{\theta} = u - v = \vec{\theta}_1 + i \vec{\theta}_2$ the scattering angle we can conclude that the "generating set" of $A$ is a purely imaginary interval $I = \{ \vec{\theta} : \vec{\theta}_1 = 0, \vec{\theta}_2 \in I \}$. The interval $I$ has to contain the
origin since the origin corresponds to physical points, I is also symmetrical about the origin because $A$ is an even function of $\mathbf{v}$. Therefore the tube $T = \{ \mathbf{v} : -\alpha < \text{Im} \mathbf{v} < +\alpha \}$. The image of this strip in the variable $z = \cos \mathbf{v}$ is the ellipse with foci at $z = \pm 1$ and the major semi-axis $a = \text{ch} \alpha$ introduced into physics by Lehmann 21), while the image of the set $I$ is the real interval $1 \leq z < a$, with $a = \text{ch} \alpha$. Thus we have proved the theorem discovered by Jin and Martin 28).

**COROLLARY 2'.**

If the absorptive part of the scattering amplitude of two scalar particles is analytic for fixed $s$ in a neighborhood of the real interval $1 \leq z < a$, where $z = \cos \mathbf{v}$, then it is analytic also in the whole Lehmann ellipse with the major semi-axis $a$.

This fact can be stated also in the differential form of Corollary 1.

**COROLLARY 1'.**

If a distribution $F(x) = F(\text{ch} y) \in \mathbb{S}'(-\alpha < y < +\alpha)$ satisfies in $-\alpha < y < +\alpha$ the set of inequalities

$$
\sum_{n=0}^{\infty} \frac{\partial^n}{\partial y^n} F(\text{ch} y) \sum_{\alpha + \beta = n} a_{\alpha} \overline{a_{\beta}} \geq 0
$$

for all $\alpha \in \mathbb{C}$ such that $a_{\alpha} = 0$ for all $\alpha >$ some $N$, then $F$ is the restriction of a function $F(z)$ analytic in the Lehmann ellipse

$$
|z - 1| + |z + 1| < 2a = 2 \text{ch} \alpha.
$$

The inequalities (4.7) can be put, in principle, into a form involving only derivatives $\frac{\partial^n p(x)}{dx^n}$. What we want to show is that (4.7) implies the inequalities:
\[ \frac{d^n F(z)}{dz^n} \geq 0 \quad \text{for all} \quad 1 \leq Z < a \quad \text{and} \quad n = 0, 1, 2, \ldots \quad (4.8) \]

used extensively by Martin 6).

Instead of manipulation the expression (4.7) directly we shall start from the integral condition (4.3) applied to the variable \( \psi \) [which is a consequence of (4.7)]*).

The image of the strip \( -\alpha < \text{Im} \psi < \alpha \) in the complex plane of the variable \( \xi = e^{i\psi} \), \( z = \frac{1}{2}(\xi + \xi^{-1}) \), is the corona \( e^{-\alpha} < |\xi| < e^{\alpha} \). Since \( F \) is analytic there, it can be expanded into a convergent Laurent series

\[ F = \sum_{v=0}^{\infty} a_v \frac{1}{\xi^v + \xi^{-v}} \quad (4.9) \]

The last form follows from the symmetry of \( F \) under the substitution \( \xi \to \xi^{-1} \). Let us apply to (4.9) the integral inequality (4.3) by substituting in it \( x = \psi \), \( x' = \psi \), \( y = \psi' = 0 \), \( f = e^{i\psi} \xi \) and integrate from 0 to \( 2\pi \). We get

\[ a_v \geq 0 \quad \text{for all} \quad v = 0, 1, 2, \ldots \]

The last inequality implies (4.8) for \( n = 0 \). If we show that \( \frac{dF}{dz} \) can also be represented by a series of the form (4.9) with the coefficients \( a_v \) all positive, the inequality (4.8) will follow by induction. But this is a consequence of the identity

\[ \frac{d}{dz} \left( \xi^v + \xi^{-v} \right) = v \frac{\xi^v - \xi^{-v}}{\xi - \xi^{-1}} = v \sum_{\mu=0}^{v-1} \xi^{v-2\mu} \quad (4.10) \]

* The following proof is due to Epstein. The author would like to thank Dr. Epstein for the permission to include it in this paper.
The termwise differentiation of the series (4.9) and a rearrangement of terms shows namely, by virtue of (4.10), that the coefficients \( a^i \) are positive linear combinations of the coefficients \( a^0 \).

As the final comment, let us remark that the inequalities (4.8) are weaker than the set of inequalities (4.7). While (4.7) implies, according to the general theory, analyticity in the whole Lehmann ellipse, the inequalities (4.8) imply only analyticity in the disc \(|z - 1| < a\) with positive coefficients of the corresponding power series expansion. The last assertion follows from the Bernstein theorem (compare, e.g., 29).

**ACKNOWLEDGEMENTS**

The author would like to thank his colleagues Dr. D. Bessis, Dr. A. Martin and Dr. R. Stora for illuminating discussions. His special thanks are due to Dr. H. Epstein for suggestions in connection with the proof of Theorem 3, the permission to include his proof of the inequality (4.8) and many other critical remarks.
