# ANALYSIS OF A PROTOTYPICAL MULTISCALE METHOD COUPLING ATOMISTIC AND CONTINUUM MECHANICS 

Xavier Blanc ${ }^{1}$, Claude Le Bris ${ }^{2,3}$ and Frédéric Legoll ${ }^{2,3,4}$

#### Abstract

In order to describe a solid which deforms smoothly in some region, but non smoothly in some other region, many multiscale methods have recently been proposed. They aim at coupling an atomistic model (discrete mechanics) with a macroscopic model (continuum mechanics). We provide here a theoretical ground for such a coupling in a one-dimensional setting. We briefly study the general case of a convex energy, and next concentrate on a specific example of a nonconvex energy, the LennardJones case. In the latter situation, we prove that the discretization needs to account in an adequate way for the coexistence of a discrete model and a continuous one. Otherwise, spurious discretization effects may appear. We provide a numerical analysis of the approach.

## 1. Introduction

Traditionally, mechanics makes use of a continuum description of matter [9, 15]. However, when nanoscale phenomena arise, the atomistic nature of material cannot be ignored: for instance, to understand how dislocations appear and propagate under a nanoindenter, one has to describe the deformed atomistic lattice. The situation is the same when the material is subjected to singular body forces, or is likely to break because of extensional forces. In all these examples, an appropriate model to describe the localized phenomena is the atomistic model, in which the solid is considered as a set of discrete particles interacting through given interatomic potentials.

Nevertheless, the size of the materials that can be simulated by only resorting to an atomistic description is very small in comparison with the size of the materials one is interested in. Indeed, for some phenomena we have mentioned above, it is not possible to make accurate computations by just considering a small piece of material, because large scale or bulk effects have to be accounted for. For instance, crack propagation depends on the far stress field (so there is an influence of the coarse scale onto the fine scale), and, at the same time, when crack propagates, it creates stress waves that modify the far stress field (so there is also a feedback influence of the fine scale onto the coarse scale).

[^0]Fortunately, in the situations we have considered above, the deformation is smooth in the major part of the solid. Hence, a natural idea is to try to take advantage of both models, the continuous one and the atomistic one, by coupling them. The atomistic model is used in the zone where the deformation is expected to be non smooth, while the continuum description is used everywhere else. Many methods following this paradigm have been proposed and employed on realistic and complex situations: see [18,25,26] for some variational approaches (based on global minimizers), and [7] for time-dependent methods based on hybrid Hamiltonians. Notice that alternative ways, consisting in the approximation of the variational problems with a $\Gamma$-limit approach [5], or considering local minimizers instead of global ones [11], have also been considered.

We consider here a prototypical example of a variational method that couples a fine scale model in one zone with a coarse-grained model in another zone. This example is a toy-model for more advanced methods such as the Quasi-Continuum Method $[12,16,18-22]$. At least from the theoretical standpoint, a first key issue in the method is the consistency of the two models. Indeed, if the solution to be determined is smooth, then the solution given by the coarse-grained model should be the same as that given by the fine scale model, within an error controlled by the discretization parameters. A second issue is the adaptivity in the determination of the zones: we need to know where to use one model rather than the other one. Several multiscale methods that we have mentioned above include such an adaptation procedure, that seems however to lack from a rigorous basis.

The present work aims at giving such a theoretical basis for the micro-macro variational approach under study. The setting is one-dimensional. It is a clear limitation of the work. We have not been able to extend our analysis to the three-dimensional mechanically relevant case and it is not clear to us, even at the formal level, which of the results contained here may survive in the three-dimensional setting. We however hope that the present study will contribute to a better understanding of the fundamental issues.

### 1.1. The atomistic and continuum problems

Let us consider a one dimensional material, occupying in the reference configuration the domain $\Omega=(0, L)$. Let $u$ be the deformation, i.e. the map defined on $\Omega$ such that $u(x)$ is the position, in the current configuration, of a material point that is at $x$ in the reference configuration. This material is subjected to body forces $f$ and to Dirichlet boundary conditions $u(0)=0$ and $u(L)=a>0$.

The solid will be described at two different space scales:

- the fine scale, at which the atomistic nature of the matter is taken into account;
- the coarse scale, which corresponds to a continuum description.

At the fine scale, the solid is considered as a set of $N+1$ atoms, whose current positions are $\left(u^{i}\right)_{i=0}^{N}$. The energy of the system is modelled by nearest-neighbour interactions:

$$
\begin{equation*}
E_{\mu}\left(u^{0}, \ldots, u^{N}\right)=h \sum_{i=0}^{N-1} W\left(\frac{u^{i+1}-u^{i}}{h}\right)-h \sum_{i=0}^{N} u^{i} f(i h) \tag{1}
\end{equation*}
$$

In this equation, $W$ is the interaction potential between atoms and $h$ is the atomic lattice parameter, which is linked to the number of atoms and the size of the solid by $L=N h$. The potential $W$ is normalized so that its minimum is attained at 1 . The atomistic equilibrium configuration, denoted by $u_{\mu}=\left(u_{\mu}^{0}, \ldots, u_{\mu}^{N}\right)$, is the solution ${ }^{1}$ of the variational problem

$$
\begin{equation*}
I_{\mu}=\inf \left\{E_{\mu}\left(u^{0}, \ldots, u^{N}\right),\left(u^{0}, \ldots, u^{N}\right) \in X_{\mu}(a)\right\} \tag{2}
\end{equation*}
$$

where the minimizing space is

$$
\begin{equation*}
X_{\mu}(a)=\left\{\left(u^{0}, \ldots, u^{N}\right), u^{0}=0, u^{N}=a, \forall i, u^{i+1}>u^{i}\right\} . \tag{3}
\end{equation*}
$$

[^1]Recall that a deformation $u$ of the solid is mechanically admissible only if it is an injective function. As we work in a one-dimensional setting and impose $u^{N}=a>0=u^{0}$, a necessary and sufficient condition for injectivity is that $u$ is increasing, thus the constraint $u^{i+1}>u^{i}$ in (3).

On the other hand, at the coarse scale, the solid deformation is described by a map $u: \Omega \rightarrow \mathbb{R}$ chosen in the variational space

$$
\begin{equation*}
X_{M}(a)=\left\{u \in H^{1}(\Omega), u(0)=0, u(L)=a, u \text { is increasing on } \Omega\right\} \tag{4}
\end{equation*}
$$

The energy of the system reads

$$
\begin{equation*}
E_{M}(u)=\int_{\Omega} W\left(u^{\prime}(x)\right) \mathrm{d} x-\int_{\Omega} f(x) u(x) \mathrm{d} x \tag{5}
\end{equation*}
$$

We will give below (see Sect. 1.4.1) more precise assumptions to ensure that the energy is well-defined as soon as $u \in H^{1}(\Omega)$. The equilibrium configuration, denoted by $u_{M}(x)$, is a solution of the variational problem

$$
\begin{equation*}
I_{M}=\inf \left\{E_{M}(u), u \in X_{M}(a)\right\} \tag{6}
\end{equation*}
$$

Remark 1.1. In a two- or three-dimensional setting, some sufficient conditions for the injectivity of a map are given in [9], pp. 222-231.

The question we address in the present work concerns the approximation of problem (2). Indeed, for any deformation $u$ of the material, the energy is given by (1), but the number of atoms to be considered in the sum, typically of the order $10^{23}$ in a macroscopic sample of material, makes the computation of (1) untractable in practice.

When the deformation $u$ is regular and fixed independently of $h$, it has been shown in [4] that the atomistic energy $E_{\mu}(u(0), u(h), \ldots, u(N h))$ converges to $E_{M}(u)$ when the atomic lattice parameter $h$ goes to 0 and the number of atoms goes to infinity such that $N h$ remains constant, $N h=L$. This result ensures the above mentioned consistency of the two descriptions, (1) on the one hand and (5) on the other hand, and also provides with an economical way to compute the sum (1), namely by approximating the integral (5). It remains that, when deformations that are expected to play a role are not regular enough to allow for the above convergence, the only way to compute the energy seems to be resorting to the atomistic expression (1). An economical approach is the coupled approach we consider in the present work.

### 1.2. A coupled problem

Let $\Omega_{M} \subset \Omega$ be an open subset of the solid in which the deformation $u$ is supposed to be smooth enough so that the atomistic expression of the energy may be replaced by the continuum one. Throughout this article, we suppose that $\Omega_{M}$ satisfies the following property:

Property 1.1. For simplicity, we suppose

$$
\begin{equation*}
\Omega_{M}=\bigcup_{j=1}^{J}\left(a_{j} h, b_{j} h\right) \subset \Omega \tag{7}
\end{equation*}
$$

with $a_{j}, b_{j} \in\{0, \ldots, N\}, a_{j}<b_{j}<a_{j+1}$, and where the number $J$ of connected components of $\Omega_{M}$ is bounded by $\mathcal{N}_{c c}$, where $\mathcal{N}_{c c}$ is a given fixed parameter (see Fig. 1).

## Continuum mechanics Atomistic model

Figure 1. Partition of $\Omega$ into a regular zone $\Omega_{M}$ where the continuum mechanics model is used, and a singular zone $\Omega_{\mu}$ where the atomistic model is used. By definition, we have $a_{j} h \in \Omega_{\mu}$ and $b_{j} h \in \Omega_{\mu}$.

Definition 1.1. Let us denote by

$$
\begin{equation*}
\mathbb{N}_{\mu}=\left\{i \in\{0, \ldots, N-1\} ; i h \in \Omega_{\mu} \text { and } i h+h \in \Omega_{\mu}\right\} \tag{8}
\end{equation*}
$$

the set of indices $i$ such that both atoms $i$ and $i+1$ are contained in $\Omega_{\mu}$.
With (7), we can see that $\mathbb{N}_{\mu}=\cup_{j=1}^{J-1}\left\{b_{j}, \ldots, a_{j+1}-1\right\}$.
For any partition $\Omega=\Omega_{M} \cup \Omega_{\mu}$, the solid deformation can be described by an element of the hybrid (atomistic/continuum) space

$$
X_{c}\left(a, \Omega_{M}\right)=\left\{\begin{array}{c}
u ; u_{\mid \Omega_{M}} \in X_{W}\left(\Omega_{M}\right), u_{\mid \Omega_{\mu}} \text { is the discrete set of variables }\left(u^{i}\right)_{i h \in \Omega_{\mu}},  \tag{9}\\
u\left(\left(a_{j} h\right)^{+}\right)=u^{a_{j}}, u\left(\left(b_{j} h\right)^{-}\right)=u^{b_{j}} \\
u \text { is increasing on } \Omega
\end{array}\right\}
$$

where $X_{W}\left(\Omega_{M}\right)$ is some functional space that depends on the potential $W$ and that will be made precise below. We have written down the boundary conditions supposing that 0 and $L$ are in $\overline{\Omega_{M}}$ (otherwise, adequate and simple modifications are in order). The last line in (9) is equivalent to the injectivity of $u$.

A natural idea is to first fix $\Omega_{M}$, next, for each $u \in X_{c}\left(a, \Omega_{M}\right)$, to define the energy of the deformed system by

$$
\begin{equation*}
E_{c}(u)=h \sum_{i \in \mathbb{N}_{\mu}} W\left(\frac{u^{i+1}-u^{i}}{h}\right)-h \sum_{i, i h \in \Omega_{\mu}} u^{i} f(i h)+\int_{\Omega_{M}} W\left(u^{\prime}\right)-u f \tag{10}
\end{equation*}
$$

and finally to state a minimization problem at $\Omega_{M}$ fixed,

$$
\begin{equation*}
I_{c}\left(\Omega_{M}\right)=\inf \left\{E_{c}(u), u \in X_{c}\left(a, \Omega_{M}\right)\right\} \tag{11}
\end{equation*}
$$

The point is unfortunately that $\Omega_{M}$ is difficult, or even impossible, to determine in advance. In fact, it depends on the minimizer $u_{\mu}$ of (2) as it should, vaguely stated, consist of all the zones of regularity of $u_{\mu}$ (in order to allow for both an economical and correct evaluation of the energy), and $u_{\mu}$, which is the reference (ideal) solution, cannot be computed. In the case of a convex interaction potential $W$, it is possible to explicitly determine the zone $\Omega_{M}$ of regularity of $u_{\mu}$. Consequently:
(1) when the atomistic solution $u_{\mu}$ is smooth in some region of $\Omega$, the set $\Omega_{M}$ is a domain embedding this region;
(2) the minimization problem (11) is theoretically well posed;
(3) an algorithm can be proposed to compute a solution of (11);
(4) the error between the computed solution and the reference solution $u_{\mu}$ may be estimated.

Section 1.4 briefly presents the main mathematical statements corresponding to the above claims. On the other hand, we deal in Section 2 with a nonconvex interaction potential $W$, which is the mechanically relevant case.

The examination is performed on a special case of a nonconvex elastic energy density $W$, that is the LennardJones case. Then, the minimization problem set with energy (10) is ill-posed. Both the continuum model and the atomistic model are unable to sustain traction (see Sects. 2.1 and 2.2), and a fracture appears for any extensional load. With the coupled model, a spurious effect appears in the energy functional (10): the comparison of the energy of a fracture in the zone $\Omega_{\mu}$ with that of the same fracture in the zone $\Omega_{M}$ shows that the energetically most favorable situation is the latter (see Sect. 2.3). This rules out the possibility of ever self-consistently adapting the partition to the singularities of the deformation and leads us to a modification of the coupled energy: instead of defining it by (10), we define it by

$$
\begin{equation*}
E_{\bmod }(u)=h \sum_{i \in \mathbb{N}_{\mu}} W\left(\frac{u^{i+1}-u^{i}}{h}\right)-h \sum_{i, i h \in \Omega_{\mu}} u^{i} f(i h)+\int_{\Omega_{M}} W^{h}\left(u^{\prime}\right)-u f \tag{12}
\end{equation*}
$$

with

$$
W^{h}(r)=W(r)+\sqrt{h} \tau\left(r-r_{0}\right)
$$

In the latter relation, $r_{0}$ is some threshold parameter (to be made precise below) and the function $\tau$, which does not depend on $h$, is a regularization of the function $t \in \mathbb{R} \mapsto t_{+}=\max (0, t)$. The minimization problem associated to the energy (12) reads

$$
\begin{equation*}
I_{\bmod }\left(\Omega_{M}\right)=\inf \left\{E_{\bmod }(u), u \in X_{c}\left(a, \Omega_{M}\right)\right\} \tag{13}
\end{equation*}
$$

This modification remedies to the above obstruction, and is also consistent both with the atomistic model energy (1) and the continuum mechanics model energy (5). Again, as in the convex case, $\Omega_{M}$ should consist of all the zones of regularity of the reference solution $u_{\mu}$. In Sections 2.4 and 2.5 , we show that this set can be approximated by a set (again denoted by $\Omega_{M}$ ) that can be computed. We then show that the solution of the so-obtained problem (13) is a converging approximation of the reference solution $u_{\mu}$, and that, when the solid is subjected to an extensional load, the atomistic domain $\Omega_{\mu}=\Omega \backslash \Omega_{M}$ contains the fracture.

### 1.3. Outline of the article

We wish to point out that the main purpose of the present work is to study the coupled (atomistic/continuum) models (11) and (13), in the nonconvex case, because this is the mechanically relevant case and the most interesting case from numerical analysis standpoint. But before going to this, we need to lay some groundwork. First, for the sake of comparison, we study in Section 1.4 the continuum, the atomistic and the coupled problems in the convex case. Next, in the nonconvex case, we need to study the continuum and the atomistic problems separately (this is performed in Sects. 2.1 and 2.2).

All these problems of Sections 1.4, 2.1, 2.2 have been addressed before in the literature (see [9,13,15, 23, 24]). But in the absence of a systematic mathematical study and with a view to self-consistency, we have chosen to still present them in the following way. For the case of a convex energy (Sect. 1.4), since the analysis is quite simple, the main results will be stated without any proofs. The detailed arguments and some additional comments can be found in [3,14]. In the nonconvex case, for the continuum and atomistic problems, we again state the main results, but postpone the proofs until appendices A, B and C. The reader, either familiar with such studies, or not mathematically oriented, may directly proceed to the heart of the matter, namely Sections $2.3,2.4$ and 2.5 , where the most original results are discussed.

We collect now the main results of our work. At this stage, they are somewhat vaguely stated, but they will be made precise below.
(1) The atomistic problem (2) and the continuum problem (6) are well posed in the convex case (see Lem. 1.1) and in the Lennard-Jones case (see Thms. 2.1 and 2.3).
(2) In the convex case,

- for any $\Omega_{M} \subset \Omega$, the coupled problem (11) is well posed (see Lem. 1.1);
- it is possible to define $\Omega_{M}$ in such a way that the solution of the coupled problem (11) is a converging approximation of the solution of the atomistic problem (2) (see Def. 1.3 and Thm. 1.1).
(3) In the Lennard-Jones case,
- for any $\Omega_{M} \subset \Omega$, the coupled problem (13) is well posed (see Thm. 2.5) and if a fracture appears, it is located in $\Omega_{\mu}$;
- it is possible to define $\Omega_{M}$ in such a way that the solution of the modified coupled problem (13) is a converging approximation of the solution of the atomistic problem (2) (see Thm. 2.6 and Def. 2.1).

### 1.4. The case of a convex elastic energy density $W$

Let us first make precise the space $X_{c}\left(a, \Omega_{M}\right)$ defined in (9). In this section, we set $X_{W}\left(\Omega_{M}\right)=H^{1}\left(\Omega_{M}\right)$.

