# ONE-DIMENSIONAL GENERAL FOREST FIRE PROCESSES 

Xavier Bressaud, Nicolas Fournier

#### Abstract

We consider the one-dimensional generalized forest fire process: at each site of $\mathbb{Z}$, seeds and matches fall according to i.i.d. stationary renewal processes. When a seed falls on an empty site, a tree grows immediately. When a match falls on an occupied site, a fire starts and destroys immediately the corresponding connected component of occupied sites. Under some quite reasonable assumptions on the renewal processes, we show that when matches become less and less frequent, the process converges, with a correct normalization, to a limit forest fire model. According to the nature of the renewal processes governing seeds, there are four possible limit forest fire models. The four limit processes can be perfectly simulated. This study generalizes consequently previous results of [15] where seeds and matches were assumed to fall according to Poisson processes.

## Résumé (Processus de feux de forêt généraux en dimension 1)

Nous étudions le processus des feux de forêt généralisé en dimension 1 : sur chaque site de $\mathbb{Z}$, des graines et des allumettes tombent suivant des processus de renouvellement stationnaires i.i.d. Quand une graine tombe sur un site vide, un arbre pousse immédiatement. Quand une allumette tombe sur un site occupé, un feu démarre et brûle immédiatement la composante connexe occupée autour de ce site. Nous montrons - sous des hypothèses raisonnables sur les processus de renouvellement - que lorsque la fréquence des allumettes tend vers zéro, le processus converge, correctement renormalisé, vers un processus limite. Suivant la nature des processus de renouvellement gouvernant l'apparition des graines, quatre processus limites sont possibles. Les quatre modèles limites peuvent être simulés parfaitement. Cette étude généralise des résultats de [15], où nous supposions que graines et allumettes tombaient suivant des processus de Poisson.

## CHAPTER 1

## INTRODUCTION

### 1.1. Introduction

Consider a graph $G=(S, A), S$ being the set of vertices and $A$ the set of edges. Introduce the space of configurations $E=\{0,1\}^{S}$. For $\eta \in E$, we say that $\eta(i)=0$ if the site $i \in S$ is vacant and $\eta(i)=1$ if $i$ is occupied by a tree. Two sites are neighbors if there is an edge between them. We call forests the connected components of occupied sites. For $i \in S$ and $\eta \in E$, we denote by $C(\eta, i)$ the forest around $i$ in the configuration $\eta$ (with $C(\eta, i)=\varnothing$ if $\eta(i)=0$ ). We consider the following (vague) rules:
$\triangleright$ vacant sites become occupied (a seed falls and a tree immediately grows) at rate 1;
$\triangleright$ occupied sites take fire (a match falls) at rate $\lambda>0$;
$\triangleright$ fires propagate to neighbors (inside the forest) at rate $\pi>0$.
Such a model was introduced by Henley [37] and Drossel and Schwabl [27] as a toy model for forest fire propagation and as an example of a simple model intended to clarify the concept of self-organized criticality.

The order of magnitude of the rate of growth is much smaller than the propagation rate, $\pi \gg 1$. We will focus here on the limit case where the propagation is instantaneous: when a tree takes fire, the whole forest (to which it belongs) is destroyed immediately. The model is thus:
$\triangleright$ vacant sites become occupied (a seed falls and a tree immediately grows) at rate 1;
$\triangleright$ matches fall on occupied sites at rate $\lambda$ and then burn instantaneously the corresponding forest.

The features of the model depend on the geometry of the graph; we only consider in this paper the case $S=\mathbb{Z}$ (with its natural set of edges). They also depend on the laws of the processes governing seeds and matches; the standard case is when these
are Poisson processes so that the forest fire process is Markov. We deal here with the most general (stationary) case; Poisson processes are replaced by stationary renewal processes.

Our main preoccupation is the behavior of this model in the asymptotic of rare seeds, namely when $\lambda \rightarrow 0$. We present four possible limit processes (depending on the tail properties of the law of the stationary processes governing seeds) arising when we suitably rescale space and accelerate time while letting $\lambda \rightarrow 0$. This is a considerable generalization of the results obtained in [15].

This introduction consists of six subsections.
(i) In subsection 1.1.1, we briefly recall the concept of self-organized criticality and recall a certain number of models supposed to enjoy self-organized critical properties.
(ii) We present in subsection 1.1.2 a quick history of the forest-fire process, its other possible interpretations and its links with other models.
(iii) subsection 1.1.3 explains the importance of the geometry of the underlying graph $G$ and the links of the forest-fire model with percolation.
(iv) In subsection 1.1.4, we recall what has been done for the (Markov) forest-fire process on $\mathbb{Z}$ from a rigorous mathematical point of view.
(v) subsection 1.1.5 is devoted to a brief exposition of the main ideas of the present paper.
(vi) Finally, we give the plan of the paper in subsection 1.1.6.
1.1.1. Self-organized criticality. - One of the successes of statistical mechanics is to explain how local interactions generate macroscopic effects through simple models on lattices. Among the most striking phenomena are those observed around so-called critical values of the parameters of such models, such as scale-free patterns, power laws, conformal invariance, critical exponents or universality.
1.1.1.1. Paradigm. - The study of self-organized critical systems has become rather popular in physics since the end of the 80 's. These are simple models supposed to clarify temporal and spatial randomness observed in a variety of natural phenomena showing long range correlations, like sand piles, avalanches, earthquakes, stock market crashes, forest fires, shapes of mountains, clouds, etc. It is remarkable that such phenomena reminiscent of critical behavior arise so frequently in nature where nobody is here to finely tune the parameters to critical values.

An idea proposed in 1987 by Bak-Tang-Wiesenfeld [5] to tackle this contradiction is, roughly, that of systems growing toward a critical state and relaxing through catastrophic events: avalanches, crashes, fires, etc. If the catastrophic events become more and more probable when approaching the critical state, the system spontaneously reaches an equilibrium close to the critical state. This idea was developed in [5] through the study of the archetypical sand pile model.

This paradigm was used to investigate various phenomena, from physics to sociology through biology, epidemiology or economics. The pertinence of the conclusions are not always convincing. Discussion to decide if whether or not there is self-organized criticality in nature or in one or another model, or even to decide what self-organized criticality should exactly be, is beyond our purpose. Anyhow let us summarize the usual features of these models:
$\triangleright$ local dynamics but with possibly very long range effects (at high speed) through a simple mechanism;
$\triangleright$ macroscopic states with scaling invariance properties, a priori related to the critical state of a well-known system;
$\triangleright$ long range spatial correlations and power laws for natural observables at fixed times;
$\triangleright$ presence of $1 / f$ or $1 / f^{\alpha}$-noise in the temporal fluctuations of natural observables. We are not experts on this topic, but it seems to be one of the main motivation of self-organized critical systems. It is the subject of the original article of Bak-Tang-Wiesenfield [5] and of considerably many physical papers.

One of the specificities of these models is that the interaction is formally non local; it is local in general, but may, when close to the critical region - whatever this means - have long range effects. This, together with a lack of monotonicity, yields mathematical difficulties that justify a careful treatment.

To understand, explain or illustrate these phenomena, a multitude of models have been proposed to explore various mechanisms that would produce these effects. Simple models, non necessarily realistic, are nice for they try to catch the underlying mechanisms. They have often been treated numerically, in the spirit of Bak-TangWiesenfield [5]. Forest fire models are among them and still need a mathematical rigorous study. Sand pile models, while somehow more complicated, have been more studied.
1.1.1.2. Sand pile models. - Let us explain in a few words what a sand pile model is. First, we assume that we have a definition of what a stable sand pile is. Sand grains fall at random on sites. When a grain falls, if the new pile is unstable, it is immediately re-organized to become stable, through (possibly many) successive elementary steps. Such events are called avalanches. This model was introduced by Bak-TangWiesenfeld [5] and studied by Dhar [25]. Since, there has been a huge amount of results and we will not try to be exhaustive; for surveys see for instance Holroyd-Levine-Meszaros-Peres-Propp-Wilson [39], Goles-Latapy-Magnien-Morvan-Phan [34] or Redig [56].

Let us give a slightly more precise description of the so-called Abelian sand pile model. The state of the system is described by $\eta \in \mathbb{Z}^{S}$, representing local slopes of the sand pile. For instance, when $S=\mathbb{Z}$, think that $\eta(i)=h(i+1)-h(i)$ where $h(i)$ is
the height of the sand pile on the site $i$. A dynamic is defined on $\mathbb{Z}^{S}$ using a matrix $\Delta$ indexed by $S \times S$, called toppling matrix. It has positive entries on the diagonal (think of $\Delta_{i, i}=\gamma$ constant), negative entries when $i, j \in S$ are neighbors and null entries elsewhere. It is dissipative if $\Delta_{i, i}+\sum_{j \neq i} \Delta_{i, j}<0$. Then define the toppling of a site $i$ as the mapping $T_{i}: \mathbb{Z}^{S} \rightarrow \mathbb{Z}^{S}$ defined by

$$
\begin{aligned}
T_{i}(\eta)(j) & =\eta(j)-\Delta_{i, j}, \quad \forall j \in S \text { if } \eta(i)>\Delta_{i, i} ; \\
T_{i}(\eta) & =\eta \text { otherwise } .
\end{aligned}
$$

Toppling at $i$ consists, whenever the slope is too big at $i$, of spreading grains on neighboring sites (possibly in a non conservative way). A pile is stable if for all $i \in S$, $\eta(i) \leq \Delta_{i, i}$ (then, no toppling has any effect). Observe that successive topplings at different sites commute (which explains the term Abelian).

Now consider the situation where sand grains fall at random, on each site, at rate 1. Each time a grain falls, immediately topple (possibly many times) until stability is reached. Some dissipativity assumptions guarantee that this is always possible.

At first glance, arrival of a new sand grain on a site has only a local effect: a non trivial toppling at $i$ may occur. But there can be a chain reaction creating an avalanche. And indeed, the action may, in general, have a long range effect.

These systems have a nice underlying group structure that depends on the size and geometry of the underlying lattice, see e.g. Le Borgne-Rossin [13] for such an algebraic point of view. The thermodynamic limits of the sand-pile models have been investigated. In particular, existence and uniqueness of a stationary measure have been proved. See for instance Maes-Redig-Saada [47] when $S=\mathbb{Z}$ and Járai [42] when $S=\mathbb{Z}^{d}$. Some features of self-organized criticality have been observed for $d>1$, at least numerically, in the physical literature, see e.g. Lübeck-Usadel [46]. For instance, they have studied the sizes of avalanches (number of topplings necessary to stabilize after a grain has been added). A scaling limit was obtained recently by Dürre [31].
1.1.1.3. Other models. - The Abelian sand pile seems to be the most popular sand pile model. However it has a lot of variants: Zhang sand pile model (see Zhang [65], Pietronero-Tartaglia-Zhang [51]), Oslo model (see Christensen-Corral-Frette-FederJossang [20], Amaral-Lauristsen [4]), Oslo rice pile model (see Brylawski [18]), chip firing game (see Tardos [62]), etc.

Moreover, various different models have been introduced and studied with the eyes of self-organized criticality. There is of course the forest fire model that we are going to discuss in this paper. Let us mention briefly some other models: rotor-router model (introduced by Priezzhev-Dhar-Dhar-Krishnamurthy [52] under the name Eulerian walkers model), loop-erased random walks (Majumdar [48]), diffusion/aggregation models (Cafiero-Pietronero-Vespignani [19]), Scheidegger's model of river basin
(Scheidegger [57]), models describing earthquakes (Olami-Feder-Christensen [50]) or crashes in stock markets (Staufer-Sornette $[\mathbf{6 1}, 59]$ ), etc.

As we already mentioned those systems have often been subjected to numerical experimentations and studies. Of course this is a difficult task and it has sometimes been misleading: long range effects need huge simulations, the interpretation of which is not always meaningful.

For surveys on self-organized criticality, see Bak-Tang-Wiesenfeld [6], Dhar [26], Jensen [43] and the references therein.
1.1.2. Forest fire models. - Here we consider the classical forest fire model on $G=(S, A)$. Recall that on each site of $S$, seeds are falling at rate 1 and matches are falling at rate $\lambda$, according to some Poisson processes. A seed falling on a vacant site makes it immediately occupied, and a match falling on an occupied site makes instantaneously vacant the whole corresponding occupied connected component. Thus the forest fire process is Markov (at least if one is able to prove that it exists and is unique).
1.1.2.1. History and numerical studies. - The forest fire model was introduced independently by Henley [37] and Drossel-Schwabl [27]. In the literature, it is generally referred to as the Drossel-Schwabl forest fire model. In their original paper, they consider the case where $S$ is a cube in $\mathbb{Z}^{d}$. They are interested in scaling laws and critical exponents for this model. Orders of magnitude of relevant quantities are derived by analytical computations using essentially mean field considerations. The results are confirmed by computer simulations. In Drossel-Clar-Schwabl [28], the asymptotic behavior of the density of vacant sites in the limit $\lambda \rightarrow 0$ is obtained when $S=\mathbb{Z}$ (using heuristic arguments, see subsubsection 1.1.4.3 below). After this work, numerous numerical or semi-analytical studies have been produced. Among others, let us mention Henecker-Peschel [40] and Pruessner-Jensen [53]. Numerical studies were handled again by Grassberger [35], who computes, when $S=\mathbb{Z}^{2}$, the density of occupied sites, the fractal dimension of fires and the distribution of the fire sizes, in the limit $\lambda \rightarrow 0$.

The first rigorous probabilistic treatment of this model is the paper by van den Berg and Járai [9]. They give a rigorous description of the asymptotic density of vacant sites in the limit $\lambda \rightarrow 0$ for the forest fire process on $\mathbb{Z}$. To our knowledge, all the rigorous results about the forest fire process concern the case where seeds and matches fall according to Poisson processes. See Dürre $[\mathbf{2 9}],[\mathbf{3 0}],[\mathbf{3 1}]$ (existence and uniqueness of the process on $\mathbb{Z}^{d}$ with $\lambda>0$ fixed), van den Berg-Brouwer [7] (behavior of the process near the critical time in dimension 2, as $\lambda \rightarrow 0$ ) and Brouwer-Pennanen [17] (estimates on the cluster size distribution in the asymptotic $\lambda \rightarrow 0$, in dimension 1). See also the papers by the authors $[\mathbf{1 4}]$ (study of the invariant distribution when $\lambda=1$ in dimension 1) and [15] (scaling limit of the one dimensional forest fire process in
the asymptotic $\lambda \rightarrow 0$ ). We will discuss all these results more specifically in this introduction.
1.1.2.2. Real forest fires. - Real forest fires in nature are also a subject of preoccupation and of study from different point of views. In particular there are various statistical studies of sizes (and sometimes shapes) of real forest fires in different regions (see for instance Holmes-Hugget-Westerling [38]). One of the recurrent observations is that the distributions of those fires have heavy tails (power laws) and pleasant scale invariance properties. Another one is the tentative description of the (fractal) geometry of fires (see for instance Mangiavillano [49]). For references, connection with real life and practical interest of these studies, see Cui-Perera [23]. A few studies relate the dynamics of real fires in a given region with theoretical models. One natural task was to compare real data and numerical experiments done with the toy models we have. On this aspect, let us mention the recent (and encouraging) works by Zinck-Grimm-Johst $[\mathbf{6 6}],[67]$. Other studies focus on the propagation of the fire itself, but this is not our main preoccupation here since we have assumed that the propagation is instantaneous.

A direction of study suggested by works on real forest fires is to consider fires in inhomogeneous, for instance random, media. To our knowledge, this aspect has not yet been investigated. Another one, that we address here, is to consider the non Markov case: seeds and matches may not (and actually should not) fall according to Poisson processes.
1.1.2.3. Other interpretations and variations. - The forest fire model has a very simple (and natural) dynamic. It may accept a variety of interpretations. And various modifications can make it fit the description of other phenomena. Indeed, we initially thought of it as a simplification of the avalanche process: snow flakes fall on each site, a snow flake falling on a vacant site makes it occupied, and a snow flake falling on an occupied site makes vacant the whole connected component of occupied sites (such an event being called avalanche). This is nothing but the forest fire process with $\lambda=1$, see $[\mathbf{1 4}]$. More generally, the forest fire process may be used to model phenomena involving geometric relations and a common behavior on connected components; natural examples arise e.g. in epidemiology (change fire by virus). From these points of view, some natural modifications could be explored such as making the growth process have effect only on sites which are neighbors of occupied sites (in the spirit of the so-called contact process). Such variants should be dominated by the standard contact process and by the forest fire process and may enjoy interesting features.

In a different spirit, a directed version of the forest fire model has been studied as a toy model for neural networks. Roughly, the idea is to think of growth as activation and of fire as signal emission. The signal is transmitted along the (directed) connected
component which is at the same time deactivated. The difference is that the underlying graph is a directed graph (usually a tree) and that the signal is (instantaneously) sent according to the directed edge (instead of all the connected component). Let us mention the work of van den Berg-Brouwer [7], which include remarks about this model, and the work of van den Berg-Tóth [10].
1.1.2.4. Coagulation/Fragmentation. - A slight change of point of view about the forest fire model makes explicit a parallel with a class of coagulation/fragmentation processes. Assume e.g. that $S=\mathbb{Z}$. Say that each edge $(i, i+1)$ has mass 1 , and that two neighbor edges $(i-1, i)$ and $(i, i+1)$ are connected (or belong to the same particle) if $\eta(i)=1$. Then each time a seed falls on a vacant site, this glues two particles (preserving the total mass). And each time a match falls on a site (say, belonging to a forest containing $k \geq 1$ sites), this breaks a particle of mass $k+1$ into $k+1$ particles with mass 1 .

We used this remark in [14] to study the evolution of the sizes of particles when neglecting correlation, using a deterministic coagulation-fragmentation equation. Of course, similar considerations can be handled on any graph $G$.
1.1.2.5. Recent results for related models in dimension 1. - Let us mention two recent results about one-dimensional forest fire processes with a somehow different flavor.

Volkov [64] considers a version of the forest fire process on $\mathbb{N}$ where ignition occurs only at 0 . He studies the weak limit of the distribution of the (suitably normalized) delay between to fires involving $n$, as $n \rightarrow \infty$.

Bertoin [12] considers a modified version of Knuth's parking model where random fires burn connected components of cars. On a circle of size $n$, cars arrive at each site at rate 1 . When a car arrives, it occupies the first vacant site (turning clockwise). Molotov cocktails fall on each site at rate $n^{-\alpha}$ where $0<\alpha<1$ is fixed. Bertoin studies the asymptotic behavior of the saturation time as $n \rightarrow \infty$ and observes a phase transition at $\alpha=\frac{2}{3}$.
1.1.2.6. Specific difficulties. - As we already mentioned, one of the difficulties with forest fire models (and with self-organized critical systems in general) is that the interaction is not local. The process, whenever it is Markov, is not Feller and some classical results fail. In dimension one, this difficulty does not yield real problems for the questions of existence and uniqueness of the process. This is essentially due to the fact that obviously, the sizes of the forests always remain finite (even when $\lambda$ is very small). This difficulty is more important in higher dimensions, because in the absence of fires, clusters would become infinite in finite time (due to the fact that in dimension $d \geq 2$, percolation occurs). Fires prevent us from the existence of infinite clusters. But these arbitrarily huge clusters burning make difficult the control of the range of interactions. This difficulty also makes the usual proof of existence of
stationary measures using compactness arguments fail (because indeed there is a lack of continuity).

The lack of monotonicity of these models, although not fundamental, makes the use of standard intuitions and techniques impossible. Monotonicity allows one to compare the processes started from two different ordered initial configurations (coupled in a suitable way). Monotonicity cannot hold here, because a configuration with more trees will burn sooner.
1.1.3. Geometry of the lattice. - The geometry of the underlying lattice is crucial in statistical mechanics. Recall for instance that phase transition for the Ising model on $\mathbb{Z}^{d}$ appears only for $d \geq 2$ (see Velenik [63]). For the forest fire models, the influence of the geometry clearly comes through the behavior of the lattice with respect to percolation. This geometrical influence was already striking in numerical studies. See Grimmett [36] for a very complete book on percolation.
1.1.3.1. Growth without fires/Percolation. - Consider a graph $G=(S, A)$. For all $0 \leq p \leq 1$ consider an i.i.d. family $\{\eta(i), i \in S\}$ of Bernoulli random variables with parameter $p$ (a percolation trial with probability $p$ ). It is well known that there is $0 \leq p_{c} \leq 1$, depending on the graph, such that for all $p<p_{c}$, there are a.s. no infinite connected components of occupied sites, while for $p>p_{c}$, there is at least one infinite connected component with probability 1 . The real number $p_{c}$ is called percolation threshold of $G$. It is rather natural to consider (dynamical) percolation processes on $G$, that are couplings of percolation trials for all $0 \leq p \leq 1$. For instance, consider a family $\left\{T_{i}, i \in S\right\}$ of i.i.d. random variables on $\mathbb{R}_{+}$with exponential distribution with parameter 1. Put $\eta_{t}(i)=0$ if $t<T_{i}$ and $\eta_{t}(i)=1$ if $t \geq T_{i}$. Then for all $t>0,\left\{\eta_{t}(i), i \in S\right\}$ is a percolation trial with probability $P\left(T_{i} \leq t\right)=1-\mathrm{e}^{-t}$. Thus an infinite cluster appears at time $t_{c}$ defined by $1-\mathrm{e}^{-t_{c}}=p_{c}$.

It clearly appears that the percolation threshold plays a crucial role in understanding the behavior of the forest fire process on a given lattice. The simple observation is that the growth process, i.e. without fires $(\lambda=0)$, is exactly a percolation process on the lattice. For $\lambda$ small, and a fortiori for $\lambda \rightarrow 0$ its study is a necessary preliminary. For instance, one aspect is the formation of infinite clusters (although in general those clusters will never appear since, taking fires into account, they must burn before they become infinite). Recall that the percolation threshold is 1 in dimension 1. It is $0<p_{c}^{(d)}<1$ on $\mathbb{Z}^{d}$ and once there is an infinite cluster, there is a unique one. While, for instance on a $d$-regular tree, just after the percolation threshold, there are infinitely many infinite clusters: these situations are rather different and should yield different behaviors for the corresponding forest fire processes. Observe that though, for all $\lambda>0$, the forest fire process is easy to define for small times, things turn out to be more complicated when we reach the critical time $t_{c}$. Even in dimension 1
the separate study of the percolation process makes sense as we shall see further, subsection 1.1.4.4.
1.1.3.2. Modified percolation models. - It has also been fruitful to study modified (for instance dynamical) versions of percolation processes. Models like frozen percolation (Aldous [3], see also Brouwer [16]), invasion-percolation (see for instance Damron-Sapozhnikov-Vágvölgyi [24]), or self-destructive percolation (see van den Berg-Brouwer [7] and more recently van den Berg-Brouwer-Vágvölgyi [8]) are closely related to the forest fire processes. Let us focus one moment on this last example since it has direct implications on forest fire processes.

A typical configuration for the self-destructive percolation model on $\mathbb{Z}^{2}$ with parameter $(p, \delta)$ is generated in three steps: first generate a configuration for the ordinary percolation model with parameter $p$. Next, make all sites in the infinite occupied cluster vacant. Finally, make occupied each vacant site with probability $\delta$. Let $\theta(p, \delta)$ be the probability that 0 belongs, in the final configuration, to an infinite occupied cluster. In a recent paper [8], van den Berg, Brouwer and Vágvölgyi prove that this function is continuous outside of a set of the form $\left\{\left(p_{c}, \delta\right): \delta<\delta_{0}\right\}$. It is conjectured that this function has a discontinuity, roughly meaning that there is $\delta>0$ such that for any $p>p_{c}$, the model with parameter $(p, \delta)$ is sub-critical (there a.s. is no infinite cluster).

In $[\mathbf{7}]$, van den Berg and Brouwer have proved that assumption of a strongly related conjecture yields a result for a 2-dimensional forest fire process after the critical time: there is $t>t_{c}$ such that for all $m \geq 1$,

$$
\liminf _{\lambda \rightarrow 0} \liminf _{n \rightarrow \infty} \operatorname{Pr}\left[\begin{array}{l}
\text { a tree in } \llbracket-m, m \rrbracket^{2} \text { burns before } t \\
\text { in the forest fire process on } S_{n}=\llbracket-n, n \rrbracket^{2}
\end{array}\right] \leq \frac{1}{2} .
$$

1.1.3.3. Thermodynamic limit. - The forest-fire process on a finite graph is a finite state space continuous time Markov chain (if matches and seeds fall according to Poisson processes). Existence and uniqueness of the process thus come for free. Existence of an invariant measure as well. A basic argument also yields uniqueness of the invariant measure (because the configuration with all sites vacant is recurrent). Hence interesting phenomena may arise only when we let the size of the lattice tend to infinity.

When $S=\mathbb{Z}$, it is not very expensive to go directly to the limit: the process is naturally uniquely defined on $\mathbb{Z}$. This is easily seen through a graphical construction of the process (see [15]), see also Proposition 2.1.4 below.

In dimension $d>1$ the situation is more delicate. On $\mathbb{Z}^{d}$ (and actually on any graph with bounded vertex degree) existence has been proved recently by Dürre [29]. He also proved uniqueness, but in two steps: firstly, in [30], he shows that, for $\lambda>0$ large enough (the bound is related to the percolation threshold), the forest-fire process is unique. Only very recently the same author, in [31], tackled the same question on
a graph with bounded vertex degree and for all $\lambda>0$. This is a much more subtle task. To prove this result he has to introduce the so-called blur processes, to show that the influence of matches falling far away from 0 is negligible.
1.1.3.4. Mean field model. - The mean field case is slightly different. Indeed, one has to adopt the dual point of view (on edges). Furthermore, the process cannot be defined directly on an infinite lattice since we consider the complete graph. The point of view developed by Ráth and Tóth in [55] is based on the Erdös-Rényi construction [32]. For all $n \geq 1$, let $S_{n}$ be a set (of vertices) with $\left|S_{n}\right|=n$, and consider the complete graph $G_{n}=\left(S_{n}, A_{n}\right)$. Start initially with all edges vacant. Then edges appear independently at rate $1 / n$. Matches fall at rate $\lambda_{n}$ on each site and destroy instantaneously the whole corresponding occupied connected component. We consider the asymptotic $n \rightarrow \infty$. The various regimes (see Ráth-Tóth [55]) are quite illuminating.
(I) If $\lambda_{n} \ll 1 / n$, then fires are (asymptotically) negligible. Thus we have the same asymptotics as in the Erdös-Réyni model: a giant component appears after some time $T_{\text {gel }}$ (the critical time in this formalism).
(II) If $\lambda_{n} \simeq \lambda / n$, then a giant component appears, but is destroyed after some time. Only the giant component may burn: there are no matches enough to burn finite size forests.
(III) If $1 / n \ll \lambda_{n} \ll 1$, there are not enough fires to burn finite size forests, but too many to let any infinite forest appear. Hence no giant component appears.
(IV) If $\lambda_{n} \simeq \lambda$, then matches may kill finite forests, so that of course, no giant component emerges.
To formalize these statements rigorously, Ráth-Tóth [55] consider the cluster size distributions: $\nu_{n, k}(t)$ is the number of vertices belonging to a connected component of size $k$ at time $t$ divided by $n$. Consider also the concentrations $c_{n, k}(t):=\nu_{n, k}(t) / k$. As $n \rightarrow \infty$, the limit concentrations $\left(c_{k}(t)\right)_{k \geq 1}$ should satisfy a system of differential equations closely related to Smoluchowski's coagulation equations with multiplicative kernel and mono-disperse initial condition:

$$
\begin{aligned}
& c_{1}(0)=1, \quad c_{k}(0)=0, \quad k \geq 2, \\
& \frac{\mathrm{~d}}{\mathrm{~d} t} c_{k}(t)=\frac{1}{2} \sum_{i=1}^{k-1} i(k-i) c_{i}(t) c_{k-i}(t)-k c_{k}(t) \sum_{i=1}^{\infty} i c_{i}(t), \quad k \geq 1 .
\end{aligned}
$$

Such equations, discussed in details in Aldous [2], have been introduced by Smoluchowski [58] in 1916. These equations are subjected to a phase transition known as gelation: some mass is lost at some positive finite instant $T_{\text {gel }}$, due to the emergence of a giant particle. For $t>T_{\text {gel }}$, we have to decide what to do with the giant particle. It can e.g. interact with finite particles (Flory's equation) or be removed from the system (Smoluchowski's equation). See Aldous [1] and [33] for such considerations.

In the regime (I), the limit equations are the Flory equations: a giant particle appears at time $T_{\text {gel }}$ and then coexists with other particles (finite particles do coalesce with the giant particle). In the regime (II), the limit equations are closer to the Smoluchowski equations: a giant particle appears at time $T_{\text {gel }}$ (the same one as previously) but once it is giant, it is replaced by particles with mass 1 (in a conservative way). In the regimes (III) and (IV), some other modifications of the Smoluchowski equations appear.

The most interesting results obtained by Ráth-Tóth in [55] are that in the regime (III), the modified Smoluchowski coagulation system has a unique solution which is the classical one for all $t<T_{\text {gel }}$ and has a particular (critical-like) form for $t>T_{\text {gel }}$, and $\left(c_{n, k}(t)\right)_{t \geq 0, k \geq 1}$ converges to this unique solution as $n \rightarrow \infty$. This shows that the complete graph exhibits self-organized criticality in the sense that beyond $T_{\text {gel }}$, it remains critical forever: no giant component appears but, after $T_{\text {gel }}$, the size-distribution is, in some sense, critical.
1.1.3.5. Stationary measures. - The existence of invariant measures for the forestfire process in $\mathbb{Z}^{d}$ (with any $\lambda>0$ fixed) has been proved by Stahl [60]. For the case of $\mathbb{Z}$ the situation is simpler, see the next subsection.
1.1.4. Forest fire on $\mathbb{Z}$. - Let us review in details known results about the forest fire processes in dimension 1. We still focus on the usual case where seeds and matches fall according to i.i.d. Poisson processes, with respective rates 1 and $\lambda>0$. We denote $\eta_{t}^{\lambda} \in\{0,1\}^{\mathbb{Z}}$ the configuration at time $t$ and, for $i \in \mathbb{Z}, C\left(\eta_{t}^{\lambda}, i\right)$ is the connected component of occupied sites around $i$. Observe that (possible) infinite clusters in the initial configuration would immediately disappear.

From the point of view of self-organized criticality, the interesting regime is the asymptotic behavior of the forest-fire process as $\lambda \rightarrow 0$ : then fires are very rare, but concern huge occupied components.
1.1.4.1. Stationary measures. - Existence of a stationary measure does not immediately follow from standard compactness arguments since the process is not Feller. However, in $[\mathbf{1 7}]$, Brouwer and Pennanen prove the existence of a stationary measure for all fixed $\lambda>0$. In [14], we proved the uniqueness of this invariant distribution, as well as the exponential convergence to equilibrium in the special case where $\lambda=1$. We also proved that the invariant distribution is (spatially) exponentially mixing and can be graphically constructed. The methods in [14] should be easily extended to the case where $\lambda \geq 1$ (and actually to $\lambda>1-\varepsilon_{0}$ for some rather small $\varepsilon_{0}>0$ ) but our proof completely breaks down for small values of $\lambda>0$.
1.1.4.2. Asymptotic density. - Van den Berg and Járai study in [9] the asymptotic density of vacant sites in the limit $\lambda \rightarrow 0$. Their result states that there are two constants $0<c<C$ such that for any initial configuration, for any $\lambda>0$ small
enough, for $t$ large enough (of order $\log (1 / \lambda)$ ),

$$
\frac{c}{\log (1 / \lambda)} \leq \operatorname{Pr}\left[\eta_{t}^{\lambda}(0)=0\right] \leq \frac{C}{\log (1 / \lambda)}
$$

This is coherent with the intuition that the rarer fires are, the more space is occupied by trees (although because of the lack of monotonicity, this is not straightforward). We mentioned that such result was stated in Drossel-Clar-Schwabl [28]. But the proof in [28] is not rigorous: it is based on the ansatz that the cluster sizes were following a cutoff power law, for cluster-sizes up to some $s_{\max }^{\lambda}$ defined by $s_{\max }^{\lambda} \log s_{\max }^{\lambda}=1 / \lambda$, i.e.

$$
s_{\max }^{\lambda} \simeq \frac{1}{\lambda \log (1 / \lambda)}
$$

In [9], van den Berg and Járai also show that the cluster sizes cannot follow the predicted power law.
1.1.4.3. Sizes of clusters, first results. - In [17], Brouwer and Pennanen show that this last ansatz holds true up to $s_{\text {max }}^{\frac{1}{3}}$. More specifically, they show that there are constants $0<c<C$ such that for all $0<\lambda<1$ and all stationary measures $\mu_{\lambda}$ (invariant by translation) of the forest fire model on $\mathbb{Z}$ with parameter $\lambda$, for all $x<\left(s_{\max }^{\lambda}\right)^{\frac{1}{3}}$,

$$
\frac{c}{(1+x) \log (1 / \lambda)} \leq \mu_{\lambda}(|C(\eta, 0)|=x) \leq \frac{C}{(1+x) \log (1 / \lambda)}
$$

Observe that this estimate is valid for relatively small clusters that will not be seen after rescaling (microscopic clusters).
1.1.4.4. Kingman's Process. - We detail a classical construction related to the Smoluchowski equation with constant kernel which is quite close to our point of view. Most ideas and references for proofs can be found in Aldous [2]. Let us consider the following percolation process on $\mathbb{Z}$. Starting from the vacant configuration, we let appear trees at each site at some rate $r(t)$, that allows us to control the speed of the process. Say that each edge $(i, i+1)$ has mass 1 (see subsubsection 1.1.2.4). Let a seed fall on each site $i$ at some random time $T_{i}$ with $P\left(T_{i}>t\right)=2 /(t+2)$ independently (this corresponds to the rate $r(t)=1 /(t+2)$, because then $\left.\exp \left(-\int_{0}^{t} r(s) \mathrm{d} s\right)=2 /(t+2)\right)$. Call $D(t, i)$ the particle containing the edge $(i, i+1)$ at time $t$ (say that two neighbor edges $(j-1, j)$ and $(j, j+1)$ are glued if $\eta_{t}(j)=1$ ). At time $t$, the particle containing a given edge (e.g. $\left.(0,1)\right)$ has mass $m$ with probability

$$
\rho_{m}(t)=m\left(\frac{2}{2+t}\right)^{2}\left(\frac{t}{2+t}\right)^{m-1}
$$

and hence the concentration of clusters with mass $m$ per unit length is nothing but

$$
c_{m}(t)=\left(\frac{2}{2+t}\right)^{2}\left(\frac{t}{2+t}\right)^{m-1}
$$

We recognize the solution to Smoluchowski's equation with constant coagulation kernel and mono-disperse initial condition, see Aldous [2].