### 1.4.1. Properties of the variational problems

In this subsection, we provide conditions ensuring that the variational problems we consider are well-posed. Let us begin with a definition

Definition 1.2. We suppose that the body forces $f$ satisfy

$$
\begin{equation*}
f \in \mathcal{C}^{0}(\bar{\Omega}) \tag{14}
\end{equation*}
$$

Let us define $F_{M}$ and $F_{\mu}$ by

$$
\begin{gather*}
\forall x \in \Omega, F_{M}(x)=\int_{0}^{x} f(s) \mathrm{d} s  \tag{15}\\
F_{\mu}^{0}=0 \quad \text { and } \quad \forall i \in\{1, \ldots, N\}, F_{\mu}^{i}=h \sum_{j=1}^{i} f(j h) \tag{16}
\end{gather*}
$$

For any $\Omega_{M}$, we also define a function $F_{c}$ as follows: on $\Omega_{M}$, we set, for all $x \in\left(a_{j} h, b_{j} h\right), j \in\{1, \ldots, J\}$,

$$
\begin{equation*}
F_{c}(x)=\int_{\Omega_{M} \cap(0, x)} f(s) \mathrm{d} s+h \sum_{k=1}^{j-1}\left(f\left(b_{k} h\right)+f\left(b_{k} h+h\right)+\ldots+f\left(a_{k+1} h\right)\right) \tag{17}
\end{equation*}
$$

whereas, on $\Omega_{\mu}$, for all $j \in\{1, \ldots, J-1\}$, we set, for all $i \in\left\{b_{j}, \ldots, a_{j+1}\right\}$,

$$
\begin{equation*}
F_{c}^{i}=\int_{\Omega_{M} \cap(0, i h)} f(s) \mathrm{d} s+h \sum_{k=1}^{j-1}\left(f\left(b_{k} h\right)+\ldots+f\left(a_{k+1} h\right)\right)+h \sum_{q=b_{j}}^{i} f(q h) \tag{18}
\end{equation*}
$$

We note that $F_{c}$ is continuous on $\Omega_{M}$, continuous at $a_{j} h$, but not continuous at $b_{j} h$. In the sequel of this section, we assume that the elastic energy density $W$ satisfies

$$
\left\{\begin{array}{l}
W \in \mathcal{C}^{2}(\mathbb{R}),  \tag{19}\\
\exists \alpha>0, \quad \forall x \in \mathbb{R}, \quad \alpha \leq W^{\prime \prime}(x), \\
\exists \beta>0, \forall x \in \mathbb{R}, \quad\left|W^{\prime}(x)\right| \leq \beta|x-1|
\end{array}\right.
$$

Although $W$ is defined on $\mathbb{R}$, we need in fact to know $W(x)$ only for $x>0$, due to the injectivity constraint that is included in the variational spaces (3), (4) and (9). Let us set

$$
\begin{align*}
a_{M}^{*} & =\int_{\Omega}\left(W^{\prime}\right)^{-1}\left(W^{\prime}(0)+\sup _{\Omega} F_{M}-F_{M}(x)\right) \mathrm{d} x  \tag{20}\\
a_{\mu}^{*} & =h \sum_{i=0}^{N-1}\left(W^{\prime}\right)^{-1}\left(W^{\prime}(0)+\left(\sup _{0 \leq i \leq N-1} F_{\mu}^{i}\right)-F_{\mu}^{i}\right),  \tag{21}\\
a_{c}^{*} & =\int_{\Omega_{M}}\left(W^{\prime}\right)^{-1}\left(W^{\prime}(0)+\overline{F_{c}}-F_{c}(x)\right) \mathrm{d} x+h \sum_{i \in \mathbb{N}_{\mu}}\left(W^{\prime}\right)^{-1}\left(W^{\prime}(0)+\overline{F_{c}}-F_{c}^{i}\right), \tag{22}
\end{align*}
$$

where $\overline{F_{c}}=\sup \left(\sup _{x \in \Omega_{M}} F_{c}(x), \sup _{i \in \mathbb{N}_{\mu}} F_{c}^{i}\right)$. Then, we have:
Lemma 1.1 (existence and uniqueness of solutions). Let $\Omega_{M}$ be a fixed subdomain of $\Omega$. We assume that the elastic energy density $W$ satisfies (19) and that the body forces $f$ satisfy (14).

If $a>a_{M}^{*}$, then the continuum problem (6) has a unique minimizer $u_{M}$, which is in addition in $H^{2}(\Omega)$. If $a<a_{M}^{*}$, the problem (6) is not attained.

If $a>a_{\mu}^{*}$, then the atomistic problem (2) has a unique minimizer $u_{\mu}$. If $a \leq a_{\mu}^{*}$, then the problem (2) is not attained.

If $a>a_{c}^{*}$, then the coupled problem (11) has a unique minimizer $u_{c}$. If $a<a_{c}^{*}$, the problem (11) is not attained.

Before proceeding further, let us recall the Euler-Lagrange equation for (2). Under the assumption $a>a_{\mu}^{*}$, the constraint $u^{i+1}>u^{i}$ is not active, thus

$$
\begin{equation*}
\forall i \in\{1, \ldots, N-1\}, \quad W^{\prime}\left(\frac{u_{\mu}^{i}-u_{\mu}^{i-1}}{h}\right)-W^{\prime}\left(\frac{u_{\mu}^{i+1}-u_{\mu}^{i}}{h}\right)-h f(i h)=0 \tag{23}
\end{equation*}
$$

An equivalent formulation is easily obtained:

$$
\begin{equation*}
\forall i \in\{0, \ldots, N-1\}, \quad \frac{u_{\mu}^{i+1}-u_{\mu}^{i}}{h}=\left(W^{\prime}\right)^{-1}\left(\lambda_{\mu}-F_{\mu}^{i}\right), \tag{24}
\end{equation*}
$$

where $\lambda_{\mu}=W^{\prime}\left(\left(u_{\mu}^{1}-u_{\mu}^{0}\right) / h\right)$ and $F_{\mu}$ is defined by (16). With similar arguments, it can be shown that the minimizer $u_{c}$ of (11) satisfies

$$
\begin{align*}
& \forall x \in \Omega_{M}, \quad u_{c}^{\prime}(x)=\left(W^{\prime}\right)^{-1}\left(\lambda_{c}-F_{c}(x)\right), \\
& \forall i \in \mathbb{N}_{\mu}, \quad \frac{u_{c}^{i+1}-u_{c}^{i}}{h}=\left(W^{\prime}\right)^{-1}\left(\lambda_{c}-F_{c}^{i}\right), \tag{25}
\end{align*}
$$

where $\lambda_{c}=W^{\prime}\left(u_{c}^{\prime}(0)\right)$ (recall we have assumed $0 \in \overline{\Omega_{M}}$ ), the set $\mathbb{N}_{\mu}$ is defined by (8) and $F_{c}$ is defined by (17) and (18).

### 1.4.2. Definition of the partition

We now introduce a criterion in order to define the subdomain $\Omega_{M}$. Actually, due to the convexity of $W$, which allows for elliptic regularity results on the Euler-Lagrange equation (23), the singularities of the solution $u_{\mu}$ are solely linked to the singularities of the body forces $f$. So the subdomain $\Omega_{M}$ is simply the zone of regularity of $f$. The situation will be radically different in the Lennard-Jones case (see Def. 2.1).
Definition 1.3 (partition in the convex case). We assume that (14) is satisfied. Let $\kappa_{f}>0$. We say that the interval $(i h, i h+h)$ is a regular interval if $f \in W^{1,1}(i h, i h+h)$ with

$$
\forall x \in(i h, i h+h),|f(x)| \leq \kappa_{f} \quad \text { and } \quad \int_{i h}^{i h+h}\left|f^{\prime}(x)\right| \mathrm{d} x \leq h \frac{\kappa_{f}}{L}
$$

We define

$$
\Omega_{M}=\bigcup_{(i h, i h+h) \text { regular }}^{*}(i h, i h+h) \quad \text { and } \quad \Omega_{\mu}=\Omega \backslash \Omega_{M},
$$

where $\bigcup^{*}$ means that the point $\{i h\}$ is also included in $\Omega_{M}$ if both $(i h-h, i h)$ and $(i h, i h+h)$ are regular intervals.

By construction, $f$ and $f^{\prime}$ are bounded on $\Omega_{M}$ :

$$
\begin{equation*}
\|f\|_{L^{\infty}\left(\Omega_{M}\right)} \leq \kappa_{f} \text { and }\left\|f^{\prime}\right\|_{L^{1}\left(\Omega_{M}\right)} \leq \kappa_{f} \tag{26}
\end{equation*}
$$

In Definition 1.2, we have introduced the functions $F_{M}, F_{\mu}$ and $F_{c}$ (see (15), (16), (17) and (18)). An estimate of their difference is provided by the following lemma.

Lemma 1.2. We assume that the body forces satisfy (14) and (26). Then

$$
\begin{equation*}
\lim _{h \rightarrow 0} \sup _{k}\left|F_{M}(k h)-F_{\mu}^{k}\right|=0 \tag{27}
\end{equation*}
$$

and, for all $h$,

$$
\begin{align*}
& \forall k \text { s.t. } k h \in \Omega_{M},\left|F_{c}(k h)-F_{\mu}^{k}\right| \leq h \kappa_{f}\left(\mathcal{N}_{c c}+1\right), \\
& \forall k \text { s.t. } k h \in \Omega_{\mu},\left|F_{c}^{k}-F_{\mu}^{k}\right| \leq h \kappa_{f}\left(\mathcal{N}_{c c}+1\right) \tag{28}
\end{align*}
$$

### 1.4.3. Comparison of the atomistic problem and the coupled problem

In this subsection, we assume that the partition is defined according to Definition 1.3. We introduce:
Definition 1.4. The operator $\Pi_{c}: v_{\mu} \in X_{\mu}(a) \mapsto \Pi_{c} v_{\mu} \in X_{c}\left(a, \Omega_{M}\right)$ is the interpolation-on- $\Omega_{M}$ operator defined by

$$
\forall x \in \Omega_{M},\left(\Pi_{c} v_{\mu}\right)(x)=v_{r}(x), \quad \text { and } \quad \forall i h \in \Omega_{\mu},\left(\Pi_{c} v_{\mu}\right)^{i}=v_{\mu}^{i}
$$

where $v_{r}$ is the piecewise linear interpolate of $v_{\mu}$, at points $i h$, in $\Omega_{M}$.
The operator $\Pi_{\mu}: v_{c} \in X_{c}\left(a, \Omega_{M}\right) \mapsto \Pi_{\mu} v_{c} \in X_{\mu}(a)$ is the evaluation operator defined by

$$
\forall i h \in \Omega_{M},\left(\Pi_{\mu} v_{c}\right)^{i}=v_{c}(i h), \quad \text { and } \quad \forall i h \in \Omega_{\mu},\left(\Pi_{\mu} v_{c}\right)^{i}=v_{c}^{i}
$$

Next, for any $u \in X_{c}$, we define

$$
\begin{align*}
\|u\|_{L^{\infty}\left(X_{c}\right)} & =\max \left(\|u\|_{L^{\infty}\left(\Omega_{M}\right)}, \max _{i, i h \in \Omega_{\mu}}\left|u^{i}\right|\right)  \tag{29}\\
|u|_{W^{1, \infty}\left(X_{c}\right)} & =\max \left(\left\|u^{\prime}\right\|_{L^{\infty}\left(\Omega_{M}\right)}, \max _{i \in \mathbb{N}_{\mu}}\left|\frac{u^{i+1}-u^{i}}{h}\right|\right) \tag{30}
\end{align*}
$$

and for any $u \in X_{\mu}$,

$$
\begin{equation*}
\|u\|_{L^{\infty}\left(X_{\mu}\right)}=\max _{i \in[0, N]}\left|u^{i}\right| \quad \text { and } \quad|u|_{W^{1, \infty}\left(X_{\mu}\right)}=\max _{i \in[0, N-1]}\left|\frac{u^{i+1}-u^{i}}{h}\right| \tag{31}
\end{equation*}
$$

The main result for the comparison of the atomistic and the coupled problems in this convex case is the following:
Theorem 1.1. We assume (14), (19) and

$$
\begin{equation*}
a>a_{M}^{*}, \tag{32}
\end{equation*}
$$

where $a_{M}^{*}$ is defined by (20). We also assume that the partition $\Omega=\Omega_{M} \cup \Omega_{\mu}$ is defined according to Definition 1.3 for some $\kappa_{f}>0$. Let $\Pi_{c}$ and $\Pi_{\mu}$ be the operators defined in Definition 1.4.

Then there exist $h_{0} \leq 1$ (which depends on $\kappa_{f}$ ) and constants $C_{1}$ and $C_{i}\left(\kappa_{f}\right), i=2, \ldots, 5$, such that, for all $h \leq h_{0}$, problems (2) and (11) have unique minimizers, respectively denoted by $u_{\mu}$ and $u_{c}$. In addition these minimizers satisfy

$$
\left|u_{c}\right|_{W^{1, \infty}\left(X_{c}\right)} \leq C_{1} \quad \text { and } \quad\left|u_{\mu}\right|_{W^{1, \infty}\left(X_{\mu}\right)} \leq C_{1},
$$

and are at a distance of order $h$ from one another in the sense that

$$
\begin{align*}
\left|\left(\Pi_{\mu} u_{c}\right)-u_{\mu}\right|_{W^{1, \infty}\left(X_{\mu}\right)} \leq C_{2}\left(\kappa_{f}\right) h \kappa_{f},  \tag{33}\\
\left|u_{c}-\left(\Pi_{c} u_{\mu}\right)\right|_{W^{1, \infty}\left(X_{c}\right)} \leq C_{2}\left(\kappa_{f}\right) h \kappa_{f},  \tag{34}\\
\left\|\left(\Pi_{\mu} u_{c}\right)-u_{\mu}\right\|_{L^{\infty}\left(X_{\mu}\right)} \leq C_{3}\left(\kappa_{f}\right) h \kappa_{f},  \tag{35}\\
\left\|u_{c}-\left(\Pi_{c} u_{\mu}\right)\right\|_{L^{\infty}\left(X_{c}\right)} \leq C_{4}\left(\kappa_{f}\right) h \kappa_{f}, \tag{36}
\end{align*}
$$

while the energy infima also differ of an order $h$ :

$$
\begin{equation*}
\left|I_{c}\left(\Omega_{M}\right)-I_{\mu}\right| \leq C_{5}\left(\kappa_{f}\right) h \kappa_{f} \tag{37}
\end{equation*}
$$

The constant $C_{1}$ does not depend on $\kappa_{f}$, and the functions $\kappa_{f} \mapsto C_{i}\left(\kappa_{f}\right), i=2, \ldots, 5$, are bounded on any compact set.

Remark 1.2. The proof (not included herein for the sake of brevity) yields the following explicit expressions for the constants $C_{i}, i=1, \ldots, 5$ :

$$
\begin{gathered}
C_{1}=\frac{L}{4 \alpha}\|f\|_{L^{\infty}(\Omega)}+4 \frac{a}{L}, \quad C_{2}\left(\kappa_{f}\right)=\frac{2+\mathcal{N}_{c c}}{\alpha}\left(1+\frac{\beta_{K}\left(\kappa_{f}\right)}{\alpha}\right), \\
C_{3}\left(\kappa_{f}\right)=L C_{2}\left(\kappa_{f}\right), \quad C_{4}\left(\kappa_{f}\right)=C_{2}\left(\kappa_{f}\right) h+C_{3}\left(\kappa_{f}\right), \\
C_{5}\left(\kappa_{f}\right)=2 a+L\left(\beta C_{2}\left(\kappa_{f}\right)\left(C_{1}+1\right)+C_{3}\left(\kappa_{f}\right)\|f\|_{L^{\infty}(\Omega)}\right),
\end{gathered}
$$

where $\beta_{K}\left(\kappa_{f}\right)=\max _{K} W^{\prime \prime}\left(W^{\prime}(\cdot)\right)$.
Here, $K$ is the closed interval of center 0 and of radius $h_{0} \kappa_{f}\left(1+\mathcal{N}_{c c}\right)+\beta\left(C_{1}+1\right)$.
Remark 1.3. An alternative method to evaluate $u_{\mu}-u_{c}$ is based on the observation that minimizing $E_{\mu}$ over $X_{\mu}(a)$ is equivalent to minimizing $E_{c}$ over a finite element space $X_{c}^{h}\left(a, \Omega_{M}\right) \subset X_{c}\left(a, \Omega_{M}\right)$ of mesh size $h$, where the body force integral term is now computed by a numerical integration formula (namely, a Riemann sum). So standard results of FEM theory can be applied in order to obtain an $H^{1}$ estimate on $u_{\mu}-u_{c}$. However, obtaining $L^{\infty}$ estimates from such an argument is more tricky (see $[6,8,10,17]$ ).
Remark 1.4. In view of Remark 1.3, the atomistic problem can be seen as a continuum problem posed on a finite element space of mesh size $h$. Therefore the convergence of order $h$ for the "first derivative" of $u_{c}-u_{\mu}$ is sharp (see (33) and (34)). Using an argument à la Aubin-Nitsche, and assuming additionally that $W \in \mathcal{C}^{3}(\mathbb{R})$ and $f \in H^{2}\left(\Omega_{M}\right)$, one can improve (35) and (36) and show that, for $h$ small enough,

$$
\left\|\left(\Pi_{\mu} u_{c}\right)-u_{\mu}\right\|_{L^{\infty}\left(X_{\mu}\right)}+\left\|u_{c}-\Pi_{c} u_{\mu}\right\|_{L^{\infty}\left(X_{c}\right)} \leq C h^{2}
$$

for some constant $C$ that does not depend on $h$.

Figure 2. The Lennard-Jones potential (solid line) and its convex envelop (dashed line).

## 2. The Lennard-Jones case

In this section, the interaction potential is the Lennard-Jones potential

$$
\begin{equation*}
W_{\mathrm{LJ}}(r)=\frac{1}{r^{12}}-\frac{2}{r^{6}}, \tag{38}
\end{equation*}
$$

which attains its minimum at $1: W_{\mathrm{LJ}}(1)=\inf W_{\mathrm{LJ}}=-1$.
Let $W_{\mathrm{LJ}}^{* *}$ be the convex envelop of $W_{\mathrm{LJ}}$, and let us set

$$
r_{c}=\left(\frac{13}{7}\right)^{1 / 6} \approx 1.11
$$

such that $W_{\mathrm{LJ}}$ is convex on the interval $\left(0, r_{c}\right)$ and concave on $\left(r_{c},+\infty\right)$. We also define the functions

$$
\begin{align*}
\psi:\left(-\infty, W_{\mathrm{LJ}}^{\prime}\left(r_{c}\right)\right) \rightarrow\left(0, r_{c}\right) & \text { such that } \quad \psi \circ W_{\mathrm{LJ}}^{\prime}=\mathrm{Id}  \tag{39}\\
\varphi:\left(0, W_{\mathrm{LJ}}^{\prime}\left(r_{c}\right)\right) \rightarrow\left(r_{c},+\infty\right) & \text { such that } \quad \varphi \circ W_{\mathrm{LJ}}^{\prime}=\mathrm{Id} \tag{40}
\end{align*}
$$

For $x \leq 0$, we will also make use of the notation $\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}(x)=\psi(x)$, as there is in such a case no ambiguity. We denote by $H(t)$ the Heaviside function $(H(t)=0$ if $t<0, H(t)=1$ otherwise).

We use the Lennard-Jones potential as a prototype for a nonconvex interaction potential. One important feature allowing for the appearance of fracture is that $\lim _{r \rightarrow \infty} W_{\mathrm{LJ}}(r) / r=0$.

In Section 2.1, we study the continuum mechanics problem (6), and show that a fracture (a Dirac mass in the derivative of the deformation) appears for any extensional load. The atomistic model (2), studied in Section 2.2, exhibits the same behavior. For the sake of conciseness, and in order to concentrate on the coupled problem that will be dealt with in the subsequent sections, we have postponed the somewhat lengthy proofs of the main results of Sections 2.1 and 2.2 (namely Thms. 2.1, 2.2 and 2.3) to Appendices A-C. In Section 2.3, we study the coupled problem (11) where the energy is defined by (10). In Section 2.4, we study the modified coupled problem (13) with the energy (12). We then propose a way to build the atomistic-continuum partition (see Def. 2.1 below) such that the solution of the modified coupled problem approaches the solution of the atomistic problem. To build the partition, we will make use of a preliminary step: the determination of the solution of the continuum problem, a task which is assumed to be little demanding computationally in comparison with
the resolution of a problem with a discrete component. The situation is thus different from the convex case in which we only use the given body forces $f$, and not the solution of the continuum problem, to define the partition.

Before entering the details, let us point out that the analysis below is highly dependent on the one-dimensional setting we chose here. However, the fact that the most natural way to couple the atomistic and the continuum models creates some difficulties (see Sect. 2.3) is more general, and occurs also in higher dimensions.
Remark 2.1. The results of this section do not depend on the particular choice of the exponents that we have made in (38). One would obtain the same results with the potential $W(r)=\frac{q}{r^{p}}-\frac{p}{r^{q}}$ with $p>q>0$.

### 2.1. The continuum problem

We study in this subsection the continuum problem (6) for the Lennard-Jones potential, with $f \in L^{1}(\Omega)$. The natural variational space is

$$
\begin{equation*}
X_{M}(a)=\left\{u \in W^{1,1}(\Omega), \quad \frac{1}{u^{\prime}} \in L^{12}(\Omega), \quad u^{\prime}>0 \text { a.e., } \quad u(0)=0, \quad u(L)=a\right\} \tag{41}
\end{equation*}
$$

which will possibly need to be enlarged in order for the energy (5) to have a minimizer, as will be seen below. Let us set

$$
\begin{align*}
\theta_{M} & =\int_{\Omega}\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\inf F_{M}-F_{M}(x)\right) \mathrm{d} x,  \tag{42}\\
v_{1}(x) & =\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\inf F_{M}-F_{M}(x)\right), \tag{43}
\end{align*}
$$

where $F_{M}$ is defined by (15). We also recall (see [1,2]) the definition of the set

$$
S B V(\Omega)=\left\{u \in \mathcal{D}^{\prime}(\Omega), \quad u^{\prime}=D_{a} u+\sum_{i \in \mathbb{N}} v_{i} \delta_{x_{i}}, \quad D_{a} u \in L^{1}(\Omega), \quad x_{i} \in \Omega, \quad \sum_{i \in \mathbb{N}}\left|v_{i}\right|<+\infty\right\} .
$$

We now state the main result of the present subsection. Its proof is contained in Appendix A.
Theorem 2.1 (minimizers of the continuum LJ model). If $\theta_{M} \geq a$, where $\theta_{M}$ is defined by (42), then the problem

$$
\begin{equation*}
I_{M}^{1}=\inf \left\{E_{M}(u), u \in X_{M}(a)\right\} \tag{44}
\end{equation*}
$$

where $X_{M}(a)$ is defined by (41) and $E_{M}$ is defined by (5), has a unique minimizer.
If $\theta_{M}<a$, then the problem (44) is not attained, but the problem

$$
\begin{equation*}
I_{M}^{B V}=\inf \left\{E_{M}(u), u \in S B V(\Omega), \frac{1}{u^{\prime}} \in L^{12}(\Omega), u^{\prime}>0, u(0)=0, u(L)=a\right\} \tag{45}
\end{equation*}
$$

has at least one minimizer. Moreover, $I_{M}^{B V}=I_{M}^{1}$ and the minimizers of the problem (45) are the functions

$$
u(x)=\int_{0}^{x} v_{1}(t) \mathrm{d} t+\sum_{i \in \mathbb{I}} \tilde{v}_{i} H\left(x-x_{i}\right)
$$

where $v_{1} \in L^{1}(\Omega)$ is defined by (43), $\mathbb{I}$ is any countable set, and $\tilde{v}_{i}$ and $x_{i}$ are any real numbers such that

$$
\sum_{i \in \mathbb{I}} \tilde{v}_{i}=a-\theta_{M} \quad \text { and } \quad \forall i \in \mathbb{I}, \quad \tilde{v}_{i}>0, x_{i} \in \arg \inf F_{M}
$$

Remark 2.2. Let $u \in S B V(\Omega)$ : its derivative reads $u^{\prime}=D_{a} u+\sum_{i} \tilde{v}_{i} \delta_{x_{i}}$ with $D_{a} u \in L^{1}(\Omega)$. The notation $u^{\prime}>0$ means $D_{a} u>0$ a.e. on $\Omega$ and $\tilde{v}_{i}>0$. When $u^{\prime}>0$, we also use the convention $\frac{1}{u^{\prime}}=\frac{1}{D_{a} u}$. The reason is that the inverse of a regularization of $u^{\prime}$ converges to the inverse of $D_{a} u$ in the sense of distribution. Since $W_{\mathrm{LJ}}(+\infty)=0$, we will also use the convention $W_{\mathrm{LJ}}\left(u^{\prime}\right)=W_{\mathrm{LJ}}\left(D_{a} u\right)$.

### 2.2. The atomistic problem

In this subsection, we study the atomistic problem (2), where the energy $E_{\mu}$ is given by (1) with $W \equiv W_{\mathrm{LJ}}$. In particular, we show that, for some particular choices of boundary conditions, a fracture appears. This means that the distance between a pair (and actually only one) of consecutive atoms is outstretched. The ideas of the proof are first explained on the simple case $f \equiv 0$. Next we deal with the general case, which is more technical. The main result of this subsection is Theorem 2.3, which is a generalization of some results given in [24].

### 2.2.1. The case of no body force

To study problem (2), we need the following lemma.
Lemma 2.1. If $a>L$, there exists $h_{0}$ such that, for all $h \leq h_{0}$, there exists a unique pair $\left(s(h), s_{f}(h)\right) \in \mathbb{R}^{2}$ such that

$$
\begin{equation*}
1 \leq s(h) \leq 1+h, W_{\mathrm{LJ}}^{\prime}(s(h))=W_{\mathrm{LJ}}^{\prime}\left(s_{f}(h)\right) \text { and }(L-h) s(h)+h s_{f}(h)=a . \tag{46}
\end{equation*}
$$

In addition, we have the estimates

$$
s_{f}(h) \sim_{h \rightarrow 0} \frac{a-L}{h} \text { and } s(h)-1 \sim_{h \rightarrow 0} C_{0} h^{7}
$$

for some $C_{0}$ that does not depend on $h$.
We skip the proof of Lemma 2.1, since it proceeds from an elementary study of the variations of the function $g(s)=W_{\mathrm{LJ}}^{\prime}(s)-W_{\mathrm{LJ}}^{\prime}\left(\frac{a-(L-h) s}{h}\right)$.

We now state
Theorem 2.2. We suppose that there are no body force: $f \equiv 0$.
If $a \leq L$, then (2) has a unique minimizer, defined by $u_{\mu}^{i}=i h a / L, i=0, \ldots, N$.
If $a>L$, then there exists $h_{0}$ such that, for all $h \leq h_{0}$, the minimizers of (2) are exactly the $N$ discrete functions defined for $i_{\mu} \in\{0, \ldots, N-1\}$ by

$$
\begin{equation*}
\frac{u_{\mu}^{i_{\mu}+1}-u_{\mu}^{i_{\mu}}}{h}=s_{f}(h) \text { and } \forall i \neq i_{\mu}, \frac{u_{\mu}^{i+1}-u_{\mu}^{i}}{h}=s(h), \tag{47}
\end{equation*}
$$

where $s(h)$ and $s_{f}(h)$ are defined by Lemma 2.1.
The proof is contained in Appendix B.

### 2.2.2. The general case

We now assume that the body forces $f$ are in $\mathcal{C}^{0}(\bar{\Omega})$, and are not necessarily zero. This regularity assumption is needed for $E_{\mu}$ to be well-defined. For any configuration $u \in X_{\mu}(a)$, we define a partition of the set of indices $\{0, \ldots, N-1\}$ in 3 different subsets:

$$
\begin{gathered}
G_{1}(u)=\left\{i \in[0, N-1] ; 0<\frac{u^{i+1}-u^{i}}{h} \leq 1\right\}, \quad G_{2}(u)=\left\{i \in[0, N-1] ; 1<\frac{u^{i+1}-u^{i}}{h}<r_{c}\right\} \\
G_{3}(u)=\left\{i \in[0, N-1] ; r_{c} \leq \frac{u^{i+1}-u^{i}}{h}\right\}
\end{gathered}
$$

Let us set

$$
\begin{align*}
\underline{F_{\mu}} & =\inf _{i=0, \ldots, N-1} F_{\mu}^{i}  \tag{48}\\
\theta_{\mu} & =h \sum_{i=0}^{N-1}\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\underline{F_{\mu}}-F_{\mu}^{i}\right) \tag{49}
\end{align*}
$$

where $F_{\mu}$ is defined by (16). In view of (27), we have $\lim _{h \rightarrow 0} \theta_{\mu}=\theta_{M}$, where $\theta_{M}$, given by (42), is the threshold for appearance of a fracture in the continuum model (see Thm. 2.1). We note that, if $f \equiv 0, \theta_{\mu}=\theta_{M}=L$. To study problem (2), we need the following lemma:
Lemma 2.2 (estimate on the Lagrange multiplier for the atomistic problem (2)). Let $i_{\mu}$ be an index such that $F_{\mu}^{i_{\mu}}=\underline{F_{\mu}}$, and let us assume that $a>\theta_{M}$.

There exists $h_{0}$ such that, for all $h \leq h_{0}$, there exists a unique $\lambda_{\mu}$ such that

$$
\begin{equation*}
0<\lambda_{\mu} \leq h \quad \text { and } \quad h \sum_{i \in\{0, \ldots, N-1\}, i \neq i_{\mu}} \psi\left(\underline{F_{\mu}}-F_{\mu}^{i}+\lambda_{\mu}\right)+h \varphi\left(\lambda_{\mu}\right)=a \tag{50}
\end{equation*}
$$

where $\psi$ and $\varphi$ are defined by (39) and (40).
In addition, $\lambda_{\mu}$ does not depend on $i_{\mu}$ and satisfies $\lambda_{\mu} \sim_{h \rightarrow 0} C_{0} h^{7}$, for some $C_{0}$ that does not depend on $h$.
The proof of Lemma 2.2 is rather simple and based on the study of the variations on $[0, h]$ of the function $g_{\mu}$ defined by $g_{\mu}(\lambda)=\lambda-W_{\mathrm{L} J}^{\prime}\left(\frac{a-h \sum_{i \neq i_{\mu}} \psi\left(\underline{\left.F_{\mu}-F_{\mu}^{i}+\lambda\right)}\right.}{h}\right)$. We now turn to Theorem 2.3 that is the main result of this section. Its proof is contained in Appendix C.
Theorem 2.3 (minimizers of the atomistic problem (2)). We assume that $f \in \mathcal{C}^{0}(\bar{\Omega})$. Let $\theta_{\mu}$ be defined by (49). If $a \leq \theta_{\mu}$, then (2) has a unique minimizer.
If $a>\theta_{M}$, there exists $h_{0}$ such that, for all $h \leq h_{0}$, the minimizers of (2) are exactly the discrete functions defined for $i_{\mu} \in\{0, \ldots, N-1\}$ such that $F_{\mu}^{i_{\mu}}=\underline{F_{\mu}}$ by $u_{\mu}^{0}=0$ and

$$
\begin{equation*}
\frac{u_{\mu}^{i_{\mu}+1}-u_{\mu}^{i_{\mu}}}{h}=\varphi\left(\lambda_{\mu}\right) \quad \text { and } \forall i \neq i_{\mu}, \frac{u_{\mu}^{i+1}-u_{\mu}^{i}}{h}=\psi\left(\underline{F_{\mu}}-F_{\mu}^{i}+\lambda_{\mu}\right) \tag{51}
\end{equation*}
$$

where $\lambda_{\mu}$ is defined by Lemma 2.2 and $\psi$ and $\varphi$ are defined by (39) and (40). In addition, $G_{3}\left(u_{\mu}\right)=\left\{i_{\mu}\right\}$ and

$$
\begin{equation*}
\frac{u_{\mu}^{i_{\mu}+1}-u_{\mu}^{i_{\mu}}}{h} \sim_{h \rightarrow 0} \frac{a-\theta_{M}}{h} \tag{52}
\end{equation*}
$$

Remark 2.3. If $\theta_{\mu}<\theta_{M}$, Theorem 2.3 does not apply to $a \in\left(\theta_{\mu}, \theta_{M}\right]$. Note however that $\lim _{h \rightarrow 0} \theta_{\mu}=\theta_{M}$, thus all boundary conditions $a$ are asymptotically covered.

### 2.3. The natural coupled approach

We study in this subsection the problem (11). We will see that this coupled problem, though natural, has a flaw. In order to illustrate this fact, we restrict ourselves to the case $f \equiv 0$ (see Rem. 2.6 below for the case $f \neq 0$ ). We also assume that

$$
a>L
$$

so that a fracture must appear when minimizing (11). Note that if $a \leq L$, the minimizers of the continuum and atomistic problems are equal and no singularity appears, and it is therefore not interesting to use a coupled method. We assume that $\Omega=(0, L)$ is partitioned into two subsets $\Omega_{M}$ and $\Omega_{\mu}=\Omega \backslash \Omega_{M}$, and that, for

Figure 3. A minimizer of problem (11).
simplicity, $\Omega_{\mu}=(0, K h], \quad \Omega_{M}=(K h, L)$. We will see in Remark 2.4 below that the treatment of the general case follows exactly the same lines. Our aim is to study the minimization problem (11), where the variational space $X_{c}\left(a, \Omega_{M}\right)$ is defined by (9), with $X_{W}\left(\Omega_{M}\right)=S B V\left(\Omega_{M}\right)$, and where the corresponding energy $E_{c}$ is given by (10), with $W \equiv W_{\mathrm{LJ}}$. The key ingredient of the mathematical analysis is the following observation. Let us choose $x_{0} \in \Omega_{M}$ and let us consider the configurations $u_{1} \in X_{c}\left(a, \Omega_{M}\right)$ and $u_{2} \in X_{c}\left(a, \Omega_{M}\right)$ defined by

$$
\begin{array}{ll}
\forall i \in\{0,1, \ldots, K\}, u_{1}^{i}=i h, & \forall x \in \Omega_{M}, u_{1}(x)=x+(a-L) H\left(x-x_{0}\right),  \tag{53}\\
\forall i \in\{1, \ldots, K\}, u_{2}^{i}=i h+(a-L), & \forall x \in \Omega_{M}, u_{2}(x)=x+(a-L)
\end{array}
$$

and $u_{2}^{0}=0$. Within the configuration $u_{1}$ (resp. $u_{2}$ ), a fracture appears in $\Omega_{M}$ (resp. in $\Omega_{\mu}$ ). We have $E_{c}\left(u_{1}\right)=E_{c}\left(F \in \Omega_{M}\right)=L W_{\mathrm{LJ}}(1)$ and $E_{c}\left(u_{2}\right)=E_{c}\left(F \in \Omega_{\mu}\right)=L W_{\mathrm{LJ}}(1)+h+O\left(h^{7}\right)$, so

$$
\begin{equation*}
E_{c}\left(F \in \Omega_{\mu}\right)>E_{c}\left(F \in \Omega_{M}\right) \tag{54}
\end{equation*}
$$

So, if the energy is defined by (10), a fracture costs less energy when it lies in $\Omega_{M}\left(F \in \Omega_{M}\right)$ than when it lies in $\Omega_{\mu}\left(F \in \Omega_{\mu}\right)$. Hence, the fracture of the minimizers of (11) appears in $\Omega_{M}$, as stated by the following lemma.
Lemma 2.3. For $h$ small enough, the minimizers of problem (11) are of the form

$$
\begin{align*}
u^{i} & =i h \quad \forall i \in\{0,1, \ldots, K\}  \tag{55}\\
u(x) & =x+\sum_{i \in \mathbb{I}} \tilde{v}_{i} H\left(x-x_{i}\right), \quad \forall i, x_{i} \in(K h, L), \tilde{v}_{i}>0 \tag{56}
\end{align*}
$$

with $\mathbb{I} \subset \mathbb{N}$ and $\sum_{i \in \mathbb{I}} \tilde{v}_{i}=a-L$.