Now consider a standard construction of the so-called Kingman coalescent process. Take independent exponential random variables $\left\{\xi_{k}, k \geq 2\right\}$ of rates $\binom{2}{k}$. Since $E\left[\sum_{k=2}^{\infty} \xi_{k}\right]=2$, we can define random times $0<\cdots<\tau_{3}<\tau_{2}<\tau_{1}<\infty$ by

$$
\tau_{i}=\sum_{k=i+1}^{\infty} \xi_{k} .
$$

Take $\left\{U_{i}, i \geq 1\right\}$ independent random variables uniformly distributed on $(0,1)$. For each $i$ draw a vertical segment from $\left(U_{i}, \tau_{i}\right)$ to $\left(U_{i}, 0\right)$. At time $t$ this construction splits $(0,1)$ into $i$ intervals, where $\tau_{i}<t<\tau_{i-1}$. Write $X(t)$ for the list of the lengths of these subintervals. This is a version of the stochastic coalescent called Kingman's coalescent. Observe that we also could have put the marks $\left\{\left(U_{i}, \tau_{i}\right), i \geq 1\right\}$ using a Poisson measure on $[0,1] \times \mathbb{R}_{+}$with a well-chosen intensity measure.

Straightforward computations show that Kingman's coalescent is a limit of the previously defined percolation process in the following sense: consider the list of (distinct) normalized clusters $\lambda D(t / \lambda,\lfloor x / \lambda\rfloor)$ when $x$ runs along $[0,1]$ (cutoff the boundary clusters at 0 and 1) at time $t$. When $\lambda \rightarrow 0$, it converges to $X(t)$ in law (in an appropriate topology). This construction shows how the growth process behaves in the large scales. In some sense we have identified $\left\{0, \ldots, \boldsymbol{n}_{\lambda}\right\} \subset \mathbb{Z}$ with $[0,1] \subset \mathbb{R}$ (here $\boldsymbol{n}_{\lambda}=1 / \lambda$ ) and obtained a limiting process for the rescaled percolation process.

We stress the fact that the convergence holds globally only for the specific speed $r(t)=1 /(t+2)$ of the percolation process. This fact is related to the self-similarity of the percolation (coalescent) process. In particular, for a constant rate (exponential times for seeds), there is no hope for such a convergence to Kingman's coalescent: after normalization, the size of clusters at time $t$ is of order $\lambda^{1-t}$ and converges to 0 or $\infty$ according to whether $t<1$ or $t>1$. Conversely, if the rate of growth has a polynomial decay, there is a hope to have a limit process.
1.1.4.5. Asymptotic regime: relevant space/time scales. - As already mentioned, we are interested in the behavior of the system in the large space and time scales in the limit $\lambda \rightarrow 0$. Hence the first difficulty is to decide what the relevant scales are. Let us recall the heuristic developed in [15]. We need a time scale for which tree clusters see about one fire per unit of time. But for $\lambda$ very small, clusters will be very large just before they burn. We thus also have to rescale space, in order that just before burning, clusters have a size of order 1.

Consider the cluster $C\left(\eta_{t}^{\lambda}, 0\right)$ around the site 0 (for example) at time $t$. For $\lambda>0$ very small and for $t$ not too large, one might neglect fires and consider only the growth process; it follows that $\left|C\left(\eta_{t}^{\lambda}, 0\right)\right| \simeq \mathrm{e}^{t}$ for $t$ not too large (because since seeds fall according to Poisson processes with rate 1 , each site is vacant at time $t$ with probability $\left.\mathrm{e}^{-t}\right)$. Then the cluster $C\left(\eta_{t}^{\lambda}, 0\right)$ burns at rate $\lambda\left|C\left(\eta_{t}^{\lambda}, 0\right)\right| \simeq \lambda \mathrm{e}^{t}$, so that we decide to accelerate time by a factor $\boldsymbol{a}_{\lambda}:=\log (1 / \lambda)$. By this way, $\lambda\left|C\left(\eta_{a_{\lambda}}^{\lambda}, 0\right)\right| \simeq 1$.

Now we rescale space in such a way that during a time interval of order $\boldsymbol{a}_{\lambda}$, something like one match falls per unit of (space) length. Since matches fall at rate $\lambda$ on each site, our space scale has to be of order $\boldsymbol{n}_{\lambda}:=1 /\left(\lambda \boldsymbol{a}_{\lambda}\right)$ : this means that we will identify $\left\{0, \ldots, \boldsymbol{n}_{\lambda}\right\} \subset \mathbb{Z}$ with $[0,1] \subset \mathbb{R}$. Observe that there holds $\boldsymbol{n}_{\lambda} \simeq s_{\max }^{\lambda}$, where $s_{\max }^{\lambda}$ was introduced in subsubsection 1.1.4.2.

Consider now the time/space rescaled cluster around 0

$$
D_{t}^{\lambda}(0)=\frac{1}{\boldsymbol{n}_{\lambda}} C\left(\eta_{a_{\lambda} t}^{\lambda}, 0\right) .
$$

The same difficulty as in subsubsection 1.1.4.4 appears: neglecting fires (which is roughly valid for small values of $t$ ), we see that

$$
\left|D_{t}^{\lambda}(0)\right| \simeq \boldsymbol{n}_{\lambda}^{-1} \mathrm{e}^{a_{\lambda} t}=\lambda^{1-t} \log (1 / \lambda)
$$

which goes to 0 for $t<1$ and to $\infty$ for $t \geq 1$. For $t \geq 1$, we hope that fires will be in effect, which will limit the size of clusters. But for $t<1,\left|D_{t}^{\lambda}(0)\right|$ will indeed tend to 0 . This means that we have lost some information. To describe the limit process, we have to keep in mind more information and thus introduce another quantity (a sort of degree of smallness) which measures the order of magnitude of the microscopic clusters, that is clusters that we can not see at macroscopic scales (of which the sizes are much smaller than $\boldsymbol{n}_{\lambda}$ ).
1.1.4.6. Limit processes. - We have proved in [15] that in the asymptotic of rare matches, the forest fire process converges, under the previously described normalization, to some limit forest fire process. We described precisely the dynamics of this limit process and have shown that it is unique, that it can be built by using a graphical construction and thus can be perfectly simulated. Using the limit process, we have also estimated the size of clusters. Very roughly, we have proved that in a very weak sense, for $\lambda$ small enough and for $t$ large enough (of order $\log (1 / \lambda)$ ), the cluster-size distribution resembles

$$
\operatorname{Pr}\left[C\left(\eta_{t}^{\lambda}, 0\right)=x\right] \simeq \frac{a}{(x+1) \log (1 / \lambda)} \mathbb{1}_{\left\{x \ll n_{\lambda}\right\}}+\frac{b \mathrm{e}^{-x / n_{\lambda}}}{n_{\lambda}},
$$

where $a, b$ are two positive constants. Very roughly, we are able to replace the condition $x<\left(s_{\max }^{\lambda}\right)^{\frac{1}{3}}$ of $[\mathbf{1 7}]$ by the condition $x<\left(s_{\max }^{\lambda}\right)^{1-\varepsilon}$ for any $\varepsilon \in(0,1)$ (but our result is weaker, in the sense that it holds when integrated in $x$, and we have to take the limit $\lambda \rightarrow 0$ ). This means that there are two types of clusters: microscopic clusters, described by a power-like law and macroscopic clusters, described by an exponential-like law. This shows a phase transition around the critical size $\boldsymbol{n}_{\lambda}$.
1.1.4.7. No self-organized criticality. - From the qualitative point of view the conclusion is rather different from that of Ráth and Tóth [55] (presented in subsubsection 1.1.3.4). Here, the (asymptotic) cluster-size distribution does not exhibit selforganized criticality features. We proved the presence of a power law, but this power
law describes clusters which are much smaller than the critical size. Large clusters (clusters near the critical size) have a law with fast decay.
1.1.5. Main ideas of the present paper. - From the modelling point of view, the Poisson assumption is quite reasonnable for ignitions, but clearly not well justified for recoveries (seeds). Thus it seems interesting to study what happens when seeds and matches are driven by other renewal processes. The goal of this paper is to extend the previous study [15] described above to a more general class of renewal processes. We assume that the renewal processes are stationary for simplicity, but this can be more or less justified by the fact that it is the only way that time 0 does not play a special role.

We thus consider the case where seeds (respectively matches) fall on each site of $\mathbb{Z}$ independently, according to some stationary renewal processes, with stationary delay distributed according to some law $\nu_{S}$ (respectively $\nu_{M}^{\lambda}$ ). This means that for any time $t \geq 0$ and on any site $i \in \mathbb{Z}$, the time we have to wait for the next seed is a $\nu_{S^{-}}$ distributed random variable. We have an assumption saying that as $\lambda \rightarrow 0$, matches are rarer and rarer. We also assume that $\nu_{S}$ has a bounded support or a tail with fast or regular or slow variations. We prove that, after re-scaling, the corresponding forest fire process converges, as $\lambda \rightarrow 0$, to a limit process. And we show that there are four classes of limit processes, according to the fact that
$\triangleright \nu_{S}$ has a bounded support $(H S(B S))$,
$\triangleright \nu_{S}$ has a tail with fast decay $(H S(\infty))$,
$\triangleright \nu_{S}$ has a tail with polynomial decay $(H S(\beta))$,
$\triangleright \nu_{S}$ has a tail with logarithmic decay $(H S(0))$.
As we will see, the limit forest fire process built in [15] is quite universal: it describes the asymptotics of a large class (roughly exponential decay for $\nu_{S}$ ) of forest fire processes. A similar limit process arises when $\nu_{S}$ has bounded support. But some quite different limit processes arise when $\nu_{S}$ has a heavy tail. We also develop the necessary tools to study the cluster size distributions. Let us mention at once that there is indeed presence of a critical size under $(H S(B S))$ and $(H S(\infty))$ but not under $(H S(\beta))$ or $(H S(0))$. In the latter situation, there are only macroscopic clusters. This is related to subsubsection 1.1.4.4.

It is striking that in [15] we made repeated use of the Markov property of Poisson processes while it turns out the result still holds without this assumption (and with no significant increase of the complexity). Indeed, proofs remain essentially elementary except maybe from the combinatorial and computational point of view.

From the qualitative point of view, the main novelty is the rise of a new class of processes (those corresponding to polynomial tails), reminiscent of the Kingman coalescent (with deaths). But for this case as for the others, the conclusion is that, as
expected, self-organized criticality features do not show up for this model in dimension 1.

Let us finally insist on the fact that surprisingly (in view of the complexity and length of the proofs), our assumptions are really light. Consider e.g. the case where $\nu_{S}$ has an unbounded support and a fast decay, which means (for us) that for any $t>0$,

$$
\lim _{x \rightarrow \infty} \frac{\nu_{S}((x, \infty))}{\nu_{S}((t x, \infty))}=t^{\infty}
$$

where $t^{\infty}=0$ if $t<1,1^{\infty}=1$, and $t^{\infty}=\infty$ if $t>1$. We do not need the least additional condition.
1.1.6. Plan of the paper. - Chapter 2 is devoted to a complete exposition of our results. We start in section 2.1 with notation and with the definitions of the objects under study, and we state our assumptions. In section 2.2 , we explain the heuristic scales and the relevant quantities (rescaled macroscopic clusters and measure of microscopic clusters). Then we describe precisely our results in sections 2.3 (case with fast decay), 2.4 (case with bounded support), 2.5 (case with polynomial decay) and 2.6 (case with logarithmic decay). We conclude this part with a quick discussion about our modeling choices and with a short list of open problems and perspectives. Chapter 3 (sections 3.1 to 3.11 ) contains all the proofs. In Chapter 4 we handle a few numerical simulations to illustrate our results. Finally, Chapter 5 contains an appendix about regularly varying functions and coupling.

## CHAPTER 2

## NOTATION AND RESULTS

### 2.1. Definitions, notation and assumptions

2.1.1. Stationary renewal processes. - We first fix notation about stationary renewal processes. We refer to Cocozza-Thivent $[\mathbf{2 1}]$ for a book on renewal processes.

Definition 2.1.1. - For $\mu$ a probability measure on $(0, \infty)$ with finite expectation $m_{\mu}$, set

$$
\nu_{\mu}(\mathrm{d} t)=m_{\mu}^{-1} \mu((t, \infty)) \mathrm{d} t
$$

which is also a probability measure on $(0, \infty)$. Let $T_{1}$ be a $\nu_{\mu}$-distributed random variable and let $\left(X_{k}\right)_{k \geq 1}$ be a sequence of i.i.d. random variables with law $\mu$, independent of $T_{1}$. Set

$$
T_{k+1}=T_{k}+X_{k} \text { for all } k \geq 1 \quad \text { and } \quad N_{t}=\sum_{k \geq 1} \mathbb{1}_{\left\{T_{k} \leq t\right\}} \text { for all } t \geq 0 .
$$

We say that $\left(N_{t}\right)_{t \geq 0}$ is a stationary renewal process with parameter $\mu$, or a $\operatorname{SR}(\mu)$ process in short.

It is well-known, see e.g. [21, Corollaire 6.19, p. 169], that for $\left(N_{t}\right)_{t \geq 0}$ a $\operatorname{SR}(\mu)$ process in the sense of Definition 2.1.1, the law of $T_{N_{t}+1}-t$ (i.e. the time we have to wait for the next mark at time $t$ ) is $\nu_{\mu}$ for all $t \geq 0$. Another possible definition is the following.

Definition 2.1.2. - For $\mu$ a probability measure on $(0, \infty)$ with finite expectation $m_{\mu}$, set

$$
\nu_{\mu}(\mathrm{d} t)=m_{\mu}^{-1} \mu((t, \infty)) \mathrm{d} t \quad \text { and } \quad \zeta_{\mu}(\mathrm{d} t)=m_{\mu}^{-1} t \mu(\mathrm{~d} t),
$$

which are also probability measures on $(0, \infty)$. Consider a collection of random variables $\left(X_{i}\right)_{i \in \mathbb{Z} \backslash\{0\}}$ with law $\mu$. Consider also $X_{0}$ with law $\zeta_{\mu}$ and $U$ uniformly distributed on $[0,1]$. Assume that all these random variables are independent. Define

$$
T_{0}=-(1-U) X_{0}, \quad T_{1}=U X_{0}
$$

and then, for $n \geq 1$,

$$
T_{n+1}=T_{n}+X_{n} \quad \text { and } \quad T_{-n}=T_{-(n-1)}-X_{-n} .
$$

Then we say that $\left(T_{n}\right)_{n \in \mathbb{Z}}$ is a $\operatorname{SR}(\mu)$-process.
If $\left(T_{n}\right)_{n \in \mathbb{Z}}$ is a $\operatorname{SR}(\mu)$-process in the sense of Definition 2.1.2 and if one considers the associated counting process $N_{t}=\sum_{n \geq 1} \mathbb{1}_{\left\{T_{n} \leq t\right\}}$, it is indeed a $\operatorname{SR}(\mu)$-process in the sense of Definition 2.1.1. This can be checked immediately: it suffices to observe that the law of $T_{1}$ is $\nu_{\mu}$.

If we have a $\operatorname{SR}(\mu)$-process $\left(N_{t}\right)_{t \geq 0}$ as in Definition 2.1.1 and if we denote by $\left(T_{n}\right)_{n \geq 1}$ its successive instants of jump, one can easily build $\left(T_{n}\right)_{n \leq 0}$ in such a way that $\left(T_{n}\right)_{n \in \mathbb{Z}}$ is a $\operatorname{SR}(\mu)$-process as in Definition 2.1.2.

For $\left(T_{n}\right)_{n \in \mathbb{Z}}$ a $\operatorname{SR}(\mu)$-process as in Definition 2.1.2, for any $t \in \mathbb{R}$, the random sets

$$
\bigcup_{n \in \mathbb{Z}}\left\{T_{n}\right\}, \quad \bigcup_{n \in \mathbb{Z}}\left\{-T_{n}\right\} \quad \text { and } \quad \bigcup_{n \in \mathbb{Z}}\left\{T_{n}+t\right\}
$$

have the same law. Thus if we introduce $n_{t}$ such that $T_{n_{t}}+t<0<T_{n_{t}+1}+t$, the process $\left(T_{n_{t}+n}+t\right)_{n \in \mathbb{Z}}$ is a $\operatorname{SR}(\mu)$-process. By the same way, the process $\left(-T_{1-n}\right)_{n \in \mathbb{Z}}$ is a $\operatorname{SR}(\mu)$-process.
2.1.2. The discrete model. - Next, we introduce the forest fire model. For $a, b \in \mathbb{Z}$ with $a \leq b$, we set

$$
\llbracket a, b \rrbracket=\{a, \ldots, b\} \subset \mathbb{Z}
$$

For $\eta \in\{0,1\}^{\mathbb{Z}}$ and $i \in \mathbb{Z}$, we define the occupied connected component around $i$ as

$$
C(\eta, i)= \begin{cases}\varnothing & \text { if } \eta(i)=0, \\ \llbracket \ell(\eta, i), r(\eta, i) \rrbracket & \text { if } \eta(i)=1,\end{cases}
$$

where $\ell(\eta, i)=\sup \{k<i: \eta(k)=0\}+1$ and $r(\eta, i)=\inf \{k>i: \eta(k)=0\}-1$.
Definition 2.1.3. - Let $\mu_{S}$ and $\mu_{M}$ be two laws on $(0, \infty)$ with finite expectations. For each $i \in \mathbb{Z}$, we consider a $\operatorname{SR}\left(\mu_{S}\right)$-process $\left(N_{t}^{S}(i)\right)_{t \geq 0}$ and a $\mathrm{SR}\left(\mu_{M}\right)$-process $\left(N_{t}^{M}(i)\right)_{t \geq 0}$, all these processes being independent. A $\{0,1\}$-valued process $\left(\eta_{t}(i)\right)_{i \in \mathbb{Z}, t \geq 0}$ such that $\left(\eta_{t}(i)\right)_{t \geq 0}$ is a.s. càdlàg for all $i \in \mathbb{Z}$ is said to be a $\mathrm{FF}\left(\mu_{S}, \mu_{M}\right)$-process if a.s., for all $t \geq 0$, all $i \in \mathbb{Z}$,

$$
\eta_{t}(i)=\int_{0}^{t} \mathbb{1}_{\left\{\eta_{s-}(i)=0\right\}} \mathrm{d} N_{s}^{S}(i)-\sum_{j \in \mathbb{Z}} \int_{0}^{t} \mathbb{1}_{\left\{j \in C\left(\eta_{s-}, i\right)\right\}} \mathrm{d} N_{s}^{M}(j) .
$$

Formally, we say that $\eta_{t}(i)=0$ if there is no tree at site $i$ at time $t$ and $\eta_{t}(i)=1$ else. Thus the forest fire process starts from an empty initial configuration, seeds fall according to i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes and matches fall according to i.i.d. $\operatorname{SR}\left(\mu_{M}\right)$ processes. When a seed falls on an empty site, a tree appears immediately. When a match falls on an occupied site, it burns immediately the corresponding connected

Figure 1. Graphical construction of the $\mathrm{FF}\left(\mu_{S}, \mu_{M}\right)$-process.
Matches are represented as bullets and seeds as squares. On the sites -5 and 6 , no seed fall during $[0, T]$, so that these sites remain vacant until $T$. One can thus clearly deduce the values of the process in $\llbracket-5,6 \rrbracket$ during $[0, T]$ using only the bullets and squares inside $\llbracket-5,6 \rrbracket$.
component of occupied sites. Seeds falling on occupied sites and matches falling on vacant sites have no effect.