Proof. Since the minimum of $W_{\mathrm{LJ}}$ is attained at 1 , we have $E_{c}(u) \geq K h W_{\mathrm{LJ}}(1)+(L-K h) W_{\mathrm{LJ}}(1)$, with a strict inequality if for some $i \in\{0,1, \ldots K-1\}, \frac{u^{i+1}-u^{i}}{h} \neq 1$. Moreover, this value is attained when $u$ is of the form (56). Conversely, if $u$ is a minimizer, we necessarily have (55), and the restriction of $u$ to $\Omega_{M}$ is thus a minimizer of

$$
I_{M}^{K h, L}(a-K h)=\inf \left\{\int_{K h}^{L} W_{\mathrm{LJ}}\left(u^{\prime}\right), u \in S B V(K h, L), u^{\prime}>0, \frac{1}{u^{\prime}} \in L^{12}(K h, L), \quad u(K h)=K h, u(L)=a\right\}
$$

Now, Theorem 2.1 implies that a minimizer of this problem satisfies (56).

Remark 2.4. The case of a general set $\Omega_{\mu}$ may be treated likewise. Then, any minimizer of problem (11) satisfies:

$$
\begin{aligned}
u^{i+1}-u^{i} & =h \quad \forall i \text { s.t. } i h \in \Omega_{\mu} \text { and } i h+h \in \Omega_{\mu}, \\
u^{\prime} & =1+\sum_{i \in \mathbb{I}} \tilde{v}_{i} \delta_{x_{i}} \text { in } \Omega_{M}, \quad \forall i, x_{i} \in \Omega_{M}, \quad \tilde{v}_{i}>0, \quad \text { and } \sum_{i \in \mathbb{I}} \tilde{v}_{i}=a-L .
\end{aligned}
$$

The above argument shows that, in the simplest case where we expect a fracture of the material, for any partition of the domain $\Omega$ into a regular domain $\Omega_{M}$ and a singular one $\Omega_{\mu}$, the fracture naturally appears in the regular one.

Hence, if the following algorithm is used to compute an approximation of $u_{\mu}$ : initialize $\Omega_{\mu}$ to $\emptyset$,
(1) solve (11) for $\Omega_{M}=\Omega \backslash \Omega_{\mu}$;
(2) find the set where the solution $u_{c}$ of (11) has a large derivative, enlarge $\Omega_{\mu}$ correspondingly if necessary and go back to 1 ,
then $\Omega_{\mu}$ converges to $\Omega$, because, at each step, the above algorithm computes a solution having a singularity in the set $\Omega_{M}$. The latest iterations are therefore as costly as the determination of the atomistic solution.
Remark 2.5. A way around the above difficulty might be to allow the set $\Omega_{\mu}$ to shrink back if the computed minimizer happens to be regular enough (in some sense) in $\Omega_{\mu}$. However, we have not been able to solve the difficulty with this alternative strategy.

Remark 2.6. The preceding analysis can be carried out in the case of a force $f \neq 0$ satisfying $f \in \mathcal{C}^{0}(\bar{\Omega})$. Let us assume that $a>\theta_{M}$, where $\theta_{M}$ is defined by (42), and that $\inf _{x \in \Omega_{M}} F_{c}(x)=\inf _{i \in \mathbb{N}_{\mu}} F_{c}^{i}$, where $F_{c}$ is defined by (17) and (18). Let $E_{c}\left(F \in \Omega_{M}\right)$ (resp. $E_{c}\left(F \in \Omega_{\mu}\right)$ ) be the energy of a configuration with a fracture in $\Omega_{M}$ (resp. $\Omega_{\mu}$ ). Then the inequality (54) holds.

### 2.4. A modified coupled approach

In this subsection, we propose a way to build a coupled problem that remedies to the difficulties observed in the previous subsection.

We again assume, for the time being, that the partition $\Omega=\Omega_{M} \cup \Omega_{\mu}$ is given. We show in Theorem 2.5 that the modified coupled variational problem (13) is well-posed. In Theorem 2.6, we show that its solution is a converging approximation of the solution to the atomistic problem (2), and in Section 2.5, we will propose a definition of the partition (see Def. 2.1 below).

The variational space we work with is $X_{c}\left(a, \Omega_{M}\right)$ defined by (9) with

$$
X_{W}\left(\Omega_{M}\right)=\left\{u ; u \in W^{1,1}\left(\Omega_{M}\right), \frac{1}{u^{\prime}} \in L^{12}\left(\Omega_{M}\right)\right\} .
$$

As announced in the Introduction, the modified coupled energy is given by

$$
E_{\bmod }(u)=h \sum_{i \in \mathbb{N}_{\mu}} W_{\mathrm{LJ}}\left(\frac{u^{i+1}-u^{i}}{h}\right)-h \sum_{i, i h \in \Omega_{\mu}} u^{i} f(i h)+\int_{\Omega_{M}} W_{\mathrm{LJ}}^{h}\left(u^{\prime}\right)-u f
$$

with

$$
W_{\mathrm{LJ}}^{h}(r)=W_{\mathrm{LJ}}(r)+\sqrt{h} \tau\left(r-r_{0}\right)
$$

Here, $r_{0}$ is any real number in $\left(1, r_{c}\right)$ and the function $\tau$ is a regularization of the function $t \in \mathbb{R} \mapsto t_{+}=\max (0, t)$ (in particular, it does not depend on $h$ ).

The energy $E_{\text {mod }}$ differs from the natural coupled energy $E_{c}$ given by (10) by the use of the energy density $W_{\mathrm{LJ}}^{h}$ instead of $W_{\mathrm{LJ}}$ on the continuum domain $\Omega_{M}$. Let us explain this choice, assuming that there
are no body forces. According to the definition (12), the energy of the fractured configurations (53) reads $E_{\bmod }\left(F \in \Omega_{\mu}\right)=L W_{\mathrm{LJ}}(1)+h+O\left(h^{7}\right)$ and $E_{\bmod }\left(F \in \Omega_{M}\right)=L W_{\mathrm{LJ}}(1)+(a-L) \sqrt{h}$, so

$$
\begin{equation*}
E_{\bmod }\left(F \in \Omega_{\mu}\right)<E_{\bmod }\left(F \in \Omega_{M}\right) \tag{57}
\end{equation*}
$$

If we compare (54) and (57), we see that, with the modified definition of the coupled energy, a fracture costs now less energy when it lies in $\Omega_{\mu}$ than when it lies in $\Omega_{M}$.
Remark 2.7. It is worth emphasizing that the additional term $\sqrt{h} \tau\left(r-r_{0}\right)$ inserted in $W_{\mathrm{LJ}}^{h}$ is by no means the only manner to successfully modify the interaction potential. We only use the fact that $\sqrt{h} \longrightarrow 0$ and $h \ll \sqrt{h}$.

Let us now assume that the solution $u_{\mu}$ of the atomistic problem (2) shows a fracture (on the atom $i_{\mu}$ ), and that we want to use a coupled model to compute an approximation of $u_{\mu}$. At this point, the domain $\Omega_{M}$ is unknown. In order to determine both $\Omega_{M}$ and an approximation of $u_{\mu}$, a possible algorithm is the one already given in the previous subsection, which consists in iterating over two steps, first solve a coupled problem with $\Omega_{M}$ fixed, second modify the partition according to the computed solution. Assume now that, at some moment, a "correct" partition has been found, in the sense that the atom $i_{\mu}$ (where we expect the fracture to take place) belongs to $\Omega_{\mu}$. At that moment, we want the algorithm to stop, because the zone $\Omega_{\mu}$ is satisfactory. Let us consider the minimization problem of the first step of the algorithm. The position of the fracture is such that its energy cost is minimal. If one works with the coupled energy (10), then, as explained in the previous subsection, the fracture is located in $\Omega_{M}$, which is not satisfactory. If one works with the modified coupled energy (12), then, in view of (57), the fracture is located in $\Omega_{\mu}$ and the computed solution is smooth in $\Omega_{M}$, so the partition is not updated and the algorithm stops.

The difference between $E_{c}$ defined by (10) and $E_{\text {mod }}$ defined by (12) is of order $\sqrt{h}$, that is a small quantity (recall that $h$ is the atomic lattice parameter). However, even if it is small, this correction has an influence on the choices of the zones, since it allows for the zone $\Omega_{\mu}$ to contain the fracture.

Before studying the modified coupled problem (13), we study the continuum problem with energy density $W_{\mathrm{LJ}}^{h}$. The following Theorem (which is to be compared with Theorem 2.1) will be needed in the sequel.
Theorem 2.4. Consider the energy $E_{M}^{h}$ defined by

$$
E_{M}^{h}(u)=\int_{\Omega} W_{\mathrm{LJ}}^{h}\left(u^{\prime}(x)\right)-f(x) u(x) \mathrm{d} x
$$

Let us set $\beta^{h}(x) \in\left(0, r_{c}\right)$ such that $W_{\mathrm{LJ}}^{\prime}\left(\beta^{h}(x)\right)=\sqrt{h}+\inf F_{M}-F_{M}(x)$ and $\theta_{M}^{h}=\int_{\Omega} \beta^{h}(x) \mathrm{d} x$.
If $\theta_{M}^{h} \geq a$, then the problem

$$
\begin{equation*}
\inf \left\{E_{M}^{h}(u), \quad u \in W^{1,1}(\Omega), \quad \frac{1}{u^{\prime}} \in L^{12}(\Omega), \quad u^{\prime}>0 \text { a.e., } \quad u(0)=0, \quad u(L)=a\right\} \tag{58}
\end{equation*}
$$

has a unique minimizer which reads $u(x)=\int_{0}^{x} \psi\left(-\lambda+\inf F_{M}-F_{M}(s)\right) \mathrm{d} s$ for some $\lambda \geq-\sqrt{h}$ and where $\psi$ is defined by (39).

If $\theta_{M}^{h}<a$, then (58) is not attained, but the problem

$$
\begin{equation*}
\inf \left\{E_{M}^{h}(u), \quad u \in \operatorname{SBV}(\Omega), \quad \frac{1}{u^{\prime}} \in L^{12}(\Omega), \quad u^{\prime}>0, \quad u(0)=0, \quad u(L)=a\right\} \tag{59}
\end{equation*}
$$

has at least one minimizer.
Moreover, the minimizers of (59) are exactly the functions $u(x)=\int_{0}^{x} \beta^{h}(t) \mathrm{d} t+\sum_{i \in \mathbb{I}} \tilde{v}_{i} H\left(x-x_{i}\right)$, where $\mathbb{I}$ is any countable set, and $\tilde{v}_{i}$ and $x_{i}$ are any real numbers such that

$$
\sum_{i \in \mathbb{I}} \tilde{v}_{i}=a-\theta_{M}^{h} \quad \text { and } \quad \forall i \in \mathbb{I}, \tilde{v}_{i}>0, x_{i} \in \arg \inf F_{M}
$$

We skip the proof of Theorem 2.4, which is an easy adaptation of the proof of Theorem 2.1.
We now study the existence and the uniqueness of solutions of the modified coupled problem (13). Let $F_{c}$ be defined by (17) and (18), and let us set

$$
\underline{F_{c}}=\inf \left(\inf _{\Omega_{M}} F_{c}, \inf _{i \in \mathbb{N}_{\mu}} F_{c}^{i}\right)
$$

The threshold for the appearance of a fracture will be shown to be

$$
\theta_{\mathrm{mod}}=\int_{\Omega_{M}}\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\underline{F_{c}}-F_{c}(x)\right) \mathrm{d} x+h \sum_{i \in \mathbb{N}_{\mu}}\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\underline{F_{c}}-F_{c}^{i}\right) .
$$

Remark 2.8. The modified coupled problem (13) could have been introduced in the convex case, although it was not needed (the coupled problem (11) leads to satisfactory results). In this case, one would have proved results similar to those given in Lemma 1.1 and Theorem 1.1.

To study the problem (13), we need the following lemma:
Lemma 2.4. Let us assume that $a>\theta_{M}$, where $\theta_{M}$ is defined by (42), and that the partition is such that, for any $h$ small enough, there exists $i_{\text {mod }} \in \mathbb{N}_{\mu}$ such that

$$
\begin{equation*}
\underline{F_{c}} \leq F_{c}^{i_{\bmod }} \leq \underline{F_{c}}+C h \tag{60}
\end{equation*}
$$

for some constant $C$ that does not depend on $h$.
Then there exists $h_{0}$ such that, for all $h \leq h_{0}$, there exists a unique $\lambda_{\text {mod }}$ such that $0 \leq \lambda_{\text {mod }} \leq C h$ and

$$
\begin{equation*}
h \sum_{i \in \mathbb{N}_{\mu}, i \neq i_{\bmod }} \psi\left(\underline{F_{c}}-F_{c}^{i}+\lambda_{\bmod }\right)+h \varphi\left(\underline{F_{c}}-F_{c}^{i_{m o d}}+\lambda_{\bmod }\right)+\int_{\Omega_{M}} \psi\left(\underline{F_{c}}-F_{c}(x)+\lambda_{m o d}\right) \mathrm{d} x=a \tag{61}
\end{equation*}
$$

where $\psi$ and $\varphi$ are defined by (39) and (40).
Proof. Let us define $g_{\bmod }(\lambda)=\lambda+\underline{F_{c}}-F_{c}^{i_{\bmod }}-W_{\mathrm{LJ}}^{\prime}\left(\frac{p_{\bmod }(\lambda)}{h}\right)$ on $[0,2 C h]$, where

$$
\left.p_{\bmod }(\lambda)=a-h \sum_{i \in \mathbb{N}_{\mu}, i \neq i_{\bmod }} \psi \underline{\left(F_{c}\right.}-F_{c}^{i}+\lambda\right)-\int_{\Omega_{M}} \psi\left(\underline{F_{c}}-F_{c}(x)+\lambda\right) \mathrm{d} x
$$

For $h$ small enough, $g_{\text {mod }}$ is an increasing function and $g_{\bmod }(2 C h) \geq C h-W_{\mathrm{LJ}}^{\prime}\left(\frac{a-\theta_{M}}{2 h}\right)>0$. Moreover, $g_{\bmod }(0)<0$. Hence there exists a unique $\lambda_{\bmod } \in[0,2 C h]$ such that $g_{\bmod }\left(\lambda_{\bmod }\right)=0$.
Theorem 2.5 (minimizers of the modified coupled problem). We assume that $f \in \mathcal{C}^{0}(\bar{\Omega})$ and that there exists $\varepsilon_{f}>0$ such that (26) is satisfied.

If $a \leq \theta_{\text {mod }}$, then problem (13) has a unique minimizer $u_{\text {mod }}$, which is smooth: there exists $C_{0}$ independent of $h$ such that

$$
\begin{equation*}
\left|u_{m o d}\right|_{W^{1, \infty}\left(X_{c}\right)} \leq C_{0} \tag{62}
\end{equation*}
$$

where $|\cdot|_{W^{1, \infty}\left(X_{c}\right)}$ is defined by (30).
If $a>\theta_{M}$, and if

$$
\begin{equation*}
\exists i_{0} \in \mathbb{N}_{\mu} \text { such that } \underline{F_{\mu}} \leq F_{\mu}^{i_{0}} \leq \underline{F_{\mu}}+C_{1} h, \tag{63}
\end{equation*}
$$

for some constant $C_{1} \geq 0$ independent of $h$ (recall $\underline{F_{\mu}}$ is defined by (48)), then there exists $h_{0}>0$ such that, for all $h \leq h_{0}$, the minimizers of (13) are exactly the functions defined, for $i_{m o d} \in \mathbb{N}_{\mu}$ such that $F_{c}^{i_{\text {mod }}}=\inf _{i \in \mathbb{N}_{\mu}} F_{c}^{i}$,
by $u_{\text {mod }}(0)=0$ and

$$
\left\{\begin{array}{l}
u_{\text {mod }}^{\prime}(x)=\psi\left(\lambda_{\text {mod }}+\underline{F_{c}}-F_{c}(x)\right) \text { on } \Omega_{M},  \tag{64}\\
\frac{u_{\text {mod }}^{i+1}-u_{\text {mod }}^{i}}{h}=\psi\left(\lambda_{\text {mod }}+\underline{F_{c}}-F_{c}^{i}\right) \text { for all } i \in \mathbb{N}_{\mu}, i \neq i_{\text {mod }}, \\
\frac{u_{\text {mod }}^{i_{m o d}+1}-u_{\text {mod }}^{i_{\text {mod }}}}{h}=\varphi\left(\lambda_{\text {mod }}+\underline{F_{c}}-F_{c}^{i_{m o d}}\right),
\end{array}\right.
$$

where $\lambda_{\text {mod }}$ is defined by Lemma 2.4.
Remark 2.9. If $\theta_{\mathrm{mod}}<\theta_{M}$, Theorem 2.5 does not apply to $a \in\left(\theta_{\bmod }, \theta_{M}\right]$. Note however that $\lim _{h \rightarrow 0} \theta_{\mathrm{mod}}=\theta_{M}$, thus all boundary conditions $a$ are asymptotically covered.

Proof of Theorem 2.5. The proof in the case $\theta_{\bmod } \geq a$ follows the same pattern as the proof of Theorem 2.1 (in the case $\left.\theta_{M} \geq a\right)$. We concentrate on the case $a>\theta_{M}$. Let us set

$$
\begin{align*}
& P_{x}^{c}(t)=W_{\mathrm{LJ}}^{h}(t)+\left(F_{c}(x)-\underline{F_{c}}\right) t  \tag{65}\\
& P_{i}^{c}(t)=W_{\mathrm{LJ}}(t)+\left(F_{c}^{i}-\underline{F_{c}}\right) t \tag{66}
\end{align*}
$$

and, for $i \in \mathbb{N}_{\mu}$,

$$
\begin{equation*}
v_{1, c}^{i}=\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\underline{F_{c}}-F_{c}^{i}\right) . \tag{67}
\end{equation*}
$$

For $x \in \Omega_{M}$, we also define $\beta_{x}^{c} \in\left(0, r_{c}\right)$ such that

$$
\begin{equation*}
W_{\mathrm{LJ}}^{\prime}\left(\beta_{x}^{c}\right)=\sqrt{h}+\underline{F_{c}}-F_{c}(x) . \tag{68}
\end{equation*}
$$

We first reformulate the energy $E_{\text {mod }}$, which reads
$E_{\bmod }(u)=\int_{\Omega_{M}} P_{x}^{c}\left(u^{\prime}(x)\right) \mathrm{d} x+h \sum_{i \in \mathbb{N}_{\mu}} P_{i}^{c}\left(\frac{u^{i+1}-u^{i}}{h}\right)+a\left(\underline{F_{c}}-F_{c}(L)\right)$.
Let us consider the problem

$$
\begin{equation*}
\bar{I}_{\mathrm{mod}}=\inf \left\{\bar{E}_{\mathrm{mod}}(v), v \in Y_{c}\left(a, \Omega_{M}\right)\right\}, \tag{69}
\end{equation*}
$$

where $\bar{E}_{\text {mod }}$ is given by

$$
\begin{equation*}
\bar{E}_{\bmod }(v)=\int_{\Omega_{M}} P_{x}^{c}(v(x)) \mathrm{d} x+h \sum_{i \in \mathbb{N}_{\mu}} P_{i}^{c}\left(v^{i}\right) \tag{70}
\end{equation*}
$$

and where $Y_{c}\left(a, \Omega_{M}\right)$ is given by

$$
Y_{c}\left(a, \Omega_{M}\right)=\left\{\begin{array}{c}
v ; v \in L^{1}\left(\Omega_{M}\right), \frac{1}{v} \in L^{12}\left(\Omega_{M}\right), v_{\mid \mathbb{N}_{\mu}} \text { is the discrete set }  \tag{71}\\
\text { of variables }\left(v^{i}\right)_{i \in \mathbb{N}_{\mu}}, v>0, \int_{\Omega_{M}} v+h \sum_{i \in \mathbb{N}_{\mu}} v^{i}=a
\end{array}\right\}
$$

Clearly, $I_{\text {mod }}=\bar{I}_{\text {mod }}+a\left(\underline{F_{c}}-F_{c}(L)\right)$ and $u$ is a minimizer of (13) if and only if $v$, defined by $\forall x \in \Omega_{M}$, $v(x)=u^{\prime}(x)$ and $\forall i \in \mathbb{N}_{\mu}, v^{i}=\frac{u^{i+1}-u^{i}}{h}$, is a minimizer of (69).
Step 1 (a lower bound on the atomistic deformation). Let $u_{n}$ be a minimizing sequence of problem (13) and let $v_{n}$ be the associated minimizing sequence of problem (69). Since $u_{n}$ is an increasing function, we have $0 \leq v_{n}^{i} \leq a / h$ for all $i$ in $\mathbb{N}_{\mu}$. So, up to a subsequence extraction, we can assume that the sequence $\left(v_{n}^{i}\right)_{n}$ converges. Let us set

$$
\begin{equation*}
a_{\mu}^{\infty}=\lim _{n \rightarrow+\infty} h \sum_{i \in \mathbb{N}_{\mu}} v_{n}^{i} \tag{72}
\end{equation*}
$$

As $\int_{\Omega_{M}} v_{n}+h \sum_{i \in \mathbb{N} \mu} v_{n}^{i}=a$, we can also define $a_{M}^{\infty}=\lim _{n \rightarrow+\infty} \int_{\Omega_{M}} v_{n}(x) \mathrm{d} x=a-a_{\mu}^{\infty}$. Let us establish a lower bound on $a_{\mu}^{\infty}$. For all $t>0$, we have

$$
\begin{align*}
P_{x}^{c}(t) & \geq P_{x}^{c}\left(\beta_{x}^{c}\right)+\sqrt{h}\left(t-\beta_{x}^{c}\right)  \tag{73}\\
P_{i}^{c}(t) & \geq P_{i}^{c}\left(v_{1, c}^{i}\right) \tag{74}
\end{align*}
$$

where $P_{x}^{c}, P_{i}^{c}, \beta_{x}^{c}$ and $v_{1, c}$ are defined by (65), (66), (68) and (67). We now consider (70) with $v \equiv v_{n}$. With (73) and (74), we obtain

$$
\begin{equation*}
\bar{I}_{\mathrm{mod}} \geq \int_{\Omega_{M}} P_{x}^{c}\left(\beta_{x}^{c}\right) \mathrm{d} x+\sqrt{h}\left(a_{M}^{\infty}-\int_{\Omega_{M}} \beta_{x}^{c} \mathrm{~d} x\right)+h \sum_{i \in \mathbb{N}_{\mu}} P_{i}^{c}\left(v_{1, c}^{i}\right) \tag{75}
\end{equation*}
$$

Let us now choose $i_{\text {mod }} \in \mathbb{N}_{\mu}$ such that $F_{c}^{i_{\text {mod }}}=\inf _{i \in \mathbb{N}_{\mu}} F_{c}^{i}$. With (63) and (28), we see that

$$
\begin{equation*}
\underline{F_{c}} \leq F_{c}^{i_{\bmod }} \leq \underline{F_{c}}+C h \tag{76}
\end{equation*}
$$

for some constant $C$ that does not depend on $h$. Let us consider the test function $v_{b}$ defined by $v_{b}(x)=\beta_{x}^{c}$ in $\Omega_{M}, v_{b}^{i}=v_{1, c}^{i}$ for all $i \in \mathbb{N}_{\mu}, i \neq i_{\text {mod }}$, and $v_{b}^{i_{\text {mod }}}$ such that $\int_{\Omega_{M}} v_{b}+h \sum_{i \in \mathbb{N}_{\mu}} v_{b}^{i}=a$. By construction, we have

$$
\begin{equation*}
v_{b}^{i_{\bmod }} \sim_{h \rightarrow 0}\left(a-\theta_{M}\right) / h . \tag{77}
\end{equation*}
$$

The function $\beta_{x}^{c}$ is continuous and positive, and $v_{b}^{i}>0$ for all $i \in \mathbb{N}_{\mu}$. So $v_{b}$ is a test function for (69), and we have

$$
\begin{equation*}
\bar{I}_{\mathrm{mod}} \leq \bar{E}_{\bmod }\left(v_{b}\right)=\int_{\Omega_{M}} P_{x}^{c}\left(\beta_{x}^{c}\right) \mathrm{d} x+h \sum_{i \in \mathbb{N}_{\mu}} P_{i}^{c}\left(v_{1, c}^{i}\right)+h P_{i_{\mathrm{mod}}}^{c}\left(v_{b}^{i_{\mathrm{mod}}}\right)-h P_{i_{\mathrm{mod}}}^{c}\left(v_{1, c}^{i_{\mathrm{mod}}}\right) . \tag{78}
\end{equation*}
$$

The last two terms of (78) satisfy

$$
\begin{equation*}
h P_{i_{\mathrm{mod}}}^{c}\left(v_{b}^{i_{\mathrm{mod}}}\right)-h P_{i_{\mathrm{mod}}}^{c}\left(v_{1, c}^{i_{\mathrm{mod}}}\right)=h\left(W_{\mathrm{LJ}}\left(v_{b}^{i_{\mathrm{mod}}}\right)-W_{\mathrm{LJ}}\left(v_{1, c}^{i_{\mathrm{mod}}}\right)\right)+h\left(F_{c}^{i_{\mathrm{mod}}}-\underline{F_{c}}\right)\left(v_{b}^{i_{\mathrm{mod}}}-v_{1, c}^{i_{\mathrm{mod}}}\right) \tag{79}
\end{equation*}
$$

We now bound this quantity. From (67), we have $0<v_{1, c}^{i_{\text {mod }}} \leq 1$, thus $W_{\mathrm{LJ}}\left(v_{1, c}^{i_{\text {mod }}}\right) \geq W_{\mathrm{LJ}}(1)$. With this inequality and (77), we obtain

$$
\begin{equation*}
h\left(W_{\mathrm{LJ}}\left(v_{b}^{i_{\mathrm{mod}}}\right)-W_{\mathrm{LJ}}\left(v_{1, c}^{i_{\mathrm{mod}}}\right)\right) \leq C h \tag{80}
\end{equation*}
$$

for some $C$ that does not depend on $h$. Since $\lim _{h \rightarrow 0} h\left(v_{b}^{i_{\text {mod }}}-v_{1, c}^{i_{\text {mod }}}\right)=a-\theta_{M}$, we infer from (76) that

$$
\begin{equation*}
h\left(F_{c}^{i_{\mathrm{mod}}}-\underline{F_{c}}\right)\left(v_{b}^{i_{\mathrm{mod}}}-v_{1, c}^{i_{\mathrm{mod}}}\right) \leq C h \tag{81}
\end{equation*}
$$

for some $C$ that does not depend on $h$. Collecting (80) and (81), we obtain $h P_{i_{\text {mod }}}^{c}\left(v_{b}^{i_{\text {mod }}}\right)-h P_{i_{\text {mod }}}^{c}\left(v_{1, c}^{i_{\text {mod }}}\right) \leq C h$. Inserting this inequality in (78) and making use of (75), we see that $a_{M}^{\infty}-\int_{\Omega_{M}} \beta_{x}^{c} \mathrm{~d} x \leq C \sqrt{h}$. Since $\theta_{M}=\lim _{h \rightarrow 0}\left(\int_{\Omega_{M}} \beta_{x}^{c} \mathrm{~d} x+\int_{\Omega_{\mu}}\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\inf F_{M}-F_{M}(x)\right) \mathrm{d} x\right)$, we obtain, for $h$ small enough, the following lower bound on $a_{\mu}^{\infty}$ :

$$
\begin{equation*}
\frac{a-\theta_{M}}{2}+\int_{\Omega_{\mu}}\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\inf F_{M}-F_{M}(x)\right) \mathrm{d} x \leq a_{\mu}^{\infty} \tag{82}
\end{equation*}
$$

Step 2 (an auxiliary problem). For any positive real numbers $a_{M}$ and $a_{\mu}$, let us define

$$
\begin{equation*}
I_{M}\left(a_{M}\right)=\inf \left\{\int_{\Omega_{M}} P_{x}^{c}(v(x)) \mathrm{d} x, v \in L^{1}\left(\Omega_{M}\right), \frac{1}{v} \in L^{12}\left(\Omega_{M}\right), v>0 \text { a.e. on } \Omega_{M}, \int_{\Omega_{M}} v=a_{M}\right\} \tag{83}
\end{equation*}
$$

and

$$
\begin{equation*}
I_{\mu}\left(a_{\mu}\right)=\inf \left\{h \sum_{i \in \mathbb{N}_{\mu}} P_{i}^{c}\left(v^{i}\right), v^{i}>0, h \sum_{i \in \mathbb{N}_{\mu}} v^{i}=a_{\mu}\right\} \tag{84}
\end{equation*}
$$

Problem (83) (resp. (84)) can be studied with arguments similar to the ones used to prove Theorem 2.4 (resp. Thm. 2.3). The conclusion is the following: let

$$
\begin{equation*}
a_{M}^{t h}=\int_{\Omega_{M}} \psi\left(\sqrt{h}+\inf _{\Omega_{M}} F_{c}-F_{c}(x)\right) \mathrm{d} x \tag{85}
\end{equation*}
$$

and

$$
\begin{equation*}
a_{\mu}^{t h}=\int_{\Omega_{\mu}}\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\inf _{\Omega} F_{M}-F_{M}(x)\right) \mathrm{d} x . \tag{86}
\end{equation*}
$$

If $a_{M} \leq a_{M}^{t h}$, then problem (83) has a unique minimizer which is continuous, and if $a_{M}>a_{M}^{t h}$, then problem (83) has no minimizer (any minimizing sequence converges to some measure which includes Dirac masses). If $a_{\mu}>a_{\mu}^{t h}$, then a fracture appears in the minimizer(s) of (84).

With (69), (70) and (71), we see that $\bar{I}_{\text {mod }}=\inf \left\{I_{M}(a-\bar{a})+I_{\mu}(\bar{a}), \bar{a} \in[0, a]\right\}$. Let us define $g$ by

$$
\begin{equation*}
g(\bar{a})=I_{M}(a-\bar{a})+I_{\mu}(\bar{a}) \tag{87}
\end{equation*}
$$

and let $\bar{a}^{*}$ be any real number in $[0, a]$ such that $\bar{I}_{\text {mod }}=\inf g=g\left(\bar{a}^{*}\right)$. One can consider a minimizing sequence of problem (84) with $a_{\mu}=\bar{a}^{*}$, and one can also consider a minimizing sequence of problem (83) with $a_{M}=a-\bar{a}^{*}$. So we can build a minimizing sequence $v_{n}$ of problem (69) and apply results of Step 1 to this sequence. By construction, $h \sum_{i \in \mathbb{N}_{\mu}} v_{n}^{i}=\bar{a}^{*}$, so the real number $a_{\mu}^{\infty}$ defined by (72) reads $a_{\mu}^{\infty}=\bar{a}^{*}$. Hence, with (82) and (86), we see that $\bar{a}^{*} \in I_{g}$, where we set $I_{g}=\left[\frac{a-\theta_{M}}{2}+a_{\mu}^{t h}, a\right]$. So $\bar{I}_{\text {mod }}=\inf \left\{g(\bar{a}), \bar{a} \in I_{g}\right\}$. In the sequel of this Step, we study the variations of the function $g$ to show that, on the interval $I_{g}, g$ has a unique minimizer.

Let us choose $\bar{a} \in I_{g}$, let us set $a_{\mu}=\bar{a}$ and $a_{M}=a-\bar{a}$ and let us consider problems (83) and (84). Since $\bar{a}>a_{\mu}^{\text {th }}$, problem (84) is an atomistic problem with boundary conditions so that a fracture appears. With results of Section 2.2, one can show that there exists $\lambda_{\mu} \in[0, h]$ such that the minimizers $v$ of (84) read $v^{i_{\text {mod }}}=\varphi\left(\lambda_{\mu}\right)$ and $\forall i \neq i_{\text {mod }}, v^{i}=\psi\left(\inf _{i \in \mathbb{N}_{\mu}} F_{c}^{i}-F_{c}^{i}+\lambda_{\mu}\right)$, where $i_{\text {mod }}$ is any index such that $F_{c}^{i_{\text {mod }}}=\inf _{i \in \mathbb{N}_{\mu}} F_{c}^{i}$. We have also shown that $\lambda_{\mu}$ depends on $a_{\mu}$ but not on $i_{\text {mod }}$. As a consequence, we can compute $I_{\mu}\left(a_{\mu}\right)$ and show that

$$
\begin{equation*}
\frac{\mathrm{d} I_{\mu}\left(a_{\mu}\right)}{\mathrm{d} a_{\mu}}=\lambda_{\mu}+\inf _{i \in \mathbb{N}_{\mu}} F_{c}^{i}-\underline{F_{c}} . \tag{88}
\end{equation*}
$$

In addition,

$$
\begin{equation*}
\frac{\mathrm{d} \lambda_{\mu}}{\mathrm{d} a_{\mu}} \sim_{h \rightarrow 0}-C h^{7} \tag{89}
\end{equation*}
$$

for some constant $C>0$. We now study problem (83). If $a_{M} \leq a_{M}^{\text {th }}$ defined by (85), then problem (83) has a unique minimizer $v$ which reads $v(x)=\psi\left(-\lambda_{M}+\inf _{\Omega_{M}} F_{c}-F_{c}(x)\right)$ for some $\lambda_{M} \geq-\sqrt{h}$. If $a_{M}>a_{M}^{\text {th }}$, then problem (83) has one or many minimizers $v$ which read $v(x)=\psi\left(\sqrt{h}+\inf _{\Omega_{M}} F_{c}-F_{c}(x)\right)+$ Dirac masses . So we can compute $I_{M}\left(a_{M}\right)$ and show that

$$
\begin{equation*}
\frac{\mathrm{d} I_{M}\left(a_{M}\right)}{\mathrm{d} a_{M}}=-\lambda_{M}+\inf _{\Omega_{M}} F_{c}-\underline{F_{c}}, \tag{90}
\end{equation*}
$$

where $\lambda_{M} \in[-\sqrt{h},+\infty)$. If $a_{M} \geq a_{M}^{t h}$, then $\lambda_{M}=-\sqrt{h}$, and if $a_{M} \leq a_{M}^{t h}$, then

$$
\begin{equation*}
\frac{\mathrm{d} \lambda_{M}}{\mathrm{~d} a_{M}} \leq-\frac{W_{\mathrm{LJ}}^{\prime \prime}(1)}{2\left|\Omega_{M}\right|} \tag{91}
\end{equation*}
$$

We now study the variations of the function $g$ defined by (87). In view of (88) and (90), it satisfies

$$
\begin{equation*}
g^{\prime}(\bar{a})=\lambda_{M}-\inf _{\Omega_{M}} F_{c}+\lambda_{\mu}+\inf _{i \in \mathbb{N}_{\mu}} F_{c}^{i} \tag{92}
\end{equation*}
$$

If $\inf _{i \in \mathbb{N}_{\mu}} F_{c}^{i} \geq \inf _{\Omega_{M}} F_{c}$, then $\underline{F_{c}}=\inf _{\Omega_{M}} F_{c}$, and with (76), we obtain

$$
\begin{equation*}
\inf _{i \in \mathbb{N}_{\mu}} F_{c}^{i}-\inf _{\Omega_{M}} F_{c} \leq C h \tag{93}
\end{equation*}
$$

The above inequality also holds if $\inf _{i \in \mathbb{N}_{\mu}} F_{c}^{i}<\inf _{\Omega_{M}} F_{c}$. Inserting (93) in (92), and since $\lambda_{\mu} \leq h$, we obtain $g^{\prime}(\bar{a}) \leq \lambda_{M}+C h$ for some constant $C$ that does not depend on $h$.