Assume for a moment that the support of $\mu_{S}$ is unbounded (thus so is that of $\left.\nu_{\mu_{S}}\right)$. Then the $\operatorname{FF}\left(\mu_{S}, \mu_{M}\right)$-process can be shown to exist and to be unique (for almost every realization of $\left.\left(N_{t}^{S}(i), N_{t}^{M}(i)\right)_{i \in \mathbb{Z}, t \geq 0}\right)$, by using a genuine graphical construction. Indeed, to build the process until a given time $T>0$, it suffices to work between sites $i$ which are vacant until time $T$ (because $N_{T}^{S}(i)=0$ ). Interaction cannot cross such sites. Since such sites are a.s. infinitely many (because $\operatorname{Pr}\left[N_{T}^{S}(i)=0\right]=\nu_{\mu_{S}}((T, \infty))>0$ by assumption $)$, this allows us to handle a graphical construction. This is illustrated by Figure 1. See Liggett [45] for many examples of graphical constructions.

We will also study the more complicated case where $\mu_{S}$ has a bounded support and this will lead to the following general result.

Proposition 2.1.4. - Let $\mu_{S}$ and $\mu_{M}$ be two laws on $(0, \infty)$ with some finite expectations. For each $i \in \mathbb{Z}$, we consider a $\operatorname{SR}\left(\mu_{S}\right)$-process $\left(N_{t}^{S}(i)\right)_{t \geq 0}$ and a $\operatorname{SR}\left(\mu_{M}\right)$ process $\left(N_{t}^{M}(i)\right)_{t \geq 0}$, all these processes being independent. Almost surely, there exists a unique $\operatorname{FF}\left(\mu_{S}, \mu_{M}\right)$-process.

This proposition is proved in section 3.1.
2.1.3. Assumptions. - We now state the assumptions we will impose on the laws $\mu_{S}$ and $\mu_{M}$. First, we want to express the fact that matches are less and less frequent. To do so, we consider a family of laws $\mu_{M}^{\lambda}$, for $\lambda \in(0,1]$, as follows.

$$
\left(H_{M}\right)\left\{\begin{array}{l}
\text { For each } \lambda \in(0,1], \mu_{M}^{\lambda} \text { is the image measure of } \mu_{M}^{1} \text { by the } \\
\text { map } t \mapsto t / \lambda \text { and the probability measure } \mu_{M}^{1} \text { on }(0, \infty) \\
\text { satisfies } \int_{0}^{\infty} t \mu_{M}^{1}(\mathrm{~d} t)=1 \text {. We set } \\
\nu_{M}^{\lambda}(\mathrm{d} t)=\nu_{\mu_{M}^{\lambda}}(\mathrm{d} t)=\lambda \mu_{M}^{\lambda}((t, \infty)) \mathrm{d} t=\lambda \mu_{M}^{1}((\lambda t, \infty)) \mathrm{d} t
\end{array}\right.
$$

The idea we have in mind is that we slow down matches: for $\left(N_{t}^{M}\right)_{t \geq 0}$ a $\operatorname{SR}\left(\mu_{M}^{1}\right)$ process, $\left(N_{\lambda t}^{M}\right)_{t \geq 0}$ is a $\mathrm{SR}\left(\mu_{M}^{\lambda}\right)$-process.

Assume that $\int_{0}^{\infty} t \mu_{M}^{1}(\mathrm{~d} t)=\kappa \in(0, \infty)$. Then $\widetilde{\mu}_{M}^{\lambda}=\mu_{M}^{\kappa \lambda}$ satisfies $\left(H_{M}\right)$. We thus may of course assume that $\kappa=1$ without loss of generality.

Next, we put some conditions about $\mu_{S}$.

$$
\left(H_{S}\right)\left\{\begin{array}{l}
\text { The probability measure } \mu_{S} \text { on }(0, \infty) \text { has a finite mean } \\
m_{S}=\int_{0}^{\infty} t \mu_{S}(\mathrm{~d} t) . \text { We set } \\
\quad \nu_{S}(\mathrm{~d} t)=\nu_{\mu_{S}}(\mathrm{~d} t)=m_{S}^{-1} \mu_{S}((t, \infty)) \mathrm{d} t \\
\text { Either } \mu_{S} \text { has a bounded support or } \mu_{S} \text { has an unbounded } \\
\text { support and } \\
\quad \forall t>0, \quad \lim _{x \rightarrow \infty} \frac{\nu_{S}((x, \infty))}{\nu_{S}((t x, \infty))} \in[0, \infty) \cup\{\infty\} \quad \text { exists. }
\end{array}\right.
$$

Surprisingly, we will consider these assumptions in full generality: no supplementary technical condition is needed. In the whole paper, we admit the following convention:

$$
t^{\infty}= \begin{cases}0 & \text { if } t \in(0,1) \\ 1 & \text { if } t=1 \\ \infty & \text { if } t \in(1, \infty)\end{cases}
$$

As proved in Lemma 5.1.1, $\left(H_{S}\right)$ implies either

$$
\left(H_{S}(B S)\right)\left\{\begin{array}{l}
\text { The probability measure } \mu_{S} \text { on }(0, \infty) \text { has a bounded sup- } \\
\text { port. We denote by } m_{S} \text { the expectation of } \mu_{S} \text { and define } \\
T_{S}=\max \operatorname{supp} \mu_{S} \text { and } \nu_{S}(\mathrm{~d} t)=m_{S}^{-1} \mu_{S}((t, \infty)) \mathrm{d} t . \text { Ob- } \\
\text { serve that } \operatorname{supp} \nu_{S}=\left[0, T_{S}\right]
\end{array}\right.
$$ or, for some $\beta \in[0, \infty) \cup\{\infty\}$,

$$
\left(H_{S}(\beta)\right)\left\{\begin{array}{l}
\text { The probability measure } \mu_{S} \text { on }(0, \infty) \text { has an un- } \\
\text { bounded support, a finite mean } m_{S} \text { and for } \nu_{S}(\mathrm{~d} t)= \\
m_{S}^{-1} \mu_{S}((t, \infty)) \mathrm{d} t, \\
\forall t>0, \quad \lim _{x \rightarrow \infty} \frac{\nu_{S}((x, \infty))}{\nu_{S}((t x, \infty))}=t^{\beta} .
\end{array}\right.
$$

We finally introduce the following notation.
notation 2.1.5. - (i) Assume $\left(H_{S}(\beta)\right)$ for some $\beta \in[0, \infty)$. We denote by $\phi_{S}$ the inverse function of $t \mapsto t / \nu_{S}((t, \infty))$. Note that $\phi_{S}:(0, \infty) \mapsto(0, \infty)$ is an increasing continuous bijection.
(ii) Assume $\left(H_{S}(\infty)\right)$. We denote by $\phi_{S}$ the inverse function of $t \mapsto t / \nu_{S}((t, \infty))$ and by $\psi_{S}$ the inverse function of $t \mapsto \nu_{S}((0, t))$. The functions $\phi_{S}:(0, \infty) \mapsto(0, \infty)$ and $\psi_{S}:(0,1) \mapsto(0, \infty)$ are increasing bijections.
(iii) Assume $\left(H_{S}(B S)\right)$. We denote by $\psi_{S}$ the inverse function of $t \mapsto \nu_{S}((0, t))$. The function $\psi_{S}:(0,1) \mapsto\left(0, T_{S}\right)$ is an increasing continuous bijection.
2.1.4. Examples. - Concerning $\left(H_{M}\right)$, the situation is clear. The Poisson case studied in [15] corresponds to $\mu_{M}^{1}(\mathrm{~d} t)=\mathrm{e}^{-t} \mathbf{1}_{\{t>0\}} \mathrm{d} t$, whence

$$
\mu_{M}^{\lambda}(\mathrm{d} t)=\nu_{M}^{\lambda}(\mathrm{d} t)=\lambda \mathrm{e}^{-\lambda t} \mathbb{1}_{\{t>0\}} \mathrm{d} t
$$

We study here a much more general case. However, this is not the main point of the paper, since it will not generate some very interesting behaviors. Concerning $\left(H_{S}\right)$, we present here four classes of examples, that will lead to different behaviors.

Example 1. - If $\mu_{S}=\delta_{T_{S}}$, whence $\nu_{S}(\mathrm{~d} t)=T_{S}^{-1} \mathbb{1}_{\left[0, T_{S}\right]}(t) \mathrm{d} t$, then $\left(H_{S}(B S)\right)$ holds and $\psi_{S}(z)=T_{S} z$.

Example 2. - Assume that $\mu_{S}((t, \infty)) \stackrel{\infty}{\sim} \mathrm{e}^{-t^{\alpha}}$ for some $\alpha>0$, so that $\nu_{S}((t, \infty)) \stackrel{\infty}{\sim}$ $c t^{1-\alpha} \mathrm{e}^{-t^{\alpha}}$. Then $\left(H_{S}(\infty)\right)$ holds. Furthermore, $\phi_{S}(z) \stackrel{\infty}{\sim}(\log z)^{1 / \alpha}$ and $\psi_{S}(z) \stackrel{1}{\sim}$ $[\log (1 /(1-z))]^{1 / \alpha}$.

Example 3. - Assume that $\mu_{S}((t, \infty)) \stackrel{\infty}{\sim} t^{-1-\beta}$ for some $\beta>0$, whence $\nu_{S}((t, \infty)) \stackrel{\infty}{\sim} c t^{-\beta}$. Then $\left(H_{S}(\beta)\right)$ holds and $\phi_{S}(z) \stackrel{\infty}{\sim}(c z)^{1 /(\beta+1)}$.

Example 4. - If $\mu_{S}((t, \infty)) \stackrel{\infty}{\sim} t^{-1}(\log t)^{-1-\gamma}$ for some $\gamma>0$, then $\nu_{S}((t, \infty)) \stackrel{\infty}{\sim}$ $c(\log t)^{-\gamma}$, so that $\left(H_{S}(0)\right)$ is satisfied and $\phi_{S}(z) \stackrel{\infty}{\sim} c z(\log z)^{-\gamma}$.

The Poisson case treated in [15], which corresponds to the case where $\mu_{S}((t, \infty))=$ $\mathrm{e}^{-t}=\nu_{S}((t, \infty))$, is thus included in Example 2. Example 1 might seem slightly strange from the modelling point of view, but it can happen e.g. if seeds are thrown by a machine.

Observe that $\left(H_{S}\right)$ is not very restrictive, since it is satisfied by all reasonable laws. Anyway, our results (not only the proofs) clearly break down without such an assumption.

It is not so easy to build a law $\mu_{S}$ not meeting $\left(H_{S}\right)$, because $t \mapsto \nu_{S}((t, \infty))$ is automatically quite smooth (Lipschitz continuous, decreasing and convex). One can however verify that $\left(H_{S}\right)$ is not holding for

$$
\left.\mu_{S}(\mathrm{~d} t)=\mathbb{1}_{\{t>0\}}[20-3 \cos \log (1+t)+\sin \log (1+t)] /\left[9(1+t)^{3}\right)\right] \mathrm{d} t
$$

for which $\nu_{S}((t, \infty))=[10+\sin \log (1+t)] /[10(1+t)]$. One easily checks that $\nu_{S}((x, \infty)) / \nu_{S}\left(\left(x \mathrm{e}^{\pi / 2}, \infty\right)\right)$ has no limit as $x \rightarrow \infty$, choosing e.g. the sequences $x_{n}=\mathrm{e}^{2 n \pi}$ and $x_{n}=\mathrm{e}^{2 n \pi+\pi / 2}$.
2.1.5. Notation. - We denote:
$\triangleright$ for $I \subset \mathbb{Z}$, by $|I|=\# I$ the number of elements in $I$;
$\triangleright$ for $I=\llbracket a, b \rrbracket=\{a, \ldots, b\} \subset \mathbb{Z}$ and $\alpha>0$, we will set $\alpha I:=[\alpha a, \alpha b] \subset \mathbb{R}$. For $\alpha>0$, we of course take the convention that $\alpha \varnothing=\varnothing$;
$\triangleright$ for $J=[a, b]$ an interval of $\mathbb{R},|J|=b-a$ stands for the length of $J$ and for $\alpha>0$, we set $\alpha J=[\alpha a, \alpha b]$;
$\triangleright$ for $x \in \mathbb{R},\lfloor x \mid$ stands for the integer part of $x$;
$\triangleright$ we denote by $\mathcal{I}=\{[a, b], a \leq b\}$ the set of all closed finite intervals of $\mathbb{R}$;
$\triangleright$ for two intervals $[a, b]$ and $[c, d]$, we set

$$
\boldsymbol{\delta}([a, b],[c, d])=|a-c|+|b-d|, \quad \boldsymbol{\delta}([a, b], \varnothing)=|b-a| ;
$$

$\triangleright$ for two functions $I, J:[0, T] \rightarrow \mathcal{I} \cup\{\varnothing\}$, we set

$$
\boldsymbol{\delta}_{T}(I, J)=\int_{0}^{T} \boldsymbol{\delta}\left(I_{t}, J_{t}\right) \mathrm{d} t
$$

$\triangleright$ for $(x, I),(y, J)$ in $\mathbb{D}\left([0, T], \mathbb{R}_{+} \times \mathcal{I} \cup\{\varnothing\}\right)$, the set of càdlàg functions from $[0, T]$ into $\mathbb{R}_{+} \times \mathcal{I} \cup\{\varnothing\}$, we define

$$
\boldsymbol{d}_{T}((x, I),(y, J))=\sup _{t \in[0, T]}|x(t)-y(t)|+\boldsymbol{\delta}_{T}(I, J) .
$$

### 2.2. Heuristic scales and relevant quantities

For $\mu_{S}, \mu_{M}^{\lambda}$ satisfying $\left(H_{S}\right)$ and $\left(H_{M}\right)$, we consider the $\mathrm{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. We look for some time scale for which tree clusters see about one fire per unit of time. But for $\lambda$ very small, clusters will be very large just before they burn. We thus also have to rescale space.

Time scale. - For $\lambda>0$ very small and for $t$ not too large, one might neglect fires, so that roughly, each site is vacant with probability $\nu_{S}((t, \infty))$. Indeed, the time we have to wait for the first seed follows, on each site, the law $\nu_{S}$. Thus

$$
C\left(\eta_{t}^{\lambda}, 0\right) \simeq \llbracket-X, Y \rrbracket
$$

where $X, Y$ are geometric random variables with parameter $\nu_{S}((t, \infty))$. Consequently, for $t$ not too large,

$$
\left|C\left(\eta_{t}^{\lambda}, 0\right)\right| \simeq 1 / \nu_{S}((t, \infty))
$$

Under $\left(H_{S}(B S)\right),\left|C\left(\eta_{t}^{\lambda}, 0\right)\right|$ becomes infinite at time $T_{S}$, so there is no really need to accelerate time: we are sure that $\left|C\left(\eta_{t}^{\lambda}, 0\right)\right|$ will be involved in a fire before $T_{S}$. We will accelerate time by a factor $T_{S}$ (in some sense, this allows us to assume that $T_{S}=1$ ).

Next we assume $\left(H_{S}(\beta)\right)$ for some $\beta \in[0, \infty) \cup\{\infty\}$. We observe that thanks to $\left(H_{M}\right)$,

$$
\nu_{M}^{\lambda}((t, \infty)) \simeq 1-\lambda \int_{0}^{t} \mu_{M}^{1}((\lambda s, \infty)) \mathrm{d} s \simeq 1-\lambda t
$$

Hence the probability that at least one match falls in the cluster $C\left(\eta^{\lambda}, 0\right)$ during $[0, t]$ is roughly similar, under $\left(H_{M}\right)$, to

$$
1-\left(\nu_{M}^{\lambda}((t, \infty))\right)^{\left|C\left(\eta_{t}^{\lambda}, 0\right)\right|} \simeq \lambda t\left|C\left(\eta_{t}^{\lambda}, 0\right)\right| \simeq \lambda t / \nu_{S}((t, \infty))
$$

We decide to accelerate time by a factor $\boldsymbol{a}_{\lambda}$, where $\boldsymbol{a}_{\lambda}$ solves $\lambda \boldsymbol{a}_{\lambda}=\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)$. By this way, the probability that a match falls in $C\left(\eta^{\lambda}, 0\right)$ during $\left[0, \boldsymbol{a}_{\lambda}\right]$ should tend to some nontrivial value.