If $a_{M}=a-\bar{a} \geq a_{M}^{t h}$ then $\lambda_{M}=-\sqrt{h}$, so $g^{\prime}(\bar{a})<0$. If $a-\bar{a} \leq a_{M}^{t h}$, we differentiate (92) with respect to $\bar{a}$, and with (89) and (91), one can show that $g^{\prime \prime}(\bar{a})>0$. Since $g^{\prime}(a)=+\infty$, there exists a unique $\bar{a}^{*}$ which minimizes $g$ on $I_{g}$, and $\bar{a}^{*} \in\left(a-a_{M}^{t h}, a\right)$.

Step 3 (conclusion). We know that $\bar{I}_{\text {mod }}=\inf g=g\left(\bar{a}^{*}\right)$ with $\bar{a}^{*} \in I_{g} \cap\left(a-a_{M}^{t h}, a\right)$. There exist minimizers for problem (83) with $a_{M}=a-\bar{a}^{*}<a_{M}^{t h}$ and for problem (84) with $a_{\mu}=\bar{a}^{*}$. So problems (69) and (13) have a minimizer. Let now $u_{\text {mod }}$ be a minimizer of problem (13) and let $v_{\text {mod }}$ be its first derivative, which is a minimizer of (69). As $g$ has a unique minimizer $\bar{a}^{*}$, we see that $\int_{\Omega_{M}} v_{\bmod }(x) \mathrm{d} x=a-\bar{a}^{*}<a_{M}^{t h}$, so that $u_{\text {mod }}$ has no fracture on $\Omega_{M}$. We also see that $h \sum_{i \in \mathbb{N}_{\mu}} v_{\bmod }^{i}=\bar{a}^{*} \geq \frac{a-\theta_{M}}{2}+a_{\mu}^{t h}$, so $u_{\text {mod }}$ has a unique fracture on $\Omega_{\mu}$. We apply Theorem 2.3 on problem (84) and Theorem 2.4 on problem (83), and we obtain (64) for some Lagrange multiplier $\lambda_{\text {mod }}^{*} \in(0, C h)$.

We now identify $\lambda_{\text {mod }}^{*}$. We know that $\lambda_{\text {mod }}^{*} \in(0, C h)$, and we see from (64) that $\lambda_{\text {mod }}^{*}$ satisfies (61). In addition, we see that (63) implies (60). Since $a>\theta_{M}$, we can apply Lemma 2.4, that defines $\lambda_{\text {mod }}$, and we have $\lambda_{\bmod }^{*}=\lambda_{\text {mod }}$.

We now estimate the difference between a minimizer $u_{\text {mod }}$ of the modified coupled problem (13) and a minimizer $u_{\mu}$ of the atomistic problem (2).

Theorem 2.6 (estimate on the minimizers). We assume that $f \in \mathcal{C}^{0}(\bar{\Omega})$ and that there exists $\kappa_{f}>0$ such that (26) is satisfied. Let $u_{\mu}$ be a minimizer of problem (2) and $u_{\text {mod }}$ be a minimizer of problem (13).

If $a<\theta_{M}$, then there exist $h_{0} \leq 1$ and $C\left(\kappa_{f}\right)$, that both depend on $\kappa_{f}$, such that, for all $h \leq h_{0}$, the minimizers $u_{\mu}$ and $u_{\text {mod }}$, as well as their respective energies, are at distance of order $h$ in the sense that

$$
\begin{gather*}
\left|\left(\Pi_{\mu} u_{m o d}\right)-u_{\mu}\right|_{W^{1, \infty}\left(X_{\mu}\right)}+\left|u_{m o d}-\left(\Pi_{c} u_{\mu}\right)\right|_{W^{1, \infty}\left(X_{c}\right)} \leq C\left(\kappa_{f}\right) h \kappa_{f},  \tag{94}\\
\left\|\left(\Pi_{\mu} u_{m o d}\right)-u_{\mu}\right\|_{L^{\infty}\left(X_{\mu}\right)}+\left\|u_{m o d}-\left(\Pi_{c} u_{\mu}\right)\right\|_{L^{\infty}\left(X_{c}\right)} \leq C\left(\kappa_{f}\right) h \kappa_{f}  \tag{95}\\
\left|I_{m o d}-I_{\mu}\right| \leq C\left(\kappa_{f}\right) h \kappa_{f} \tag{96}
\end{gather*}
$$

where $\Pi_{c}$ and $\Pi_{\mu}$ are the operators defined in Definition 1.4, and $\|\cdot\|_{L^{\infty}\left(X_{c}\right)},|\cdot|_{W^{1, \infty}\left(X_{c}\right)},\|\cdot\|_{L^{\infty}\left(X_{\mu}\right)}$ and $|\cdot|_{W^{1, \infty}\left(X_{\mu}\right)}$ are the norms defined by (29), (30) and (31). In addition, the function $\kappa_{f} \mapsto C\left(\kappa_{f}\right)$ is bounded on any compact set.

If $a>\theta_{M}$, and if the partition $\Omega=\Omega_{M} \cup \Omega_{\mu}$ satisfies (63), then there exist $h_{0} \leq 1$ and a constant $C$ (that both depend on $\kappa_{f}$ ) such that, for all $h \leq h_{0}$, there exist $i_{\mu} \in\{0, \ldots, N-1\}$ and $i_{\text {mod }} \in \mathbb{N}_{\mu}$ so that

$$
\begin{gather*}
\left\|u_{\text {mod }}^{\prime}-\left(\Pi_{c} u_{\mu}\right)^{\prime}\right\|_{L^{\infty}\left(\Omega_{M} \backslash\left[i_{\mu} h, i_{\mu} h+h\right]\right)} \leq C h,  \tag{97}\\
\sup _{i \in \mathbb{N}_{\mu}, i \neq i_{\mu}, i \neq i_{\text {mod }}}\left|\frac{u_{\text {mod }}^{i+1}-u_{\text {mod }}^{i}}{h}-\frac{u_{\mu}^{i+1}-u_{\mu}^{i}}{h}\right| \leq C h,  \tag{98}\\
\left|\left(u_{\text {mod }}^{i_{\text {mod }}+1}-u_{\text {mod }}^{i_{\text {mod }}}\right)-\left(u_{\mu}^{i_{\mu}+1}-u_{\mu}^{i_{\mu}}\right)\right| \leq C h,  \tag{99}\\
u_{\text {mod }}^{i_{\text {mod }}+1}-u_{\text {mod }}^{i_{\text {mod }}} \sim_{h \rightarrow 0} a-\theta_{M}, \quad u_{\mu}^{i_{\mu}+1}-u_{\mu}^{i_{\mu}} \sim_{h \rightarrow 0} a-\theta_{M},  \tag{100}\\
\left|I_{\text {mod }}-I_{\mu}\right| \leq C h . \tag{101}
\end{gather*}
$$

In the case $a>\theta_{M}$, we see that both $u_{\mu}$ and $u_{\text {mod }}$ have a singularity, that is localized on a unique atom pair (see (100)). With (99), we can see that the difference between the discontinuity of $u_{\text {mod }}$ and of $u_{\mu}$ converges to 0 when $h$ goes to zero.

Proof. We first treat the case $a<\theta_{M}$. Then, for $h$ small enough, the atomistic problem (2) and the modified coupled problem (13) are well-posed (see Thms. 2.3 and 2.5), and the analysis can be conducted in exactly the same way as in the convex case (see Thm. 1.1). We thus obtain estimates (94), (95) and (96), which are similar to (33), (34), (35), (36) and (37).

We now treat the case $a>\theta_{M}$. Then, for $h$ small enough, the configuration $u_{\mu}$, which is a minimizer of the atomistic problem (2), is given by (51) for some $i_{\mu} \in\{0, \ldots, N-1\}$ and some $\lambda_{\mu} \in(0, h]$ (see Thm. 2.3). The configuration $u_{\text {mod }}$, which is a minimizer of problem (13), is given by (64) for some $i_{\text {mod }} \in \mathbb{N}_{\mu}$ and some $\lambda_{\text {mod }} \in(0, C h]$ (see Thm. 2.5). Hence, we obtain

$$
\begin{equation*}
\left|\lambda_{\mu}-\lambda_{\bmod }\right| \leq C h \tag{102}
\end{equation*}
$$

for some constant $C$ that does not depend on $h$. Collecting (51), (64) and (102), we obtain estimates (97) and (98). Using boundary conditions, one can prove (99). The estimate (52) implies the estimate (100) on $u_{\mu}$, and we infer from the latter and (99) the estimate (100) on $u_{\text {mod }}$. Collecting (97), (98) and (99), we obtain the energy estimate (101).

### 2.5. Definition of the partition

In the statement of Theorem 2.6, we have supposed that we were given some body forces $f$ and a partition $\Omega=\Omega_{M} \cup \Omega_{\mu}$ satisfying (26) and (63). In the sequel, we describe a strategy to find such a partition without resorting to the computation of $F_{\mu}$, an object which is expensive to compute.

Definition 2.1 (partition in the Lennard-Jones case). We assume that $f \in W^{1,1}(\Omega)$. Let us fix $\kappa_{f}>0$, and let $u_{M} \in S B V(\Omega)$ be a minimizer of the continuum problem (45).

The interval $(i h, i h+h)$ is said to be a regular interval if $f$ satisfies

$$
\forall x \in(i h, i h+h),|f(x)| \leq \kappa_{f} \quad \text { and } \quad \int_{i h}^{i h+h}\left|f^{\prime}(x)\right| \mathrm{d} x \leq h \frac{\kappa_{f}}{L}
$$

and if $u_{M}$ is continuous on $[i h, i h+h]$.

We define $\Omega_{M}$ by

$$
\Omega_{M}=\bigcup_{(i h, i h+h)}^{*} \text { regular }(i h, i h+h) \text { and } \Omega_{\mu}=\Omega \backslash \Omega_{M}
$$

where $\bigcup^{*}$ means that the point $\{i h\}$ is also included in $\Omega_{M}$ if both $(i h-h, i h)$ and $(i h, i h+h)$ are regular intervals.

Note that we make a stronger assumption on $f$ than before (until now, we have only assumed $f \in \mathcal{C}^{0}(\bar{\Omega})$ ).
Remark 2.10. In the case $a \leq \theta_{M}$, one can show that problem (45) has a unique minimizer $u_{M}$, which is the minimizer of (44). So $u_{M}$ is continuous on $\Omega$ and the last condition for an interval to be regular is always satisfied.

Theorem 2.7. Let us consider a partition $\Omega=\Omega_{M} \cup \Omega_{\mu}$ as defined by Definition 2.1. Then the body forces $f$ satisfy (26). If $a>\theta_{M}$, then the function $F_{\mu}$ defined by (16) satisfies (63).

Proof. Estimates (26) are a direct consequence of the definition of $\Omega_{M}$. We now assume $a>\theta_{M}$ and prove (63). Let us first note that the assumption $f \in W^{1,1}(\Omega)$ implies that

$$
\begin{equation*}
\forall k \in\{0, \ldots, N\}, \quad\left|F_{M}(k h)-F_{\mu}^{k}\right| \leq h\left\|f^{\prime}\right\|_{L^{1}(\Omega)} \tag{103}
\end{equation*}
$$

which is a better estimate than (27).
Theorem 2.1 shows that the minimizers $u_{M}$ of (45) read $u_{M}(x)=\int_{0}^{x} v_{1}(t) \mathrm{d} t+\sum_{i \in \mathbb{I}} \tilde{v}_{i} H\left(x-x_{i}\right)$, where $v_{1} \in L^{1}(\Omega)$ is defined by (43), $\mathbb{I}$ is any countable set, and $\tilde{v}_{i}$ and $x_{i}$ are such that, for all $i \in \mathbb{I}, \tilde{v}_{i}>0$ and $x_{i} \in \arg \inf F_{M}$. So $u_{M}$ is not continuous at $x_{1}$. Let $\sigma_{1}$ be such that $x_{1} \in\left[\sigma_{1} h, \sigma_{1} h+h\right)$. So the interval $\left(\sigma_{1} h, \sigma_{1} h+h\right)$ is not regular, thus $\left[\sigma_{1} h, \sigma_{1} h+h\right] \subset \Omega_{\mu}$, i.e. $\sigma_{1} \in \mathbb{N}_{\mu}$. With (103), we see that

$$
\begin{equation*}
\left|F_{M}\left(\sigma_{1} h\right)-F_{\mu}^{\sigma_{1}}\right| \leq h\left\|f^{\prime}\right\|_{L^{1}(\Omega)} \tag{104}
\end{equation*}
$$

We also have

$$
\begin{equation*}
\left|F_{M}\left(x_{1}\right)-F_{M}\left(\sigma_{1} h\right)\right| \leq \int_{\sigma_{1} h}^{x_{1}}|f(s)| \mathrm{d} s \leq h\|f\|_{L^{\infty}(\Omega)} \tag{105}
\end{equation*}
$$

We also infer from (103) that

$$
\begin{equation*}
\left|\inf F_{M}-\underline{F_{\mu}}\right| \leq C h \tag{106}
\end{equation*}
$$

for some $C$ that does not depend on $h$, and where $\underline{F_{\mu}}=\inf _{0 \leq i \leq N-1} F_{\mu}^{i}$. As $F_{M}\left(x_{1}\right)=\inf F_{M}$, we infer from (104), (105) and (106) that $\left|F_{\mu}^{\sigma_{1}}-\underline{F_{\mu}}\right| \leq C h$. As $\sigma_{1} \in \mathbb{N}_{\mu}$, we obtain (63).

## Appendix A

Proof of Theorem 2.1. The energy (5) can also be written

$$
\begin{equation*}
E_{M}(u)=\int_{\Omega}\left(W_{\mathrm{LJ}}\left(u^{\prime}(x)\right)+\left(F_{M}(x)-\inf F_{M}\right) u^{\prime}(x)\right) \mathrm{d} x+a\left(\inf F_{M}-F_{M}(L)\right) \tag{107}
\end{equation*}
$$

We first treat the case $\theta_{M} \geq a$. Consider the following minimization problem:

$$
\bar{I}_{M}=\inf \left\{\bar{E}_{M}(v), \quad v \in L^{1}(\Omega), \quad v>0 \text { a.e., } \quad \frac{1}{v} \in L^{12}(\Omega), \quad \int_{\Omega} v=a\right\}
$$

where $\bar{E}_{M}(v)=\int_{\Omega} W_{\mathrm{LJ}}(v)+\left(F_{M}-\inf F_{M}\right) v$. Clearly, $I_{M}^{1}=\bar{I}_{M}+a\left(\inf F_{M}-F_{M}(L)\right)$ and $u$ is a minimizer of $I_{M}^{1}$ if and only if $u^{\prime}$ is a minimizer of $\bar{I}_{M}$. Let us define

$$
\begin{equation*}
v_{0}(x)=\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\inf F_{M}-F_{M}(x)-\lambda\right) \tag{108}
\end{equation*}
$$

where $\lambda \geq 0$ is chosen such that $\int_{\Omega} v_{0}=a$. This is possible because $\int_{\Omega}\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\inf F_{M}-F_{M}(x)\right) \mathrm{d} x=\theta_{M} \geq a$ and $\lim _{\lambda \rightarrow+\infty} \int_{\Omega}\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\inf F_{M}-F_{M}(x)-\lambda\right) \mathrm{d} x=L\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}(-\infty)=0$. We see that $v_{0}(x)$ is a continuous function which satisfies $v_{0}(x) \geq\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\inf F_{M}-\sup F_{M}-\lambda\right)>0$. Thus it is a test function for $\bar{I}_{M}$. Consider now $v \in L^{1}(\Omega)$ satisfying $v>0,1 / v \in L^{12}(\Omega)$ and $\int_{\Omega} v=a$. The function $\underline{v}=\inf \{v, 1\}$ satisfies $\bar{E}_{M}(v) \geq \bar{E}_{M}(\underline{v})$. Define now for $\alpha \in[0,1]$ the function $p(\alpha)=\bar{E}_{M}\left((1-\alpha) v_{0}+\alpha \underline{v}\right)$. We have that $p$ is convex, because both $v_{0}$ and $\underline{v}$ ly in $(0,1]$ where $W_{\text {LJ }}$ is convex, and that $p^{\prime}(0)=-\lambda \int_{\Omega}\left(\underline{v}-v_{0}\right) \geq 0$, hence $p$ is nondecreasing. Therefore $p(0)=\bar{E}_{M}\left(v_{0}\right) \leq p(1)=\bar{E}_{M}(\underline{v}) \leq \bar{E}_{M}(v)$. Hence, $v_{0}$ is a minimizer of $\bar{I}_{M}$. On the other hand, if for some $v$ as above, $\bar{E}_{M}\left(v_{0}\right)=\bar{E}_{M}(v)$, then $p(\alpha)$ must be constant on $\alpha \in[0,1]$ and $\bar{E}_{M}(v)=\bar{E}_{M}(\underline{v})$. As the minimum of $W_{\mathrm{LJ}}$ is attained at 1 , the latter implies that $v=\underline{v}$, while $p$ constant implies that $p^{\prime \prime}=0$, thus $v_{0}=\underline{v}$ (because $W_{\mathrm{LJ}}$ is strictly convex on $(0,1]$ ). This shows that $v_{0}$ is the unique minimizer of $\bar{I}_{M}$, and that $u_{0}(x)=\int_{0}^{x} v_{0}(t) \mathrm{d} t$ is the unique minimizer of (44).

We now turn to the case $\theta_{M}<a$ and show that (45) has at least a minimizer. Consider $u \in S B V(\Omega)$ such that $1 / u^{\prime} \in L^{12}(\Omega), u^{\prime}>0, u(0)=0$ and $u(L)=a$. We use the notation $u^{\prime}=D_{a} u+\sum_{i \in \mathbb{I}} \tilde{v}_{i} \delta_{x_{i}}$ with $D_{a} u \in L^{1}(\Omega), D_{a} u>0$ and $\tilde{v}_{i}>0$. Recall that we use the convention that $W_{\mathrm{LJ}}\left(u^{\prime}\right)=W_{\mathrm{LJ}}\left(D_{a} u\right)$. Thus

$$
\begin{equation*}
E_{M}(u)=\int_{\Omega} P_{x}\left(D_{a} u(x)\right) \mathrm{d} x+\sum_{i \in \mathbb{I}} \tilde{v}_{i}\left(F_{M}\left(x_{i}\right)-\inf F_{M}\right)+a\left(\inf F_{M}-F_{M}(L)\right), \tag{109}
\end{equation*}
$$

where $P_{x}(t)$ is the function

$$
\begin{equation*}
P_{x}(t)=W_{\mathrm{LJ}}(t)+\left(F_{M}(x)-\inf F_{M}\right) t \tag{110}
\end{equation*}
$$

On $(0,+\infty)$, this function has a unique minimizer which is the function $v_{1}(x)$ defined by (43).
So $P_{x}\left(D_{a} u(x)\right) \geq P_{x}\left(v_{1}(x)\right)$ on $\Omega$ and we infer from (109) that

$$
\begin{equation*}
E_{M}(u) \geq \int_{\Omega} P_{x}\left(v_{1}(x)\right) \mathrm{d} x+\sum_{i \in \mathbb{I}} \tilde{v}_{i}\left(F_{M}\left(x_{i}\right)-\inf F_{M}\right)+a\left(\inf F_{M}-F_{M}(L)\right) \tag{111}
\end{equation*}
$$

Consider now a point $x_{0} \in \arg \inf F_{M}$, and define

$$
\begin{equation*}
u_{0}(x)=\int_{0}^{x} v_{1}(t) \mathrm{d} t+\left(a-\theta_{M}\right) H\left(x-x_{0}\right) \tag{112}
\end{equation*}
$$

We have $D_{a} u_{0}=v_{1} \in L^{1}(\Omega)$. Since $v_{1}$ is a continuous function which satisfies $v_{1}(x) \geq \inf v_{1}>0$, we see that $1 / v_{1} \in L^{12}(\Omega)$, thus $u_{0}$ is an admissible function of (45) and, making use of (109) with $u \equiv u_{0}$, we obtain

$$
\begin{equation*}
E_{M}\left(u_{0}\right)=\int_{\Omega} P_{x}\left(v_{1}(x)\right) \mathrm{d} x+a\left(\inf F_{M}-F_{M}(L)\right) \tag{113}
\end{equation*}
$$

Collecting (111) and (113), we obtain

$$
\begin{equation*}
E_{M}(u) \geq E_{M}\left(u_{0}\right)+\sum_{i \in \mathbb{I}} \tilde{v}_{i}\left(F_{M}\left(x_{i}\right)-\inf F_{M}\right) \tag{114}
\end{equation*}
$$

for all test functions $u$ of problem (45) such that $u^{\prime}=D_{a} u+\sum_{i \in \mathbb{I}} \tilde{v}_{i} \delta_{x_{i}}$. Since $\tilde{v}_{i}>0$, we have $E_{M}(u) \geq E_{M}\left(u_{0}\right)$ and the function $u_{0}$ is a minimizer of problem (45).

We now look for all the minimizers of problem (45). Let $u$ be any test function. From (114), we see that $E_{M}(u)>E_{M}\left(u_{0}\right)$ if there exists $i \in \mathbb{I}$ such that $x_{i} \notin \arg \inf F_{M}$ and $\tilde{v}_{i}>0$. In addition, in view of (109) and (113), we infer from $E_{M}(u)=E_{M}\left(u_{0}\right)$ that $\int_{\Omega} P_{x}\left(D_{a} u(x)\right) \mathrm{d} x=\int_{\Omega} P_{x}\left(v_{1}(x)\right) \mathrm{d} x$. As $v_{1}(x)$ is the unique minimizer of $t \in(0,+\infty) \mapsto P_{x}(t)$, we obtain that $v_{1}=D_{a} u$ a.e. on $\Omega$. Hence, any minimizer of (45) may be written $u(x)=\int_{0}^{x}\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\inf F_{M}-F_{M}(t)\right) \mathrm{d} t+\sum_{i \in \mathbb{I}} \tilde{v}_{i} H\left(x-x_{i}\right)$, where $\mathbb{I}$ is any countable set, $x_{i} \in \arg \inf F_{M}$ and $\tilde{v}_{i}>0$ for all $i \in \mathbb{I}$, and $\sum_{i \in \mathbb{I}} \tilde{v}_{i}=a-\theta_{M}$.

Let us now show that $I_{M}^{B V}=I_{M}^{1}$. We already have $I_{M}^{B V} \leq I_{M}^{1}$ and we have shown that $I_{M}^{B V}=E_{M}\left(u_{0}\right)$, where $u_{0}$ is defined by (112). Let $u_{0}^{\varepsilon}$ be a regularization of $u_{0}$ : then $u_{0}^{\varepsilon}$ is a test function for (44) and $I_{M}^{B V}=E_{M}\left(u_{0}\right)=\lim _{\varepsilon \rightarrow 0} E_{M}\left(u_{0}^{\varepsilon}\right) \geq I_{M}^{1}$. Thus $I_{M}^{B V}=I_{M}^{1}$. To prove that problem (44) is not attained, we argue by contradiction. Let us assume that problem (44) is attained and let $\underline{u}$ be a minimizer. With (107), we see that

$$
\begin{equation*}
E_{M}(\underline{u})=\int_{\Omega} P_{x}\left(\underline{u}^{\prime}(x)\right) \mathrm{d} x+a\left(\inf F_{M}-F_{M}(L)\right) \tag{115}
\end{equation*}
$$

where $P_{x}(t)$ is defined by (110). We have $E_{M}(\underline{u})=I_{M}^{1}=I_{M}^{B V}=E_{M}\left(u_{0}\right)$, thus, in view of (113) and (115), we obtain $\int_{\Omega} P_{x}\left(v_{1}(x)\right) \mathrm{d} x=\int_{\Omega} P_{x}\left(\underline{u}^{\prime}(x)\right) \mathrm{d} x$, which implies that $v_{1}(x)=\underline{u}^{\prime}(x)$ a.e. on $\Omega$. But this is impossible since $\int_{\Omega} v_{1}=\theta_{M}<a=\int_{\Omega} \underline{u}^{\prime}$.

## Appendix B

Proof of Theorem 2.2. As we impose the increasing condition $u^{i+1}>u^{i}$, any minimizing sequence $u_{n}^{i}$ satisfies $0 \leq u_{n}^{i} \leq a$ for all $i$, hence is compact in $\mathbb{R}^{N+1}$. Thus, one can extract a subsequence that converges to a configuration (denoted by $u_{\mu}$ ) which is a minimizer of the energy. This configuration satisfies the constraint $u_{\mu}^{i+1}>u_{\mu}^{i}$ for all $i$. Otherwise, there exists $i$ such that $\lim _{n \rightarrow+\infty} u_{n}^{i+1}-u_{n}^{i}=0$, which implies, as $W_{\mathrm{LJ}}(0)=+\infty$, that the infimum (2) is $+\infty$, which is a contradiction. Hence, (2) has at least one minimizer.

Choosing $u^{i}=i h a / L$ as a test function, we show that $L W_{\mathrm{LJ}}(a / L) \geq I_{\mu}$. Bounding $W_{\mathrm{LJ}}$ from below by $W_{\mathrm{LJ}}^{* *}$, and utilizing the convexity of $W_{\mathrm{LJ}}^{* *}$, we show that $I_{\mu} \geq L W_{\mathrm{LJ}}^{* *}(a / L)$. Thus $L W_{\mathrm{LJ}}\left(\frac{a}{L}\right) \geq I_{\mu} \geq L W_{\mathrm{LJ}}^{* *}\left(\frac{a}{L}\right)$.

We first treat the case $a \leq L$, where $W_{\mathrm{LJ}}(a / L)=W_{\mathrm{LJ}}^{* *}(a / L)$, thus $I_{\mu}=L W_{\mathrm{LJ}}(a / L)$. The configuration $u_{\mu}^{i}=i h a / L$ is thus a minimizer. Let us now consider a configuration $u$ for which the quantities $\frac{u^{i+1}-u^{i}}{h}, i=0, \ldots, N-1$, are not all equal to $a / L$. Then

$$
E_{\mu}(u)=h \sum_{i=0}^{N-1} W_{\mathrm{LJ}}\left(\frac{u^{i+1}-u^{i}}{h}\right) \geq h \sum_{i=0}^{N-1} W_{\mathrm{LJ}}^{* *}\left(\frac{u^{i+1}-u^{i}}{h}\right)>L W_{\mathrm{LJ}}^{* *}\left(\frac{h}{L} \sum_{i=0}^{N-1} \frac{u^{i+1}-u^{i}}{h}\right)
$$

where we have made use of the strict case of the convexity inequality. Thus we have $E_{\mu}(u)>L W_{\mathrm{LJ}}^{* *}(a / L)=I_{\mu}$, and $u$ is not a minimizer. This shows the uniqueness claimed in the theorem.

We now turn to the case $a>L$. Let us consider a minimizer $u_{\mu}$ of problem (2). As $W_{\mathrm{LJ}}(0)=+\infty$, the constraint $u^{i+1}>u^{i}$ is not active, so the Euler-Lagrange equation of (2) reads as (23):

$$
\forall i \in\{1, \ldots, N-1\}, \quad W_{\mathrm{LJ}}^{\prime}\left(\frac{u_{\mu}^{i}-u_{\mu}^{i-1}}{h}\right)=W_{\mathrm{LJ}}^{\prime}\left(\frac{u_{\mu}^{i+1}-u_{\mu}^{i}}{h}\right)
$$

If one slope $\frac{u_{\mu}^{i+1}-u_{\mu}^{i}}{h}$ is equal to or smaller than 1 , then the same holds for the other slopes, and this is in contradiction with the fact that $a>L$. So all the slopes are strictly larger than 1. In addition, due to the variations of $W_{\mathrm{LJ}}$, there are two values $s^{*}(h)$ and $s_{f}^{*}(h)$, with $1<s^{*}(h) \leq r_{c} \leq s_{f}^{*}(h), W_{\mathrm{LJ}}^{\prime}\left(s^{*}(h)\right)=W_{\mathrm{LJ}}^{\prime}\left(s_{f}^{*}(h)\right)$, such that each of the slopes is either $s^{*}(h)$ or $s_{f}^{*}(h)$. Let $k=\operatorname{Card}\left\{i \in\{0, \ldots, N-1\}\right.$ such that $\left.\frac{u_{\mu}^{i+1}-u_{\mu}^{i}}{h}=s_{f}^{*}(h)\right\}$. We have $(L-k h) s^{*}(h)+k h s_{f}^{*}(h)=a$ and $I_{\mu}=(L-k h) W_{\mathrm{LJ}}\left(s^{*}(h)\right)+k h W_{\mathrm{LJ}}\left(s_{f}^{*}(h)\right)$.

We claim that $k=1$. For this purpose, we consider the discrete function $u_{b}$ defined by $u_{b}^{i}=i h$ for $i=0, \ldots, N-1$, and $u_{b}^{N}=a$. Its energy is $E_{\mu}\left(u_{b}\right)=(L-h) W_{\mathrm{LJ}}(1)+h W_{\mathrm{LJ}}\left(\frac{a-L}{h}+1\right)$, and satisfies $\lim _{h \rightarrow 0} E_{\mu}\left(u_{b}\right)=L W_{\mathrm{LJ}}(1)$. We first show that $k \neq 0$. Otherwise, all slopes $\left(u_{\mu}^{i+1}-u_{\mu}^{i}\right) / h$ are equal to the same value $s^{*}(h)$, which thus needs to be $a / L$. As $u_{\mu}$ is a minimizer, $I_{\mu}=L W_{\mathrm{LJ}}(a / L)$. However, we also have $I_{\mu} \leq E_{\mu}\left(u_{b}\right)$. Letting $h$ go to zero, we obtain $W_{\mathrm{LJ}}(a / L) \leq W_{\mathrm{LJ}}(1)$, which is a contradiction as $a>L$.

We now show that $k \leq 1$. As $I_{\mu} \leq E_{\mu}\left(u_{b}\right)$, one obtains

$$
\begin{equation*}
L\left(W_{\mathrm{LJ}}\left(s^{*}(h)\right)-W_{\mathrm{LJ}}(1)\right)+k h\left(W_{\mathrm{LJ}}\left(s_{f}^{*}(h)\right)-W_{\mathrm{LJ}}\left(s^{*}(h)\right)\right) \leq-h W_{\mathrm{LJ}}(1) \tag{116}
\end{equation*}
$$

The left hand side is a sum of two nonnegative terms, for $1<s^{*}(h) \leq s_{f}^{*}(h)$ and $W_{\mathrm{LJ}}$ is an increasing function on $[1,+\infty)$. So we have $\lim _{h \rightarrow 0} W_{\mathrm{LJ}}\left(s^{*}(h)\right)=W_{\mathrm{LJ}}(1)$, hence $\lim _{h \rightarrow 0} s^{*}(h)=1$, which in turn implies that $\lim _{h \rightarrow 0} s_{f}^{*}(h)=+\infty$. Inserting this information in (116), we obtain $k \leq 3 / 2$, thus $k=1$ for $h$ small enough.

We finally identify $\left(s^{*}(h), s_{f}^{*}(h)\right)$ for $h$ small enough. We have $(L-h) s^{*}(h)+h s_{f}^{*}(h)=a$. So, using $\lim _{h \rightarrow 0} s^{*}(h)=1$, we see that $s_{f}^{*}(h) \sim_{h \rightarrow 0}(a-L) / h$. So $W_{\mathrm{LJ}}^{\prime}\left(s^{*}(h)\right)=W_{\mathrm{LJ}}^{\prime}\left(s_{f}^{*}(h)\right) \sim C h^{7}$, and $s^{*}(h)=1+O\left(h^{7}\right)$. As a consequence, $s^{*}(h) \in[1,1+h]$. By uniqueness of the pair $\left(s(h), s_{f}(h)\right)$ satisfying (46) (see Lemma 2.1 above), one has $s^{*}(h)=s(h)$ and $s_{f}^{*}(h)=s_{f}(h)$. So $u_{\mu}$ satisfies (47) for some integer $i_{\mu}$.

## Appendix C

Proof of Theorem 2.3. If $f \equiv 0$, then Theorem 2.3 is identical to Theorem 2.2. We now concentrate on the case $f \neq 0$. As in the proof of Theorem 2.1 (Appendix A), we first reformulate the energy, here in term of the slopes

$$
\begin{equation*}
v^{i}=\frac{u^{i+1}-u^{i}}{h}, \quad 0 \leq i \leq N-1 \tag{117}
\end{equation*}
$$

The energy (1) can be written $E_{\mu}(u)=a\left(\underline{F_{\mu}}-F_{\mu}^{N}\right)+h \sum_{i=0}^{N-1}\left(W_{\mathrm{LJ}}\left(\frac{u^{i+1}-u^{i}}{h}\right)+\left(F_{\mu}^{i}-\underline{F_{\mu}}\right) \frac{u^{i+1}-u^{i}}{h}\right)$. Then we consider

$$
\begin{equation*}
\bar{I}_{\mu}=\inf \left\{\bar{E}_{\mu}(v) ; v \in Y_{\mu}(a)\right\}, \tag{118}
\end{equation*}
$$

where the space $Y_{\mu}(a)$ is defined by $Y_{\mu}(a)=\left\{v=\left(v^{0}, \ldots, v^{N-1}\right) \in \mathbb{R}^{N}, h \sum_{i=0}^{N-1} v^{i}=a, v^{i}>0\right\}$, and the energy $\bar{E}_{\mu}$ by $\bar{E}_{\mu}(v)=h \sum_{i=0}^{N-1}\left(W_{\mathrm{LJ}}\left(v^{i}\right)+\left(F_{\mu}^{i}-\underline{F_{\mu}}\right) v^{i}\right)$. Clearly, $I_{\mu}=\bar{I}_{\mu}+a\left(\underline{F_{\mu}}-F_{\mu}^{N}\right)$. If $u$ is a minimizer of (2), then the discrete function $v$ defined from $u$ by (117) is a minimizer of (118). On the other hand, if $v$ is a minimizer of (118), then $u$ defined by $u^{i}=h \sum_{j=0}^{i-1} v^{j}$ for $i \geq 1$ and $u^{0}=0$ is a minimizer of (2).