To summarize, we have set, recalling notation 2.1.5 for the definition of $\phi_{S}$,

$$
\left\{\begin{array}{l}
\text { under }\left(H_{S}(B S)\right), \quad \boldsymbol{a}_{\lambda}=T_{S}  \tag{2.2.1}\\
\text { under }\left(H_{S}(\beta)\right) \text { with } \beta \in[0, \infty) \cup\{\infty\}, \quad \boldsymbol{a}_{\lambda}=\phi_{S}(1 / \lambda), \\
\text { which solves } \lambda \boldsymbol{a}_{\lambda}=\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)
\end{array}\right.
$$

Under $\left(H_{S}(\beta)\right)$ for some $\beta \in[0, \infty) \cup\{\infty\}$, one easily checks that

$$
\lim _{\lambda \rightarrow 0} \boldsymbol{a}_{\lambda}=\infty \quad \text { and thus } \quad \lim _{\lambda \rightarrow 0} \lambda \boldsymbol{a}_{\lambda}=\lim _{\lambda \rightarrow 0} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)=0
$$

Space scale. - Now we rescale space in such a way that during a time interval with length of order $\boldsymbol{a}_{\lambda}$, something like one fire starts per unit of (space) length. Since on each site, the probability that (at least) one match falls during $\left[0, a_{\lambda}\right]$ equals

$$
\nu_{M}\left(\left(0, \boldsymbol{a}_{\lambda}\right)\right)=\lambda \int_{0}^{\boldsymbol{a}_{\lambda}} \mu_{M}^{1}((\lambda t, \infty)) \mathrm{d} t \simeq \lambda \boldsymbol{a}_{\lambda}
$$

our space scale has to be of order

$$
\begin{equation*}
\boldsymbol{n}_{\lambda}=\left\lfloor 1 /\left(\lambda \boldsymbol{a}_{\lambda}\right)\right\rfloor . \tag{2.2.2}
\end{equation*}
$$

This means that we will identify $\llbracket 0, \boldsymbol{n}_{\lambda} \rrbracket \subset \mathbb{Z}$ with $[0,1] \subset \mathbb{R}$. We always have

$$
\lim _{\lambda \rightarrow 0} n_{\lambda}=\infty
$$

Rescaled clusters. - We thus set, for $\lambda \in(0,1), t \geq 0$ and $x \in \mathbb{R}$, recalling subsection 2.1.5,

$$
\begin{equation*}
D_{t}^{\lambda}(x):=\frac{1}{\boldsymbol{n}_{\lambda}} C\left(\eta_{a_{\lambda} t}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor\right) \subset \mathbb{R} \tag{2.2.3}
\end{equation*}
$$

Using the computation handled in paragraph Time scale, we see that roughly, when neglecting fires,

$$
\left|D_{t}^{\lambda}(x)\right| \simeq \frac{1}{\boldsymbol{n}_{\lambda} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)} \simeq \frac{\lambda \boldsymbol{a}_{\lambda}}{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)}
$$

Under $\left(H_{S}(\beta)\right)$ for some $\beta \in[0, \infty) \cup\{\infty\}$, one gets

$$
\left|D_{t}^{\lambda}(x)\right| \simeq \frac{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)}{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)} \simeq t^{\beta}
$$

Under $\left(H_{S}(B S)\right.$ ), we obtain roughly (assume that $t \neq 1$ )

$$
\left|D_{t}^{\lambda}(x)\right| \simeq t^{\infty} .
$$

Indeed, $\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)=\nu_{S}\left(\left(T_{S} t, \infty\right)\right)$ does not depend on $\lambda$ and is positive if and only if $t<1$.

Case $\beta \in[0, \infty)$. - In this case, everything is fine: for all times of order $\boldsymbol{a}_{\lambda} t$, the good space scale is indeed $\boldsymbol{n}_{\lambda}$. Thus we will describe the $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process through $\left(D_{t}^{\lambda}(x)\right)_{x \in \mathbb{R}, t \geq 0}$.

Case $\beta \in\{\infty, B S\}$. - Then we have a difficulty as in [15]: the previous estimate (neglecting fires) suggests that for all $x \in \mathbb{R}$, for $t<1,\left|D_{t}^{\lambda}(x)\right| \rightarrow 0$ and for $t>1$, $\left|D_{t}^{\lambda}(x)\right| \rightarrow \infty$. For $t>1$, fires might be in effect and we hope that this will make finite the possible limit of $\left|D_{t}^{\lambda}(x)\right|$. But fires can only reduce the size of clusters, so that for $t<1$, the limit of $\left|D_{t}^{\lambda}(x)\right|$ will really be 0 .

Since we would like to have an idea of the sizes of microscopic clusters, we have to keep some information about the degree of smallness of microscopic clusters. We adopt a different strategy than in [15], which is more adapted to the case where $\beta=B S$ and which leads us to a slightly more direct proof (even in the Poisson case).

We consider a function $\boldsymbol{m}_{\lambda}:(0,1] \mapsto \mathbb{N}$ satisfying

$$
\left\{\begin{array}{l}
\lim _{\lambda \rightarrow 0} \boldsymbol{m}_{\lambda}=\infty, \lim _{\lambda \rightarrow 0}\left(\boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}\right)=0  \tag{2.2.4}\\
\lambda \mapsto \boldsymbol{m}_{\lambda} \text { is non-increasing } \\
\text { and additionally, under }\left(H_{S}(\infty)\right), \\
\forall z \in[0,1), \quad \lim _{\lambda \rightarrow 0} \boldsymbol{m}_{\lambda} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} z, \infty\right)\right)=\infty
\end{array}\right.
$$

Such a function exists: under $\left(H_{S}(\infty)\right)$, see Lemma 5.1.2 and under $\left(H_{S}(B S)\right)$, choose for example $\boldsymbol{m}_{\lambda}=\lfloor\sqrt{1 / \lambda}\rfloor$.

Of course, there is no uniqueness of $\boldsymbol{m}_{\lambda}$, but that does not matter: the only thing we need is that the scale $\boldsymbol{m}_{\lambda}$ is smaller than the macroscopic scale $\boldsymbol{n}_{\lambda} \simeq 1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)$ and larger than all the microscopic scales $1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} z, \infty\right)\right.$ ) (for all $\left.z \in(0,1)\right)$. Since only these scales will appear to be relevant, any choice of such a function $\boldsymbol{m}_{\lambda}$ will be suitable.

We introduce, for $\lambda>0, x \in \mathbb{R}, t>0$, recall subsection 2.1.5 and that by notation 2.1.5, $\psi_{s}$ is the inverse of $t \mapsto \nu_{S}((0, t))$,

$$
\left\{\begin{array}{l}
K_{t}^{\lambda}(x):=\frac{\left|\left\{i \in \llbracket\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor-\boldsymbol{m}_{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor+\boldsymbol{m}_{\lambda} \rrbracket: \eta_{\boldsymbol{a}_{\lambda} t}^{\lambda}(i)=1\right\}\right|}{2 \boldsymbol{m}_{\lambda}+1} \in[0,1],  \tag{2.2.5}\\
Z_{t}^{\lambda}(x):=\frac{\psi_{S}\left(K_{t}^{\lambda}(x)\right)}{\boldsymbol{a}_{\lambda}} \wedge 1 \in[0,1] .
\end{array}\right.
$$

Observe that $K_{t}^{\lambda}(x)$ stands for the local density of occupied sites around $\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor$ at time $\boldsymbol{a}_{\lambda} t$. This density is local because $\boldsymbol{m}_{\lambda} \ll \boldsymbol{n}_{\lambda}$. We hope that for $t<1$, neglecting fires, $K_{t}^{\lambda}(x) \simeq \nu_{S}\left(\left(0, a_{\lambda} t\right)\right)$, whence $Z_{t}^{\lambda}(x) \simeq t$.

The quantity $Z_{t}^{\lambda}(x)$ has no physical interpretation. We use it to transform the local density $K_{t}^{\lambda}(x)$ (which depends on $t$ in a complicated way involving $\nu_{S}$ ) in a quantity of which the behavior does not depend too much on $\nu_{S}$ (at least for $t<1$
and neglecting fires). This will allow us to describe the limit process in an unified way (not depending on $\nu_{S}$ ).

For all $\lambda>0$ small enough (we need that $2 \boldsymbol{m}_{\lambda}+1<\boldsymbol{n}_{\lambda}$ ), we have $Z_{t}^{\lambda}(x)=1$ if and only if $K_{t}^{\lambda}(x)=1$, i.e. if and only if all the sites are occupied around $\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor$. Indeed, under $\left(H_{S}(B S)\right), Z_{t}^{\lambda}(x)=1$ implies that $\psi_{S}\left(K_{t}^{\lambda}(x)\right)=T_{S}$, so that

$$
K_{t}^{\lambda}(x)=\nu_{S}\left(\left(0, T_{S}\right)\right)=1
$$

Under $\left(H_{S}(\infty)\right), Z_{t}^{\lambda}(x)=1$ implies that $\psi_{S}\left(K_{t}^{\lambda}(x)\right) \geq \boldsymbol{a}_{\lambda}$, so that

$$
K_{t}^{\lambda}(x) \geq \nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda}\right)\right)=1-\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)=1-\lambda \boldsymbol{a}_{\lambda} \geq 1-1 / \boldsymbol{n}_{\lambda}
$$

whence $K_{t}^{\lambda}(x)=1$. This last assertion comes from the facts that $K_{t}^{\lambda}(x)$ takes its values in $\left\{k /\left(2 \boldsymbol{m}_{\lambda}+1\right): k \in\left\{0, \ldots, 2 \boldsymbol{m}_{\lambda}+1\right\}\right.$ and that $2 \boldsymbol{m}_{\lambda}+1<\boldsymbol{n}_{\lambda}$.

Since the scale $\boldsymbol{m}_{\lambda}$ is larger than all the microscopic scales, $Z_{t}^{\lambda}(x)=1$ will imply, roughly, that the cluster containing $\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor$ is macroscopic, i.e. has a length of order $\boldsymbol{n}_{\lambda}$.

We will study the $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process through $\left(D_{t}^{\lambda}(x), Z_{t}^{\lambda}(x)\right)_{x \in \mathbb{R}, t \geq 0}$. The main idea is that for $\lambda>0$ very small:
$\triangleright$ If $Z_{t}^{\lambda}(x)=z \in(0,1)$, then $\left|D_{t}^{\lambda}(x)\right| \simeq 0$ and the (rescaled) cluster containing $x$ is microscopic (in the sense that the non-rescaled cluster is small when compared to $\boldsymbol{n}_{\lambda}$ ), but we control the local density of occupied sites around $x$, which resembles $\nu_{S}\left(\left(0, a_{\lambda} z\right)\right)$. Observe that this density tends to 1 as $\lambda \rightarrow 0$ for all $z \in(0,1)$ under $\left(H_{S}(\infty)\right)$, while it remains bounded as $\lambda \rightarrow 0$ for all $z \in(0,1)$ under $\left(H_{S}(B S)\right)$.
$\triangleright$ If $Z_{t}^{\lambda}(x)=1$ and $D_{t}^{\lambda}(x)=[a, b]$, then the (rescaled) cluster containing $x$ is macroscopic and has a length equal to $b-a$, or

$$
\left|C\left(\eta_{\boldsymbol{a}_{\lambda} t}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor\right)\right| \simeq(b-a) \boldsymbol{n}_{\lambda}
$$

in the original scales.
Summary. - Assume $\left(H_{S}(\beta)\right)$ for some $\beta \in[0, \infty) \cup\{\infty, B S\}$.
$\triangleright$ We accelerate time by the factor $\boldsymbol{a}_{\lambda}$, defined by $\lambda \boldsymbol{a}_{\lambda}=\nu_{S}\left(\left(\lambda \boldsymbol{a}_{\lambda}, \infty\right)\right)$ if $\beta$ belongs to $[0, \infty) \cup\{\infty\}$ and by $a_{\lambda}=T_{S}$ if $\beta=B S$.
$\triangleright$ Our space scale is $\boldsymbol{n}_{\lambda}=\left\lfloor 1 /\left(\lambda \boldsymbol{a}_{\lambda}\right)\right\rfloor$.
$\triangleright$ If $\beta \in[0, \infty)$, we will only study the rescaled clusters $\left(D_{t}^{\lambda}(x)\right)_{t \geq 0, x \in \mathbb{R}}$, see (2.2.3).
$\triangleright$ If $\beta \in\{\infty, B S\}$, we will study the rescaled clusters $\left(D_{t}^{\lambda}(x)\right)_{t \geq 0, x \in \mathbb{R}}$, as well as the local densities of occupied sites $\left(Z_{t}^{\lambda}(x)\right)_{t \geq 0, x \in \mathbb{R}}$, see $(2.2 .4)-(2.2 .5)$.

### 2.3. Main result in the case $\beta=\infty$

2.3.1. Definition of the limit process. - We describe the limit process in the case where $\beta=\infty$. It is exactly the same process as in the Poisson case studied in [15]. We consider a Poisson measure $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)$ on $[0, \infty) \times \mathbb{R}$, with intensity measure $\mathrm{d} t \mathrm{~d} x$, whose marks correspond to matches.

Before stating a precise definition, let us describe briefly the limit process. Initially, all the sites are vacant. Matches fall according to $\pi_{M}$. All the zones remain microscopic (meaning roughly that vacant sites are dense in $\mathbb{R}$ ) until time 1 . When a match falls at some time $t \in(0,1)$ at some place $x \in \mathbb{R}$, it destroys a microscopic zone, that will be filled again after a delay $t$ (at time $2 t$ ). Hence there is a barrier at $x$ during $(t, 2 t)$. At time 1 , all the sites become occupied, except sites where there is an active barrier. Hence if a fire falls, just after time 1, it destroys a macroscopic zone, delimited by some active barriers. Such a destroyed macroscopic zone will need a delay 1 to be completely filled again. During this delay, matches produce again some barriers. And so on. See Figure 2 next page for an illustration.

The precise definition of the limit process is as follows.
Definition 2.3.1. - $A$ process $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ with values in $\mathbb{R}_{+} \times \mathcal{I} \times \mathbb{R}_{+}$such that a.s., for all $x \in \mathbb{R},\left(Z_{t}(x), H_{t}(x)\right)_{t \geq 0}$ is càdlàg, is said to be $a \operatorname{LFF}(\infty)$-process if a.s., for all $t \geq 0$, all $x \in \mathbb{R}$,

$$
\left\{\begin{array}{l}
Z_{t}(x)=\int_{0}^{t} \mathbb{1}_{\left\{Z_{s}(x)<1\right\}} \mathrm{d} s-\int_{0}^{t} \int_{\mathbb{R}} \mathbb{1}_{\left\{Z_{s-}(x)=1, y \in D_{s-}(x)\right\}} \pi_{M}(\mathrm{~d} s, \mathrm{~d} y),  \tag{2.3.1}\\
H_{t}(x)=\int_{0}^{t} Z_{s-}(x) \mathbb{1}_{\left\{Z_{s-}(x)<1\right\}} \pi_{M}(\mathrm{~d} s \times\{x\})-\int_{0}^{t} \mathbb{1}_{\left\{H_{s}(x)>0\right\}} \mathrm{d} s,
\end{array}\right.
$$

where $D_{t}(x)=\left[L_{t}(x), R_{t}(x)\right]$, with

$$
\begin{aligned}
& L_{t}(x)=\sup \left\{y \leq x: Z_{t}(y)<1 \text { or } H_{t}(y)>0\right\}, \\
& R_{t}(x)=\inf \left\{y \geq x: Z_{t}(y)<1 \text { or } H_{t}(y)>0\right\}
\end{aligned}
$$

and where $D_{t-}(x)$ is defined in the same way.
2.3.2. Formal dynamics. - Let us explain the dynamics of this process. We consider $T>0$ fixed and set $\mathcal{A}_{T}=\left\{x \in \mathbb{R}: \pi_{M}([0, T] \times\{x\})>0\right\}$. For each $t \geq 0$, $x \in \mathbb{R}, D_{t}(x)$ stands for the occupied cluster containing $x$. We call this cluster is microscopic if $D_{t}(x)=\{x\}$. We have $D_{t}(x)=D_{t}(y)$ for all $y \in D_{t}(x)$.

1. Initial condition. - We have $Z_{0}(x)=H_{0}(x)=0$ and $D_{0}(x)=\{x\}$ for all $x \in \mathbb{R}$.
2. Occupation of vacant zones. - We consider here $x \in \mathbb{R} \backslash \mathcal{A}_{T}$. Then we have $H_{t}(x)=0$ for all $t \in[0, T]$. When $Z_{t}(x)<1$, then $D_{t}(x)=\{x\}$ and $Z_{t}(x)$ stands for the local density of occupied sites around $x$ (or rather for a suitable function of this local density). Then $Z_{t}(x)$ grows linearly until it reaches 1 , as described by the first term on the RHS of the first equation in (2.3.1). When $Z_{t}(x)=1$, the cluster containing $x$ is macroscopic and is described by $D_{t}(x)$.
3. Microscopic fires. - Here we assume that $x \in \mathcal{A}_{T}$ and that the corresponding mark of $\pi_{M}$ happens at some time $t$ where $Z_{t-}(x)<1$. In such a case, the cluster containing $x$ is microscopic. Then we set $H_{t}(x)=Z_{t-}(x)$, as described by the first term on the RHS of the second equation of (2.3.1) and we leave unchanged the value of $Z_{t}(x)$. We then let $H_{t}(x)$ decrease linearly until it reaches 0 , see the second term

Figure 2. $\operatorname{LFF}(\infty)$-process in a finite box.
The marks of $\pi_{M}$ (matches) are represented as •'s. The filled zones represent zones in which $Z_{t}^{A}(x)=1$ and $H_{t}^{A}(x)=0$, that is macroscopic clusters. The plain vertical segments represent the sites where $H_{t}^{A}(x)>0$. In the rest of the space, we always have $Z_{t}^{A}(x)<1$. Until time 1 , all the clusters are microscopic. The 8 first matches fall in that zone. Thus at each of these marks, a process $H^{A}$ starts and its life-time equals the instant where it has started. For example the segment above $\left(t_{1}, x_{1}\right)$ ends at time $2 t_{1}$ : we draw a dotted segment from $\left(0, x_{1}\right)$ to $\left(t_{1}, x_{1}\right)$ and then a plain vertical segment above $\left(t_{1}, x_{1}\right)$ with the same length.

At time 1, all the clusters where there has been no mark become macroscopic and merge together. But this is limited by vertical segments. Here we have at time 1 the clusters $\left[-A, x_{6}\right],\left[x_{6}, x_{4}\right],\left[x_{4}, x_{8}\right]$, $\left[x_{8}, x_{5}\right],\left[x_{5}, x_{7}\right]$ and $\left[x_{7}, A\right]$. The segment above $\left(t_{4}, x_{4}\right)$ ends at time $2 t_{4}$ and thus at this time the clusters $\left[x_{6}, x_{4}\right]$ and $\left[x_{4}, x_{8}\right]$ merge into $\left[x_{6}, x_{8}\right]$. The 9 -th mark falls in the (macroscopic) zone $\left[x_{6}, x_{8}\right]$ and thus destroys it immediately.

This zone $\left[x_{6}, x_{8}\right]$ will become macroscopic again only at time $t_{9}+1$. A process $H^{A}$ starts at $x_{12}$ at time $t_{12}$ : we draw a dotted segment from $\left(t_{9}, x_{12}\right)$ to $\left(t_{12}, x_{12}\right)$ and then a plain vertical segment above $\left(t_{12}, x_{12}\right)$ with the same length $\left(Z_{t_{12}-}^{A}\left(x_{12}\right)=t_{12}-t_{9}\right.$ because $Z_{t_{9}}^{A}\left(x_{12}\right)$ has been set to 0 ). The segment $\left[x_{8}, x_{7}\right]$ has been destroyed at time $t_{10}$ and thus will remain microscopic until $t_{10}+1$. As a consequence, the only macroscopic clusters at time $t_{9}+1$ are $\left[-A, x_{12}\right],\left[x_{12}, x_{8}\right]$ and $\left[x_{7}, A\right]$. Then the zone $\left[x_{8}, x_{7}\right]$ becomes macroscopic (but there have been marks at $x_{13}, x_{14}$ ), so that at time $t_{10}+1$, we get the macroscopic clusters $\left[-A, x_{12}\right],\left[x_{12}, x_{14}\right],\left[x_{14}, x_{13}\right]$ and $\left[x_{13}, A\right]$. These clusters merge by pairs, at times $2 t_{12}-t_{9}, 2 t_{13}-t_{10}$ and $2 t_{14}-t_{10}$, etc.

Here we have $0 \in\left(x_{11}, x_{15}\right)$ and thus $Z_{t}^{A}(0)=t$ for $t \in[0,1], Z_{t}^{A}(0)=1$ for $t \in\left[1, t_{10}\right)$, then $Z_{t}^{A}(0)=t-t_{10}$ for $t \in\left[t_{10}, t_{10}+1\right)$, then $Z_{t}^{A}(0)=1$ for $t \in\left[t_{10}+1, t_{15}\right), \ldots$ We also see that $D_{t}^{A}(0)=\{0\}$ for $t \in[0,1), D_{t}^{A}(0)=\left[x_{8}, x_{5}\right]$ for $t \in\left[1,2 t_{5}\right), D_{t}^{A}(0)=\left[x_{8}, x_{7}\right]$ for $t \in\left[2 t_{5}, t_{10}\right)$, $D_{t}^{A}(0)=\{0\}$ for $t \in\left[t_{10}, t_{10}+1\right), D_{t}^{A}(0)=\left[x_{12}, x_{14}\right]$ for $t \in\left[t_{10}+1,2 t_{12}-t_{9}\right), D_{t}^{A}(0)=\left[-A, x_{14}\right]$ for $t \in\left[2 t_{12}-t_{9}, 2 t_{14}-t_{10}\right), \ldots$ Of course, $H_{t}^{A}(0)=0$ for all $t \geq 0$, but for example $H_{t}^{A}\left(x_{11}\right)=0$ for $t \in\left[0, t_{11}\right), H_{t}^{A}\left(x_{11}\right)=2 t_{11}-t_{10}-t$ for $t \in\left[t_{11}, 2 t_{11}-t_{10}\right)$ and then $H_{t}^{A}\left(x_{11}\right)=0$ for $t \in\left[2 t_{11}-t_{10}, \infty\right)$.
on the RHS of the second equation in (2.3.1). At all times where $H_{t}(x)>0$, the site $x$ acts like a barrier (see point 5 below).
4. Macroscopic fires. - Here we assume that $x \in \mathcal{A}_{T}$ and that the corresponding mark of $\pi_{M}$ happens at some time $t$ where $Z_{t-}(x)=1$. This means that the cluster containing $x$ is macroscopic and thus this mark destroys the whole component $D_{t-}(x)$, that is for all $y \in D_{t-}(x)$, we set $D_{t}(y)=\{y\}, Z_{t}(y)=0$. This is described by the second term on the RHS of the first equation in (2.3.1).
5. Clusters. - Finally the definition of the clusters $\left(D_{t}(x)\right)_{x \in \mathbb{R}}$ becomes more clear: these clusters are delimited by zones with local density smaller than 1 (i.e. $Z_{t}(y)<1$ ) or by sites where a microscopic fire has (recently) started (i.e. $H_{t}(y)>0$ ).

For $A>0$, we call $\left(Z_{t}^{A}(x), D_{t}^{A}(x), H_{t}^{A}(x)\right)_{t \geq 0, x \in[-A, A]}$ the finite box version of the $\operatorname{LFF}(\infty)$-process: it has the same dynamics as the true $\operatorname{LFF}(\infty)$-process, but we restrict the space of tree positions to $x \in[-A, A]$. See section 3.10 for a more precise definition. On Figure 2, a typical path of this finite box $\operatorname{LFF}(\infty)$-process is discussed. See also Algorithm 3.6.3 (with the function $F_{S}(z, v)=z$ ).
2.3.3. Well-posedness. - The existence and uniqueness of the $\operatorname{LFF}(\infty)$-process has been proved in [15, Theorem 3]. We will provide here a simpler proof, which also works for the case where $\beta=B S$.

Theorem 2.3.2. - For any Poisson measure $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)$ on $[0, \infty) \times \mathbb{R}$ with intensity measure $\mathrm{d} t \mathrm{~d} x$, there a.s. exists a unique $\operatorname{LFF}(\infty)$-process. Furthermore, it can be constructed graphically and its restriction to any finite box $[0, T] \times[-n, n]$ can be perfectly simulated.

The $\operatorname{LFF}(\infty)$-process $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ is furthermore Markov, since it solves a well-posed time homogeneous Poisson-driven S.D.E.
2.3.4. The convergence result. - Recall subsection 2.1.5.

Theorem 2.3.3. - Assume $\left(H_{M}\right)$ and $\left(H_{S}(\infty)\right)$. Recall that $\boldsymbol{a}_{\lambda}, \boldsymbol{n}_{\lambda}$ and $\boldsymbol{m}_{\lambda}$ were defined in (2.2.1)(2.2.2)-(2.2.4). Consider, for each $\lambda \in(0,1]$, the process $\left(Z_{t}^{\lambda}(x), D_{t}^{\lambda}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ associated with the $\mathrm{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process, see Definition 2.1.3, (2.2.3) and (2.2.5). Consider also the $\operatorname{LFF}(\infty)$-process $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$.
(a) For any $T>0$, any finite subset $\left\{x_{1}, \ldots, x_{p}\right\} \subset \mathbb{R}$,

$$
\left(Z_{t}^{\lambda}\left(x_{i}\right), D_{t}^{\lambda}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p}
$$

goes in law to $\left(Z_{t}\left(x_{i}\right), D_{t}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p}$, in $\mathbb{D}([0, T], \mathbb{R} \times \mathcal{I} \cup\{\varnothing\})^{p}$, as $\lambda$ tends to 0 . Here $\mathbb{D}([0, \infty), \mathbb{R} \times \mathcal{I} \cup\{\varnothing\})$ is endowed with the distance $\boldsymbol{d}_{T}$.
(b) For any finite subset $\left\{\left(t_{1}, x_{1}\right), \ldots,\left(t_{p}, x_{p}\right)\right\} \subset[0, \infty) \times \mathbb{R}$, with $t_{k} \neq 1$ for $k=1, \ldots, p,\left(Z_{t_{i}}^{\lambda}\left(x_{i}\right), D_{t_{i}}^{\lambda}\left(x_{i}\right)\right)_{i=1, \ldots, p}$ goes in law to $\left(Z_{t_{i}}\left(x_{i}\right), D_{t_{i}}\left(x_{i}\right)\right)_{i=1, \ldots, p}$ in $(\mathbb{R} \times \mathcal{I} \cup\{\varnothing\})^{p}$. Here $\mathcal{I} \cup\{\varnothing\}$ is endowed with $\boldsymbol{\delta}$.
(c) Recall notation 2.1.5 (ii). For all $t>0$,

$$
\left(\frac{\psi_{S}\left(1-1 /\left|C\left(\eta_{\boldsymbol{a}_{\lambda} t}^{\lambda}, 0\right)\right|\right)}{\boldsymbol{a}_{\lambda}} \mathbb{1}_{\left\{\left|C\left(\eta \hat{\boldsymbol{a}}_{\lambda^{\star} t}, 0\right)\right| \geq 1\right\}}\right) \wedge 1
$$

goes in law to $Z_{t}(0)$ as $\lambda \rightarrow 0$.
Point (c) will allow us to check some estimates on the cluster-size distribution. Since we deal with finite-dimensional marginals in space, it is quite clear that the process $H$ does not appear in the limit, since for each $x \in \mathbb{R}$, a.s., for all $t \geq 0$, $H_{t}(x)=0$. (Of course, it is false that a.s., for all $x \in \mathbb{R}$, all $t \geq 0, H_{t}(x)=0$ ).

We cannot guarantee the convergence in law of $D_{t}^{\lambda}(0)$ to $D_{t}(0)$ at time $t=1$. This is due to the fact that when neglecting fires, the probability that a macroscopic zone is completely occupied at time $\boldsymbol{a}_{\lambda} t$, tends to 1 if $t>1$, but to a nontrivial value if $t=1$.

For example, in the absence of fires, a zone with length $\boldsymbol{n}_{\lambda}$ is completely occupied at time $\boldsymbol{a}_{\lambda} t$ with probability $\nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda} t\right)\right)^{\boldsymbol{n}_{\lambda}} \simeq \exp \left(-\boldsymbol{n}_{\lambda} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)\right.$, which tends to 1 if $t>1$ and to $1 / e$ if $t=1$.

We believe that this is really not important and we decided to keep this definition of the $\operatorname{LFF}(\infty)$-process despite this light defect.
2.3.5. Heuristic arguments. - Let us explain here roughly the reasons why Theorem 2.3.3 holds true. We consider, for $\lambda>0$ very small, a $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ and the associated processes $\left(Z_{t}^{\lambda}(x), D_{t}^{\lambda}(x)\right)_{t \geq 0, x \in \mathbb{R}}$.
0. Matches. - The times and positions at which matches fall will tend, in our scales, to the marks of a Poisson measure with intensity measure 1. A hint for this is the following. Consider e.g. the domain $[0, T] \times[0,1]$, which corresponds to $\left[0, \boldsymbol{a}_{\lambda} T\right] \times \llbracket 0, \boldsymbol{n}_{\lambda} \rrbracket$. The probability that two matches fall on the same site during $\left[0, \boldsymbol{a}_{\lambda} T\right]$ is very small. Thus the number of matches falling in $\left[0, \boldsymbol{a}_{\lambda} T\right] \times \llbracket 0, \boldsymbol{n}_{\lambda} \rrbracket$ has approximately a Binomial distribution with parameters $\boldsymbol{n}_{\lambda}$ and $\nu_{M}\left(\left[0, \boldsymbol{a}_{\lambda} T\right]\right)$. Since

$$
\boldsymbol{n}_{\lambda} \nu_{M}^{\lambda}\left(\left[0, \boldsymbol{a}_{\lambda} T\right]\right) \simeq \frac{1}{\lambda \boldsymbol{a}_{\lambda}}\left[\int_{0}^{\boldsymbol{a}_{\lambda} T} \lambda \mu_{M}^{1}\left(\left(\lambda \boldsymbol{a}_{\lambda} t, \infty\right)\right) \mathrm{d} t\right] \longrightarrow T
$$

as $\lambda \rightarrow 0$, the asymptotic number of matches falling in $[0, T] \times[0,1]$ should have a Poisson distribution with parameter $T$.

1. Initial condition. - For all $x \in \mathbb{R},\left(Z_{0}^{\lambda}(x), D_{0}^{\lambda}(x)\right)=(0, \varnothing) \simeq(0,\{x\})$ (recall that $\left.\psi_{S}(0)=0\right)$.
2. Occupation of vacant zones. - Assume that a zone $[a, b]$ becomes completely vacant at some time $t$ (because it has been destroyed by a fire).
(i) For $s \in[0,1)$ and if no fire starts on $[a, b]$ during $[t, t+s]$, we have

$$
D_{t+s}^{\lambda}(x) \simeq\left[x \pm 1 /\left(\boldsymbol{n}_{\lambda} \nu_{S}\left(\boldsymbol{a}_{\lambda} s, \infty\right)\right)\right] \simeq\{x\}
$$

and $Z_{t+s}^{\lambda}(x) \simeq s$ for all $x \in[a, b]$.

Indeed, $D_{t+s}^{\lambda}(x) \simeq\left[x-X / \boldsymbol{n}_{\lambda}, x+Y / \boldsymbol{n}_{\lambda}\right]$, where $X$ and $Y$ are approximately geometric random variables with parameter $\nu_{S}\left(\left(a_{\lambda} s, \infty\right)\right)$. (Recall that for any $t \geq 0$ and for any site, $\nu_{S}$ is the law of the time we have to wait until the next seed falls). Thus

$$
D_{t+s}^{\lambda}(x) \simeq\left[x \pm 1 /\left(\boldsymbol{n}_{\lambda} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} s, \infty\right)\right)\right] \simeq\{x\}\right.
$$

due to $\left(H_{S}(\infty)\right)$, since $\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} s, \infty\right)\right) \gg \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right) \simeq 1 / \boldsymbol{n}_{\lambda}$. For the same reasons,

$$
K_{t+s}^{\lambda}(x) \simeq \nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda} s\right)\right)
$$

whence $Z_{t+s}^{\lambda}(x) \simeq s$.
(ii) If no fire starts on $[a, b]$ during $[t, t+1]$, then $Z_{t+1}^{\lambda}(x) \simeq 1$ and all the sites in $[a, b]$ are occupied (with very high probability) just after time $t+1$.
Indeed, we have $(b-a) \boldsymbol{n}_{\lambda}$ sites and each of them is occupied at time $t+1+\varepsilon$ with approximate probability $\nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda}(1+\varepsilon)\right]\right)$, so that all of them are occupied with approximate probability

$$
\left(\nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda}(1+\varepsilon)\right)\right)\right)^{(b-a) \boldsymbol{n}_{\lambda}} \simeq \exp \left(-(b-a) \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}(1+\varepsilon), \infty\right)\right) / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)\right)
$$

which tends to 1 as $\lambda \rightarrow 0$ for any $\varepsilon>0$ by $\left(H_{S}(\infty)\right)$.
3. Microscopic fires. - Assume that a fire starts at some place $x$ at some time $t$, with $Z_{t-}^{\lambda}(x)=z \in(0,1)$. Then the possible clusters on the left and right of $x$ cannot be connected during (approximately) $[t, t+z]$, but can be connected after (approximately) $t+z$.

Indeed, the match falls in a zone with approximate density $\nu_{S}\left(\left(0, a_{\lambda} z\right)\right)$, so that it should destroy a zone $A$ of approximate length $1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} z, \infty\right)\right) \ll \boldsymbol{n}_{\lambda}$. The probability that a fire starts again in $A$ after $t$ is very small. Thus the probability that $A$ is completely occupied at time $t+s$ is approximately

$$
\left(\nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda} s\right]\right)\right)^{1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} z, \infty\right)\right)} \simeq \exp \left(-\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} s, \infty\right)\right) / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} z, \infty\right)\right)\right)
$$

When $\lambda \rightarrow 0$, this quantity tends to 0 if $s<z$ and to 1 if $s>z$ thanks to $\left(H_{S}(\infty)\right)$.
4. Macroscopic fires. - Assume now that a fire starts at some place $x$, at some time $t$ and that $Z_{t-}^{\lambda}(x) \simeq 1$, so that $D_{t-}^{\lambda}(x)$ is macroscopic (that is its length is of order 1 in our scales, or of order $\boldsymbol{n}_{\lambda}$ in the original process). This will thus make vacant the zone $D_{t-}^{\lambda}(x)$. Such a (macroscopic) zone needs a time of order 1 to be completely occupied, see point 2 .
5. Clusters. - For $t \geq 0, x \in \mathbb{R}$, the cluster $D_{t}^{\lambda}(x)$ resembles

$$
\left[x \pm 1 /\left(\boldsymbol{n}_{\lambda} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} z, \infty\right)\right)\right)\right] \simeq\{x\}
$$

if $Z_{t}^{\lambda}(x)=z \in(0,1)$. We then say that $x$ is microscopic. Macroscopic clusters are delimited either by microscopic zones, or by sites where there has been recently a microscopic fire.

Even if the above arguments are (hopefully) quite convincing, the rigorous proof is long and tedious. The main idea is that even if each isolated event is easily treated (for example, the fact that a vacant macroscopic zone needs a delay 1 to be completely filled again relies on an immediate computation; estimating the delay needed to fill again the zone destroyed by a microscopic fire is not difficult, etc.), it is quite hard to follow the process during an arbitrary large time interval. Indeed, we have to check that the small errors due to one such event do not become large errors after some time. For example, if a macroscopic zone is not filled at time 1, but slightly after (say at time $t_{0}>1$ ), this could reduce consequently the impact of a match falling in this zone between 1 and $t_{0}$, etc. The main ideas of the proof are however quite simple and really rely on the above heuristic arguments.
2.3.6. Cluster-size distribution. - We will deduce from Theorem 2.3.3 the following estimates on the cluster-size distribution.

Corollary 2.3.4. - Assume $\left(H_{M}\right)$ and $\left(H_{S}(\infty)\right)$. Recall that $\boldsymbol{a}_{\lambda}$ and $\boldsymbol{n}_{\lambda}$ were defined in (2.2.1) and (2.2.2). Let $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ be $a \operatorname{LFF}(\infty)$-process. For each $\lambda \in(0,1]$, let $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ be a $\mathrm{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process.
(i) For some $0<c_{1}<c_{2}$, for all $t \geq \frac{5}{2}$, all $0<a<b<1$,

$$
\begin{array}{r}
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\left|C\left(\eta_{\boldsymbol{a}_{\lambda} t}^{\lambda}, 0\right)\right| \in\left[1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} a, \infty\right)\right), 1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} b, \infty\right)\right)\right]\right) \\
=\operatorname{Pr}\left(Z_{t}(0) \in[a, b]\right) \in\left[c_{1}(b-a), c_{2}(b-a)\right] .
\end{array}
$$

(ii) For some $0<c_{1}<c_{2}$ and $0<\kappa_{1}<\kappa_{2}$, for all $t \geq \frac{3}{2}$, all $B>0$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\left|C\left(\eta_{a_{\lambda} t}^{\lambda}, 0\right)\right| \geq B \boldsymbol{n}_{\lambda}\right)=\operatorname{Pr}\left(\left|D_{t}(0)\right| \geq B\right) \in\left[c_{1} \mathrm{e}^{-\kappa_{2} B}, c_{2} \mathrm{e}^{-\kappa_{1} B}\right] .
$$

This results shows that there is a phase transition around the critical size $\boldsymbol{n}_{\lambda}$ : the cluster-size distribution changes of shape at $\boldsymbol{n}_{\lambda}$.

Consider the case of Example 2, where $\mu_{S}((t, \infty)) \stackrel{\infty}{\sim} \mathrm{e}^{-t^{\alpha}}$. Then

$$
\boldsymbol{a}_{\lambda} \sim(\log (1 / \lambda))^{1 / \alpha} \quad \text { and } \quad \boldsymbol{n}_{\lambda} \sim 1 /\left[\lambda(\log (1 / \lambda))^{1 / \alpha}\right] .
$$

Very roughly, Corollary 2.3 .4 proves that when $\lambda \rightarrow 0$, the law of $\left|C\left(\eta^{\lambda}, 0\right)\right|$, for large times, resembles

$$
\frac{[\log (1+x)]^{1 / \alpha-1}}{(1+x)[\log (1 / \lambda)]^{1 / \alpha}} \mathbb{1}_{\left\{x \in\left[0, \boldsymbol{n}_{\lambda}\right]\right\}} \mathrm{d} x+\left(1 / \boldsymbol{n}_{\lambda}\right) \mathrm{e}^{-x / \boldsymbol{n}_{\lambda}} \mathbb{1}_{\{x \geq 0\}} \mathrm{d} x .
$$

The first term corresponds approximately to the law of $1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} U, \infty\right)\right)$, for $U$ uniformly distributed on $[0,1]$ and the second term is an exponential law with mean $\boldsymbol{n}_{\lambda}$.

The main idea is that two types of clusters are present: macroscopic clusters, of which the size is of order $\boldsymbol{n}_{\lambda} \sim \lambda^{-1}[\log (1 / \lambda)]^{-1 / \alpha}$, with an exponential-like distribution; and microscopic clusters, of which the size is smaller than $\boldsymbol{n}_{\lambda}$, with a law with shape $\log (1+x)^{1 / \alpha-1} /(1+x)$.

### 2.4. Main result in the case $\beta=B S$

This case is slightly more complicated than the case $\beta=\infty$. The limit process is essentially the same, except that the height of the barriers (vertical segments in Figure 2) are more random.
2.4.1. Law of the heights of the barriers. - Start at time 0 with all sites vacant. Let $u \in(0,1)$. Assume that a match falls at site 0 at time $T_{S} u$ and neglect all other fires. Call $\Theta_{u}$ the time needed for the destroyed zone to be completely regenerated and $\theta_{u}$ the law of $\Theta_{u} / T_{S}$. Clearly, $\theta_{u}$ is supported by $[0,1]$. We will show in Lemma 3.9.1 below that $\theta_{u}$ can be defined as follows.

Definition 2.4.1. - Assume $\left(H_{S}(B S)\right.$ ). For $t, s \in[0, \infty)$, we denote by

$$
g_{S}(t, s)=\operatorname{Pr}\left[N_{T_{S} t}^{S}>0, N_{T_{S}(t+s)}^{S}>N_{T_{S} t}^{S}\right]
$$

where $\left(N_{t}^{S}\right)_{t \geq 0}$ is a $\operatorname{SR}\left(\mu_{S}\right)$-process. For $u \in(0,1)$, we consider the probability measure $\theta_{u}$ on $[0,1]$ defined by

$$
\forall h \in[0,1], \quad \theta_{u}([0, h])=\nu_{S}\left(\left(T_{S} u, T_{S}\right)\right)+\left(\frac{\nu_{S}\left(\left(T_{S} u, T_{S}\right)\right)}{1-g_{S}(u, h)}\right)^{2} g_{S}(u, h)
$$

Finally, we consider a function

$$
F_{S}:[0,1] \times[0,1] \longrightarrow[0,1]
$$

such that for each $u \in[0,1]$ and for $V$ a uniformly distributed random variable on $[0,1]$, the law of $F_{S}(u, V)$ is $\theta_{u}$. We can choose $F_{S}$ in such a way that for each $u \in[0,1], v \mapsto F_{S}(u, v)$ is nondecreasing.

Let $u \in[0,1]$ be fixed. Since $\mu_{S}\left(\left[0, T_{S}\right]\right)=1$, there holds $g_{S}(u, 1)=\nu_{S}\left(\left[0, T_{S} u\right]\right)$, whence $\theta_{u}([0,1])=1$. To check that $h \mapsto \theta_{u}([0, h])$ is nondecreasing, it suffices to observe that $h \mapsto g(u, h)$ is nondecreasing. Notice that $\theta_{u}(\{0\})=\nu_{S}\left(\left(T_{S} u, T_{S}\right)\right)$ : this corresponds to the situation where nothing has been destroyed because the match has fallen on an empty site. For $F_{S}(u,$.$) , one can e.g. use the generalized inverse function$ of $\theta_{u}([0,]$.$) .$
2.4.2. Definition of the limit process. - Let $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)$ be a Poisson measure on $[0, \infty) \times \mathbb{R}$ with intensity measure $\mathrm{d} t \mathrm{~d} x$, whose marks correspond to matches. We also consider an i.i.d. sequence $\left(V_{k}\right)_{k \geq 1}$ of uniformly distributed random variables on $[0,1]$, independent of $\pi_{M}$. If

$$
\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)=\sum_{k \geq 1} \delta_{\left(T_{k}, X_{k}\right)}
$$

we (abusively) write

$$
\pi_{M}(\mathrm{~d} t, \mathrm{~d} x, \mathrm{~d} v)=\sum_{k \geq 1} \delta_{\left(T_{k}, X_{k}, V_{k}\right)}
$$

Observe that $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x, \mathrm{~d} v)$ is a Poisson measure on $[0, \infty) \times \mathbb{R} \times[0,1]$ with intensity measure $\mathrm{d} t \mathrm{~d} x \mathrm{~d} v$.

Definition 2.4.2. - A process $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ with values in $\mathbb{R}_{+} \times$ $\mathcal{I} \times \mathbb{R}_{+}$such that a.s., for all $x \in \mathbb{R},\left(Z_{t}(x), H_{t}(x)\right)_{t \geq 0}$ is càdlàg, is said to be a $\operatorname{LFF}(B S)$-process if a.s., for all $t \geq 0$, all $x \in \mathbb{R}$,

$$
\begin{align*}
& \text { (2.4.1) }\left\{\begin{array}{l}
Z_{t}(x)=\int_{0}^{t} \mathbb{1}_{\left\{Z_{s}(x)<1\right\}} \mathrm{d} s-\int_{0}^{t} \int_{\mathbb{R}} \mathbb{1}_{\left\{Z_{s-}(x)=1, y \in D_{s-}(x)\right\}} \pi_{M}(\mathrm{~d} s, \mathrm{~d} y), \\
H_{t}(x)=\int_{0}^{t} \int_{0}^{1} F_{S}\left(Z_{s-}(x), v\right) \mathbb{1}_{\left\{Z_{s-}(x)<1\right\}} \pi_{M}(\mathrm{~d} s \times\{x\} \times \mathrm{d} v) \\
\text { where } D_{t}(x)=\left[L_{t}(x), R_{t}(x)\right], \text { with }
\end{array}\right.  \tag{2.4.1}\\
& \quad-\int_{0}^{t} \mathbb{1}_{\left\{H_{s}(x)>0\right\}} \mathrm{d} s,
\end{align*}
$$

$$
\begin{aligned}
& L_{t}(x)=\sup \left\{y \leq x: Z_{t}(y)<1 \text { or } H_{t}(y)>0\right\} \\
& R_{t}(x)=\inf \left\{y \geq x: Z_{t}(y)<1 \text { or } H_{t}(y)>0\right\}
\end{aligned}
$$

and where $D_{t-}(x)$ is defined in the same way.
The difference with the $\operatorname{LFF}(\infty)$-process is that when a match falls at $(t, x)$ with $Z_{t-}(x)<1$, we choose $H_{t}(x)$ according to the law $\theta_{Z_{t-}(x)}$, instead of simply setting $H_{t}(x)=Z_{t-}(x)$.
2.4.3. Formal dynamics. - Let us explain the dynamics of this process. We consider $T>0$ fixed and set

$$
\mathcal{A}_{T}=\left\{x \in \mathbb{R}: \pi_{M}([0, T] \times\{x\})>0\right\} .
$$

For each $t \geq 0, x \in \mathbb{R}, D_{t}(x)$ stands for the occupied cluster containing $x$. We call this cluster is microscopic if $D_{t}(x)=\{x\}$. We have $D_{t}(x)=D_{t}(y)$ for all $y \in D_{t}(x)$.

1. Initial condition. - We have, for all $x \in \mathbb{R}$

$$
Z_{0}(x)=H_{0}(x)=0 \quad \text { and } \quad D_{0}(x)=\{x\} .
$$

2. Occupation of vacant zones. - We consider here $x \in \mathbb{R} \backslash \mathcal{A}_{T}$. Then we have $H_{t}(x)=0$ for all $t \in[0, T]$. When $Z_{t}(x)<1$, then $D_{t}(x)=\{x\}$ and $Z_{t}(x)$ stands for the local density of occupied sites around $x$ (or rather for a suitable function of this density) Then $Z_{t}(x)$ grows linearly until it reaches 1 , as described by the first term on the RHS of the first equation in (2.4.1). When $Z_{t}(x)=1$, the cluster containing $x$ is macroscopic and is described by $D_{t}(x)$.
3. Microscopic fires. - Here we assume that $x \in \mathcal{A}_{T}$ and that the corresponding mark of $\pi_{M}$ happens at some time $t$ where $Z_{t-}(x)<1$. In such a case, the cluster containing $x$ is microscopic. Then we set $H_{t}(x)=F_{S}\left(Z_{t-}(x), V\right)$, for some uniformly distributed $V$ on $[0,1]$ as described by the first term on the RHS of the second equation of (2.4.1). We then let $H_{t}(x)$ decrease linearly until it reaches 0 , see the second term on the RHS of the second equation in (2.4.1). At all times where $H_{s}(x)>0$, the site $x$

Figure 3. $\operatorname{LFF}(B S)$-process in a finite box.
The marks of $\pi_{M}$ (matches) are represented as •'s. The filled zones represent zones in which $Z_{t}^{A}(x)=1$ and $H_{t}^{A}(x)=0$, that is macroscopic clusters. The plain vertical segments represent the sites where $H_{t}^{A}(x)>0$. In the rest of the space, we always have $Z_{t}^{A}(x)<1$.
acts like a barrier (see point 5 below). All this means that at $x$, there is a barrier during $\left[t, t+H_{t}(x)\right)$, where $H_{t}(x)$ is chosen at random, according to the law $\theta_{Z_{t-}(x)}$.
4. Macroscopic fires. - Here we assume that $x \in \mathcal{A}_{T}$ and that the corresponding mark of $\pi_{M}$ happens at some time $t$ where $Z_{t-}(x)=1$. This means that the cluster containing $x$ is macroscopic and thus this mark destroys the whole component $D_{t-}(x)$, that is for all $y \in D_{t-}(x)$, we set $D_{t}(y)=\{y\}, Z_{t}(y)=0$. This is described by the second term on the RHS of the first equation in (2.4.1).
5. Clusters. - Finally the clusters $\left(D_{t}(x)\right)_{x \in \mathbb{R}}$ are delimited by zones with density smaller than 1 (i.e. $Z_{t}(y)<1$ ) or by sites where a microscopic fire has (recently) started (i.e. $\left.H_{t}(y)>0\right)$.

A typical path of a finite-box version $\left(Z_{t}^{A}(x), D_{t}^{A}(x), H_{t}^{A}(x)\right)_{t \geq 0, x \in[-A, A]}$ of the $\operatorname{LFF}(B S)$-process is discussed on Figure 3. It is very similar to Figure 2: the only difference is that each time there is a bullet falling at some $(t, x)$ in a white zone, the height of the segment above $(t, x)$ is chosen at random, according to the law $\theta_{Z_{t-}(x)}$. And $Z_{t-}(x)$ equals the time passed since $x$ was involved in a macroscopic fire (the case $\operatorname{LFF}(\infty)$ corresponds to the law $\theta_{z}=\delta_{z}$ ). See also Algorithm 3.6.3 below.
2.4.4. Well-posedness. - We will prove the following result.

Theorem 2.4.3. - For any Poisson measure $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x, \mathrm{~d} v)$ on $[0, \infty) \times \mathbb{R} \times[0,1]$ with intensity measure $\mathrm{d} t \mathrm{~d} x \mathrm{~d} v$ (and for $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)=\int_{v \in[0,1]} \pi_{M}(\mathrm{~d} t, \mathrm{~d} x, \mathrm{~d} v)$ ), there a.s. exists a unique $\operatorname{LFF}(B S)$-process. Furthermore, it can be constructed graphically and its restriction to any finite box $[0, T] \times[-n, n]$ can be perfectly simulated.

The $\operatorname{LFF}(B S)$-process $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ is furthermore Markov, since it solves a well-posed time homogeneous Poisson-driven S.D.E.
2.4.5. The convergence result. - We are now in a position to state the main result of this section. Recall subsection 2.1.5.

Theorem 2.4.4. - Assume $\left(H_{M}\right)$ and $\left(H_{S}(B S)\right)$. Recall that $\boldsymbol{a}_{\lambda}=T_{S}, \boldsymbol{n}_{\lambda}=$ $\left\lfloor 1 /\left(\lambda T_{S}\right)\right\rfloor$ and let $\boldsymbol{m}_{\lambda}$ satisfy (2.2.4). Consider, for each $\lambda \in(0,1]$, the process $\left(D_{t}^{\lambda}(x), Z_{t}^{\lambda}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ associated with the $\mathrm{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$, see Definition 2.1.3, (2.2.3) and (2.2.5). Consider also the $\operatorname{LFF}(B S)$-process

$$
\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}^{\prime}}
$$

(a) For any $T>0$, any finite subset $\left\{x_{1}, \ldots, x_{p}\right\} \subset \mathbb{R},\left(Z_{t}^{\lambda}\left(x_{i}\right), D_{t}^{\lambda}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p}$ goes in law to $\left(Z_{t}\left(x_{i}\right), D_{t}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p}$, in $\mathbb{D}([0, T], \mathbb{R} \times \mathcal{I} \cup\{\varnothing\})^{p}$, as $\lambda$ tends to 0 . Here $\mathbb{D}([0, \infty), \mathbb{R} \times \mathcal{I} \cup\{\varnothing\})$ is endowed with the distance $\boldsymbol{d}_{T}$.
(b) For any finite subset $\left\{\left(t_{1}, x_{1}\right), \ldots,\left(t_{p}, x_{p}\right)\right\} \subset[0, \infty) \times \mathbb{R},\left(Z_{t_{i}}^{\lambda}\left(x_{i}\right), D_{t_{i}}^{\lambda}\left(x_{i}\right)\right)_{i=1, \ldots, p}$ goes in law to $\left(Z_{t_{i}}\left(x_{i}\right), D_{t_{i}}\left(x_{i}\right)\right)_{i=1, \ldots, p}$ in $(\mathbb{R} \times \mathcal{I} \cup\{\varnothing\})^{p}$. Here $\mathcal{I} \cup\{\varnothing\}$ is endowed with $\boldsymbol{\delta}$.
(c) For any $t \geq 0$, any $k \in \mathbb{N}$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|C\left(\eta_{T_{S} t}^{\lambda}, 0\right)\right|=k\right]=\mathbb{E}\left[q_{k}\left(Z_{t}(0)\right)\right]
$$

where, for $z \in[0,1]$,

$$
\left\{\begin{array}{l}
q_{0}(z)=\nu_{S}\left(\left(z T_{S}, T_{S}\right)\right)  \tag{2.4.2}\\
q_{k}(z)=k\left[\nu_{S}\left(\left(z T_{S}, T_{S}\right)\right)\right]^{2}\left[\nu_{S}\left(\left(0, z T_{S}\right)\right)\right]^{k} \quad \text { if } k \geq 1
\end{array}\right.
$$

Here we have no problem with $t=1$ : for the discrete process (in the absence of fires), all the sites are occupied at time $T_{S}$ (which corresponds to time 1 after normalization). Point (c) will be useful to prove some estimates about the clustersize distribution. Observe that for $z \in(0,1), q_{k}(z)$ is the probability that the cluster around 0 has the size $k$ at time $T_{S} z$, in the absence of fires, if seeds fall according to i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes.
2.4.6. Heuristic arguments. - Let us explain roughly the reasons why Theorem 2.4.4 holds true. We consider a $\mathrm{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ and the corresponding processes $\left(Z_{t}^{\lambda}(x), D_{t}^{\lambda}(x)\right)_{t \geq 0, x \in \mathbb{R}}$. We assume below that $\lambda$ is very small.
0. Matches. - As in the case $\beta=\infty$, the times and positions at which matches fall will tend, in our scales, to the marks of a Poisson measure with intensity measure 1.

1. Initial condition. - We have, for all $x \in \mathbb{R},\left(Z_{0}^{\lambda}(x), D_{0}^{\lambda}(x)\right)=(0, \varnothing) \simeq(0,\{x\})$.
2. Occupation of vacant zones. - Assume that a zone $[a, b]$ becomes completely vacant at some time $t$ (because it has been destroyed by a fire).
(i) For $s \in\left[0,1\right.$ ) and if no fire starts on $[a, b]$ during $[t, t+s]$ (or $\left[T_{S} t, T_{S}(t+s)\right]$ in the original scales) the density of vacant sites in $[a, b]$ at time $t+s$ should clearly resemble $\nu_{S}\left(\left(0, T_{S} s\right)\right)$. Hence for $x \in[a, b], Z_{t}^{\lambda}(x) \simeq \psi_{S}\left(\nu_{S}\left(\left(0, T_{S} s\right)\right)\right)=s$ and $D_{t+s}^{\lambda}(x) \simeq\{x\}$.
(ii) If no fire starts on $[a, b]$ during $[t, t+1]$ (or $\left[T_{S} t, T_{S}(t+1)\right]$ in the original scales), then all the sites of $[a, b]$ become occupied at time $t+1$ (recall that $\left.\nu_{S}\left(\left(0, T_{S}\right]\right)=1\right)$.
3. Microscopic fires. - Assume that a fire starts at some place $x$ at some time $t$, with $Z_{t-}^{\lambda}(x)=z \in(0,1)$. Then the possible clusters on the left and right of $x$ cannot be connected during (approximately) $\left[t, t+\Theta_{z} T_{S}\right]$, but can be connected after (approximately) $t+\Theta_{z} T_{S}$, where $\Theta_{z}$ follows approximately the law $\theta_{z}$. Indeed, $\theta_{z}$ is designed for that: consider a zone where the density of occupied sites is $z$ and assume that the sites are exchangeable in this zone. Pick at random a cluster in this zone. The law of its size depends on $z$. Then $\theta_{z}$ is the law of the time needed for a seed to fall on each sites of this cluster (divided by $T_{S}$ ).
4. Macroscopic fires. - Assume now that a fire starts at some place $x$, at some time $t$ and that $Z_{t-}^{\lambda}(x) \simeq 1$, so that $D_{t-}^{\lambda}(x)$ is macroscopic (that is its length is of order 1 in our scales, or of order $\boldsymbol{n}_{\lambda}$ in the original process). This will thus make vacant the zone $D_{t-}^{\lambda}(x)$. Such a (macroscopic) zone needs a time of order 1 to be completely occupied, see point 2 .
5. Clusters. - For $t \geq 0, x \in \mathbb{R}$, there are some vacant sites in the neighborhood of $x$ if $Z_{t}^{\lambda}(x)<1$ (then we say that $x$ is microscopic), or if there has been (recently) a microscopic fire at $x$ (see point 3). Now macroscopic clusters are delimited either by microscopic zones, or by sites where there has been recently a microscopic fire.

To transform these heuristic arguments into a rigorous proof, we have essentially the same difficulties as when $\beta=\infty$ (see subsection 2.3.5): each isolated event is easily treated, but it is quite hard to put everything together.
2.4.7. Cluster-size distribution. - We will deduce from Theorem 2.4.4 the following estimates on the cluster-size distribution.

Corollary 2.4.5. - Assume $\left(H_{M}\right)$ and $\left(H_{S}(B S)\right)$. Recall that $\boldsymbol{a}_{\lambda}$ and $\boldsymbol{n}_{\lambda}$ were defined in (2.2.1) and (2.2.2). Let $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ be a $\operatorname{LFF}(B S)$-process. For each $\lambda \in(0,1]$, let $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ be $a \operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process.
(i) For some $0<c_{1}<c_{2}$, for all $t \geq \frac{5}{2}$, all $k \in\{0,1, \ldots\}$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\left|C\left(\eta_{T_{S} t}^{\lambda}, 0\right)\right|=k\right) \in\left[c_{1} q_{k}, c_{2} q_{k}\right]
$$

where, for $k \geq 1$

$$
q_{0}=\int_{0}^{1} \nu_{S}\left(\left(T_{S} z, T_{S}\right)\right) \mathrm{d} z \quad \text { and } \quad q_{k}=k \int_{0}^{1}\left[\nu_{S}\left(\left(T_{S} z, T_{S}\right)\right)\right]^{2}\left[\nu_{S}\left(\left(0, T_{S} z\right)\right)\right]^{k} \mathrm{~d} z
$$

(ii) For some $0<c_{1}<c_{2}$ and $0<\kappa_{1}<\kappa_{2}$, for all $t \geq \frac{3}{2}$, all $B>0$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\left|C\left(\eta_{T_{S} t}^{\lambda}, 0\right)\right| \geq B \boldsymbol{n}_{\lambda}\right)=\operatorname{Pr}\left(\left|D_{t}(0)\right| \geq B\right) \in\left[c_{1} \mathrm{e}^{-\kappa_{2} B}, c_{2} \mathrm{e}^{-\kappa_{1} B}\right]
$$

Consider the case of Example 1, where $\mu_{S}=\delta_{1}, T_{S}=1$ and $\nu_{S}(\mathrm{~d} t)=\mathbb{1}_{[0,1]}(t) \mathrm{d} t$. Then $\boldsymbol{n}_{\lambda} \sim 1 / \lambda$ and one can check that $q_{0}=\frac{1}{2}$ and $q_{k}=2 k /[(k+1)(k+2)(k+3)]$ for $k \geq 1$.

Corollary 2.4.5 shows the presence of two regimes: for $\lambda>0$ very small, there are some finite (uniformly in $\lambda$ ) clusters, as described in point (i) and some clusters of order $1 / \lambda$, as described in point (ii). Roughly, for $\lambda>0$ very small, the cluster-size distribution resembles, for large times,

$$
\sum_{k \geq 0} q_{k} \delta_{k}(\mathrm{~d} x)+\lambda \mathrm{e}^{-\lambda x} \mathbb{1}_{\{x \geq 0\}} \mathrm{d} x
$$

### 2.5. Main results when $\beta \in(0, \infty)$

2.5.1. Definition of the limit process. - Surprisingly, the limit process in this case is more natural than in the previous cases, in the sense that there are only macroscopic clusters and thus no microscopic fires: heavy tails can sometimes produce natural objects. This is due to the fact that for $\beta<\infty$, the scale space $\boldsymbol{n}_{\lambda}$ is correct for all times. We describe the limit forest fire process by a graphical construction. The limit forest fire process $\left(Y_{t}(x)\right)_{x \in \mathbb{R}, t \geq 1}$ will take its values in $\{0,1\}$. In some sense, $Y_{t}(x)=0$ means that there is no tree at $x$ at time $t$.

For $(Y(x))_{x \in \mathbb{R}}$ with values in $\{0,1\}$, we define the occupied component around $x \in \mathbb{R}$ as

$$
\begin{equation*}
C(Y, x):=[\ell(Y, x), r(Y, x)] \tag{2.5.1}
\end{equation*}
$$

where $\ell(Y, x)=\sup \{y \leq x: Y(y)=0\}$ and $r(Y, x)=\inf \{y \geq x: Y(y)=0\}$.
If $Y(x)=0$, this implies $C(Y, x)=\{x\}$.
We consider a Poisson measure

$$
\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)
$$

on $[0, \infty) \times \mathbb{R}$ with intensity measure $\mathrm{d} t \mathrm{~d} x$, whose marks correspond to matches. We also introduce a Poisson measure

$$
\pi_{S}(\mathrm{~d} t, \mathrm{~d} x, \mathrm{~d} \ell)
$$

on $[0, \infty) \times \mathbb{R} \times[0, \infty)$, independent of $\pi_{M}$, with intensity measure

$$
\mathrm{d} t \mathrm{~d} x \beta(\beta+1) \ell^{-\beta-2} \mathrm{~d} \ell
$$

Roughly, when $\pi_{S}$ has mark $(\tau, X, L)$, this means that no seed fall on $X$ during $[\tau-L, \tau]$. In all the other zones, seeds fall continuously.

Before handling the precise construction of the limit process, let us say roughly what happens. Matches fall according to $\pi_{M}$. Draw a vertical dotted segment at $X$ between $\tau-L$ and $\tau$ for each mark $(\tau, X, L)$ of $\pi_{S}$. Start from time 0 . All the sites become immediately occupied, except sites for which there is a dotted vertical segment crossing $t=0$. These sites remain vacant until the height of these segments. Thus we overwrite in plain the parts of these segments above zero. When there is a fire at some time $t_{0}$, it destroys a zone delimited by some active plain segments. But all the sites in this zone are immediately occupied again, except those for which there is a dotted vertical segment crossing $t=t_{0}$. Such sites will remain vacant until the height of these segments, so that we overwrite in plain the parts of these segments above $t_{0}$. And so on. Of course, plain segments represent vacant sites. See Figure 4 next page for an illustration.

We now handle the rigorous construction on a fixed time interval $[0, T]$. First, we set

$$
Y_{t}^{0}(x)=\mathbb{1}_{\left\{\pi_{S}(\{(s, x, \ell): s>t, s-\ell<0\})=0\right\}}
$$

for all $t \in[0, T]$, all $x \in \mathbb{R}$. Observe that for all $x \in \mathbb{R}, t \mapsto Y_{t}^{0}(x)$ is non-decreasing on $[0, T]$. Since $\int_{0}^{\infty} \int_{0}^{\infty} \mathbb{1}_{\{s>T, s-\ell<0\}} \beta(\beta+1) \ell^{-\beta-2} \mathrm{~d} \ell \mathrm{~d} s>0$, one can clearly find an unbounded family $\left\{\chi_{i}\right\}_{i \in \mathbb{Z}} \subset \mathbb{R}$ such that for all $t \in[0, T]$, all $i \in \mathbb{Z}, Y_{t}^{0}\left(\chi_{i}\right)=0$. We take the convention that for all $i \in \mathbb{Z}$,

$$
\chi_{i} \leq \chi_{i+1}, \quad \chi_{0} \leq 0<\chi_{1}, \quad \lim _{i \rightarrow-\infty} \chi_{i}=-\infty \quad \text { and } \quad \lim _{i \rightarrow \infty} \chi_{i}=\infty
$$

We now handle the construction on each box $[0, T] \times\left[\chi_{i}, \chi_{i+1}\right]$ separately. Let thus $i$ be fixed. The Poisson measure $\pi_{M}$ has a.s. a finite number $n_{i}$ of marks $\left(\rho_{1}^{i}, \alpha_{1}^{i}\right), \ldots,\left(\rho_{n_{i}}^{i}, \alpha_{n_{i}}^{i}\right)$ in $[0, T] \times\left[\chi_{i}, \chi_{i+1}\right]$, ordered in such a way that $0<\rho_{1}^{i}<\cdots<\rho_{n_{i}}^{i}$.

We consider the occupied cluster $I_{1}^{i}=C\left(Y_{\rho_{1}^{i}-}^{0}, \alpha_{1}^{i}\right)$ (which is included in $\left[\chi_{i}, \chi_{i+1}\right]$ by construction). For $(t, x) \in[0, T] \times\left[\chi_{i}, \chi_{i+1}\right]$, we set

$$
Y_{t}^{1}(x)=\mathbb{1}_{\left\{\pi \pi_{S}\left(\left\{(s, x, \ell): s>t, s-\ell<\rho_{1}^{i}\right\}\right)=0\right\}}
$$

if $(t, x) \in\left[\rho_{1}^{i}, T\right] \times I_{1}^{i}$ and $Y_{t}^{1}(x)=Y_{t}^{0}(x)$ else.

Figure 4. LFF $(\beta)$-process with $\beta \in(0, \infty)$.
The plain segments represent vacant sites and the occupied clusters are delimited by these segments. The marks of $\pi_{M}$ (matches) are represented as $\bullet$ 's.

Step 0. - First, we draw on the whole space $[0, \infty) \times \mathbb{R}$ all the $\bullet$ 's and we draw a vertical dotted segment from $(\tau-L, X)$ to $(\tau, X)$ when $\pi_{S}$ has a mark at $(\tau, X, L)$. Of course, such segments are infinitely many so that it is not possible to draw all of them on a figure.

Step 1. - For each of these dotted segments that encounter the axis $t=0$, we overwrite in plain its part above $t=0$. Then we denote by $\chi_{0}$ and $\chi_{1}$ the first places on the left and right of 0 such that plain segments go beyond $T$. At this stage, we have built $\left(Y_{t}^{0}(x)\right)_{t \in[0, T], x \in \mathbb{R}}$.

Step 3. - At time $\rho_{1}^{0}$, we consider the component $I_{1}^{0}$ (between plain segments) where the match $\bullet$ falls. Then, for each dotted segment (lying in $I_{1}^{0}$ ) that encounters the axis $t=\rho_{1}^{0}$, we overwrite in plain its part above $t=\rho_{1}^{0}$. At this stage, we have built $\left(Y_{t}^{1}(x)\right)_{t \in[0, T], x \in\left[\chi_{0}, \chi_{1}\right]}$.

Step 3. - At time $\rho_{2}^{0}$, we consider the component $I_{2}^{0}$ (between plain segments) where the match • falls. Then, for each dotted segment (lying in $I_{2}^{0}$ ) that encounters the axis $t=\rho_{2}^{0}$, we overwrite in plain its part above $t=\rho_{2}^{0}$. We have built $\left(Y_{t}^{2}(x)\right)_{t \in[0, T], x \in\left[\chi_{0}, \chi_{1}\right]}$.
And so on...
Remark. If we draw a vertical dotted segment from $(\tau-L, X)$ to $(\tau, X)$ when $\pi_{S}$ has a mark at $(\tau, X, L)$ only if $L>\delta$, and if $\delta>0$ is smaller than $\min \left\{\rho_{1}^{0}, \rho_{2}^{0}-\rho_{1}^{0}, \rho_{3}^{0}-\rho_{2}^{0}\right\}$, then we get the exact values of $Y_{t}(x)$ for all $x \in\left[\chi_{0}, \chi_{1}\right]$ and all $t \in[0, T] \backslash\left([0, \delta] \cup\left[\rho_{1}^{0}, \rho_{1}^{0}+\delta\right] \cup\left[\rho_{2}^{0}, \rho_{2}^{0}+\delta\right] \cup\left[\rho_{3}^{0}, \rho_{3}^{0}+\delta\right]\right)$.

Assume that for some $k=2, \ldots, n_{i},\left(Y_{t}^{k-1}(x)\right)_{t \in[0, T], x \in\left[\chi_{i}, \chi_{i+1}\right]}$ has been built and consider the occupied cluster $I_{k}^{i}=C\left(Y_{\rho_{k}^{i}-}^{k-1}, \alpha_{k}^{i}\right)$ (which is still included in $\left[\chi_{i}, \chi_{i+1}\right]$ ). For $(t, x) \in[0, T] \times\left[\chi_{i}, \chi_{i+1}\right]$, we define $Y_{t}^{k}(x)$ by setting

$$
Y_{t}^{k}(x)=\mathbb{1}_{\left\{\pi_{S}\left(\left\{(s, x, \ell): s>t, s-\ell<\rho_{k}^{i}\right\}\right)=0\right\}}
$$

if $(t, x) \in\left[\rho_{k}^{i}, T\right] \times I_{k}^{i}$ and $Y_{t}^{k}(x)=Y_{t}^{k-1}(x)$ else.

We finally set $Y_{t}(x)=Y_{t}^{n_{i}}(x)$ for all $t \in[0, T]$, all $x \in\left[\chi_{i}, \chi_{i+1}\right]$. Doing this for each $i$, this defines a process $\left(Y_{t}(x)\right)_{t \in[0, T], x \in \mathbb{R}}$.

A typical path of the $\operatorname{LFF}(\beta)$-process is drawn and discussed on Figure 4, from which the following remark is clear.

REmark 2.5.1. - (i) If we build the process using some larger final time $T^{\prime}>T$, this does not change the values of the process on $[0, T] \times \mathbb{R}$. Thus the process can be extended to $[0, \infty) \times \mathbb{R}$.
(