Let $v_{n}$ be a minimizing sequence of $\bar{I}_{\mu}$. Since $0<v_{n}^{i} \leq a / h$ for all $0 \leq i \leq N-1$ and all $n$, one can extract a subsequence that converges to the configuration $v_{\mu}$. Again, since $W_{\mathrm{LJ}}(0)=+\infty$ and the infimum (118) is not equal to $+\infty$, we have $v_{\mu}^{i}>0$ for all $0 \leq i \leq N-1$ and $v_{\mu}$ is a minimizer of (118). Hence (118), and therefore (2), have at least one minimizer, we denote by $v_{\mu}$ and $u_{\mu}$ two corresponding minimizers of (118) and (2).

In the case $a \leq \theta_{\mu}$, the proof of uniqueness follows the same lines as the proof of Theorem 2.1, in the case $a \leq \theta_{M}$.

We now turn to the case $a>\theta_{M}$. As $\lim _{h \rightarrow 0} \theta_{\mu}=\theta_{M}$, we choose $h$ small enough such that $a>\theta_{\mu}$. We introduce the function $P_{i}(t)=W_{\mathrm{LJ}}(t)+\left(F_{\mu}^{i}-\underline{F_{\mu}}\right) t$, which attains its minimum with respect to $t \in[0,+\infty)$ at $t=v_{1}^{i}$ defined by

$$
\begin{equation*}
v_{1}^{i}=\left(W_{\mathrm{LJ}}^{\prime}\right)^{-1}\left(\underline{F_{\mu}}-F_{\mu}^{i}\right), \quad i=0, \ldots, N-1 \tag{119}
\end{equation*}
$$

We notice that

$$
\begin{equation*}
\forall v \in Y_{\mu}(a), \quad \bar{E}_{\mu}(v)=h \sum_{i=0}^{N-1} P_{i}\left(v^{i}\right) \geq \bar{E}_{\mu}\left(v_{1}\right) \tag{120}
\end{equation*}
$$

As $W_{\mathrm{LJ}}(0)=+\infty$, the constraint $v^{i}>0$ is not active in (118), so the Euler-Lagrange equation of (118) reads

$$
\begin{equation*}
W_{\mathrm{LJ}}^{\prime}\left(v_{\mu}^{i}\right)+F_{\mu}^{i}-\underline{F_{\mu}}=\lambda_{\mu}^{*} \tag{121}
\end{equation*}
$$

where $\lambda_{\mu}^{*}$ is the Lagrange multiplier associated to the constraint $h \sum_{i=0}^{N-1} v_{\mu}^{i}=a$. Since $a>\theta_{\mu}$, one can show that $\lambda_{\mu}^{*}>0$ (otherwise, (121) leads to $v_{\mu}^{i} \leq v_{1}^{i}$, and summing these inequalities leads to $a \leq \theta_{\mu}$ ). It holds that

$$
\begin{equation*}
\forall i \in G_{1}\left(u_{\mu}\right) \cup G_{2}\left(u_{\mu}\right), \quad v_{\mu}^{i}=\psi\left(\underline{F_{\mu}}-F_{\mu}^{i}+\lambda_{\mu}^{*}\right) . \tag{122}
\end{equation*}
$$

Step 1 (liminf $\left.h \operatorname{Card}\left(G_{1}\left(u_{\mu}\right)\right)>0\right)$. In view of (120), we have

$$
\begin{equation*}
\bar{E}_{\mu}\left(v_{1}\right) \leq \bar{I}_{\mu} \tag{123}
\end{equation*}
$$

Let $i_{0}$ be an index such that $F_{\mu}^{i_{0}}=\underline{F_{\mu}}$, and let us consider the function $v_{b}$ defined by $v_{b}^{i}=v_{1}^{i}>0$ for $i \neq i_{0}$ and $v_{b}^{i_{0}}$ such that $h \sum_{i=0}^{N-1} v_{b}^{i}=a$. By construction, $v_{1}^{i_{0}}=1$ and $h v_{b}^{i_{0}}=a-\theta_{\mu}+h$, so

$$
\begin{equation*}
v_{b}^{i_{0}} \sim_{h \rightarrow 0} \frac{a-\theta_{M}}{h}>0 \tag{124}
\end{equation*}
$$

Hence, $v_{b}$ is a test function for (118) and we have $\bar{I}_{\mu} \leq \bar{E}_{\mu}\left(v_{b}\right)$. Collecting this inequality with (123), we have

$$
\begin{equation*}
\bar{E}_{\mu}\left(v_{1}\right) \leq \bar{I}_{\mu} \leq \bar{E}_{\mu}\left(v_{b}\right) \tag{125}
\end{equation*}
$$

Since $F_{\mu}^{i_{0}}=\underline{F_{\mu}}$, we have $\bar{E}_{\mu}\left(v_{b}\right)-\bar{E}_{\mu}\left(v_{1}\right)=h\left(W_{\mathrm{LJ}}\left(v_{b}^{i_{0}}\right)-W_{\mathrm{LJ}}\left(v_{1}^{i_{0}}\right)\right)$. We know that $v_{1}^{i_{0}}=1$. With (124), we obtain

$$
\begin{equation*}
0 \leq \bar{E}_{\mu}\left(v_{b}\right)-\bar{E}_{\mu}\left(v_{1}\right) \leq-h W_{\mathrm{LJ}}(1) \tag{126}
\end{equation*}
$$

With (125) and (126), we have

$$
\begin{equation*}
\lim _{h \rightarrow 0} \bar{I}_{\mu}=\lim _{h \rightarrow 0} \bar{E}_{\mu}\left(v_{1}\right)=\int_{\Omega} W_{\mathrm{LJ}}\left(v_{1}(x)\right)+\left(F_{M}(x)-\inf F_{M}\right) v_{1}(x) \mathrm{d} x \tag{127}
\end{equation*}
$$

where $v_{1}(x)$ is defined by (43). We now prove a lower bound for $\bar{I}_{\mu}$. Since $\bar{I}_{\mu}=h \sum_{i=0}^{N-1}\left(W_{\mathrm{LJ}}\left(v_{\mu}^{i}\right)+\left(F_{\mu}^{i}-\underline{F_{\mu}}\right) v_{\mu}^{i}\right)$, we have $\bar{I}_{\mu} \geq h \sum_{i=0}^{N-1}\left(W_{\mathrm{LJ}}(1)+\left(F_{\mu}^{i}-\underline{F_{\mu}}\right)\right)+h \sum_{i \in G_{1}\left(u_{\mu}\right)}\left(F_{\mu}^{i}-\underline{F_{\mu}}\right)\left(v_{\mu}^{i}-1\right)$. The previous inequality implies $\bar{I}_{\mu}-h \sum_{i=0}^{N-1}\left(W_{\mathrm{LJ}}(1)+\left(F_{\mu}^{i}-\underline{F_{\mu}}\right)\right) \geq-h \operatorname{Card}\left(G_{1}\left(u_{\mu}\right)\right)\left(\sup _{0 \leq i \leq N-1} F_{\mu}^{i}-\underline{F_{\mu}}\right)$. Letting $h$ go to zero in the above inequality, we obtain, in view of (127),

$$
\int_{\Omega} W_{\mathrm{LJ}}\left(v_{1}\right)+\left(F_{M}-\inf F_{M}\right) v_{1}-\int_{\Omega} W_{\mathrm{LJ}}(1)+\left(F_{M}-\inf F_{M}\right) \geq-\liminf _{h \rightarrow 0}\left(h \operatorname{Card}\left(G_{1}\left(u_{\mu}\right)\right)\left(\sup _{0 \leq i \leq N-1} F_{\mu}^{i}-\underline{F_{\mu}}\right)\right)
$$

Since $f \neq 0$, we see that $v_{1}(x) \neq 1$ somewhere in $\Omega$. As $v_{1}(x)$ minimizes the function $W_{\mathrm{LJ}}(t)+\left(F_{M}(x)-\inf F_{M}\right) t$ on $[0,+\infty)$, we obtain $\liminf h \operatorname{Card}\left(G_{1}\left(u_{\mu}\right)\right)>0$, and there exists $L_{1}>0$ such that, for $h$ small enough, $h \operatorname{Card}\left(G_{1}\left(u_{\mu}\right)\right) \geq L_{1}$.

Step 2 (a first estimate of the Lagrange multiplier $\lambda_{\mu}^{*}$ and of $v_{\mu}$ ). In view of (125) and (126), we have $0 \leq \bar{I}_{\mu}-\bar{E}_{\mu}\left(v_{1}\right) \leq-h W_{\mathrm{LJ}}(1)$. Since $\bar{E}_{\mu}(v)=h \sum_{i=0}^{N-1} P_{i}\left(v^{i}\right)$ for any $v \in Y_{\mu}(a)$ (see (120)), we have

$$
\begin{equation*}
h \sum_{i \in G_{1}\left(u_{\mu}\right)}\left(P_{i}\left(v_{\mu}^{i}\right)-P_{i}\left(v_{1}^{i}\right)\right)+h \sum_{i \notin G_{1}\left(u_{\mu}\right)}\left(P_{i}\left(v_{\mu}^{i}\right)-P_{i}\left(v_{1}^{i}\right)\right) \leq-h W_{\mathrm{LJ}}(1) . \tag{128}
\end{equation*}
$$

Since $t \mapsto P_{i}(t)$ attains its minimum at $v_{1}^{i}$, we see that the left hand side of the above inequality is a sum of two nonnegative terms. We know that $v_{1}^{i} \leq 1$. Using the convexity of $P_{i}$ on $(0,1]$, one obtains

$$
\begin{equation*}
\forall i \in G_{1}\left(u_{\mu}\right), \quad P_{i}\left(v_{\mu}^{i}\right)-P_{i}\left(v_{1}^{i}\right) \geq C\left(v_{\mu}^{i}-v_{1}^{i}\right)^{2} \tag{129}
\end{equation*}
$$

where $C$ stands (here and below) for a generic constant which does not depend on $h$. With (119) and (122),
we obtain $v_{\mu}^{i}-v_{1}^{i} \geq C \lambda_{\mu}^{*}$ for some constant $C$. Inserting this information in (128) and (129), one obtains $\left(\lambda_{\mu}^{*}\right)^{2} h \operatorname{Card}\left(G_{1}\left(u_{\mu}\right)\right) \leq O(h)$. As $h \operatorname{Card}\left(G_{1}\left(u_{\mu}\right)\right) \geq L_{1}>0$, we have

$$
\begin{equation*}
0<\lambda_{\mu}^{*} \leq C \sqrt{h} \tag{130}
\end{equation*}
$$

Collecting (119), (122) and (130), we infer that there exists a constant $C$ independent of $h$ such that, for all $i$ in $G_{1}\left(u_{\mu}\right) \cup G_{2}\left(u_{\mu}\right)$, we have $\left|v_{\mu}^{i}-v_{1}^{i}\right| \leq C \lambda_{\mu}^{*}$, so

$$
\begin{gather*}
\forall i \in G_{1}\left(u_{\mu}\right) \cup G_{2}\left(u_{\mu}\right),\left|v_{\mu}^{i}-v_{1}^{i}\right| \leq C \sqrt{h} \\
\forall i \in G_{3}\left(u_{\mu}\right), \quad v_{\mu}^{i} \geq \frac{C}{h^{1 / 14}} \tag{131}
\end{gather*}
$$

Step 3 ( $\left.\operatorname{Card} G_{3}\left(u_{\mu}\right)=1\right)$. For any $i \in G_{1}\left(u_{\mu}\right) \cup G_{2}\left(u_{\mu}\right)$, we see that $v_{1}^{i}$ and $v_{\mu}^{i}$ belong to the interval $(0,1+C \sqrt{h}]$, on which $W_{\mathrm{LJ}}$ and $P_{i}$ are convex. So inequality (129) is valid for all $i \in G_{1}\left(u_{\mu}\right) \cup G_{2}\left(u_{\mu}\right)$, i.e. for all $i \notin G_{3}\left(u_{\mu}\right)$. Thus, (128) implies on the one hand

$$
\begin{equation*}
C h \sum_{i \notin G_{3}\left(u_{\mu}\right)}\left(v_{\mu}^{i}-v_{1}^{i}\right)^{2} \leq h \sum_{i \notin G_{3}\left(u_{\mu}\right)}\left(P_{i}\left(v_{\mu}^{i}\right)-P_{i}\left(v_{1}^{i}\right)\right) \leq-h W_{\mathrm{LJ}}(1) . \tag{132}
\end{equation*}
$$

On the other hand, for any $i \in G_{3}\left(u_{\mu}\right), P_{i}\left(v_{1}^{i}\right) \leq P_{i}(1)=W_{\mathrm{LJ}}(1)+F_{\mu}^{i}-\underline{F_{\mu}}$ and, with (131),

$$
P_{i}\left(v_{\mu}^{i}\right) \geq W_{\mathrm{LJ}}\left(v_{\mu}^{i}\right)+F_{\mu}^{i}-\underline{F_{\mu}} \geq W_{\mathrm{LJ}}\left(\frac{C}{h^{1 / 14}}\right)+F_{\mu}^{i}-\underline{F_{\mu}}
$$

This and (128) gives Card $G_{3}\left(u_{\mu}\right)\left(W_{\mathrm{LJ}}\left(\frac{C}{h^{1 / 14}}\right)-W_{\mathrm{LJ}}(1)\right) \leq \sum_{i \in G_{3}\left(u_{\mu}\right)}\left(P_{i}\left(v_{\mu}^{i}\right)-P_{i}\left(v_{1}^{i}\right)\right) \leq-W_{\mathrm{LJ}}(1)$. So, for $h$ small enough, Card $G_{3}\left(u_{\mu}\right) \leq 1$. If $G_{3}\left(u_{\mu}\right)=\emptyset$, then, with (132), we obtain

$$
0<a-\theta_{\mu}=h \sum_{i=0}^{N-1} v_{\mu}^{i}-v_{1}^{i} \leq \sqrt{L} \sqrt{h \sum_{i=0}^{N-1}\left(v_{\mu}^{i}-v_{1}^{i}\right)^{2}} \leq O(\sqrt{h})
$$

and we come to a contradiction with $a>\theta_{M}=\lim _{h \rightarrow 0} \theta_{\mu}$. So $\operatorname{Card} G_{3}\left(u_{\mu}\right)=1$, and we denote by $i_{\mu}$ its unique index: $G_{3}\left(u_{\mu}\right)=\left\{i_{\mu}\right\}$.

If $F_{\mu}^{i_{\mu}}>\underline{F_{\mu}}$, let $i_{0}$ be an index such that $F_{\mu}^{i_{0}}=\underline{F_{\mu}}$. By exchanging $v_{\mu}^{i_{\mu}}$ and $v_{\mu}^{i_{0}}$, one can lower the energy of $v_{\mu}$. This is in contradiction with the fact that $v_{\mu}$ is minimizer. So $F_{\mu}^{i_{\mu}}=\underline{F_{\mu}}$.

Step 4 (identification of the Lagrange multiplier). We have:
$a-\theta_{M}=a-\theta_{\mu}+o(1)=o(1)+h \sum_{i \notin G_{3}\left(u_{\mu}\right)}\left(v_{\mu}^{i}-v_{1}^{i}\right)+h\left(v_{\mu}^{i_{\mu}}-v_{1}^{i_{\mu}}\right)$.
With (131), we see that $h \sum_{i \notin G_{3}\left(u_{\mu}\right)}\left(v_{\mu}^{i}-v_{1}^{i}\right)=o(1)$. With (119), we have $v_{1}^{i_{\mu}}=1$, so $a-\theta_{M}=o(1)+h v_{\mu}^{i_{\mu}}$. Hence, $v_{\mu}^{i_{\mu}} \sim_{h \rightarrow 0} \frac{a-\theta_{M}}{h}$, which implies (52). As a consequence, $W_{\mathrm{LJ}}^{\prime}\left(v_{\mu}^{i_{\mu}}\right) \sim C h^{7}$. From (121), we obtain $\lambda_{\mu}^{*}=W_{\mathrm{LJ}}^{\prime}\left(v_{\mu}^{i_{\mu}}\right)$. So, for $h$ small enough, we have $\lambda_{\mu}^{*} \in(0, h]$ and, since $h \sum v_{\mu}^{i}=a$, the Lagrange multiplier $\lambda_{\mu}^{*}$ satisfies (50). Since $\lambda_{\mu}$, defined by Lemma 2.2, is the unique solution of (50), we have $\lambda_{\mu}^{*}=\lambda_{\mu}$. Collecting this equality with (121), we obtain (51).
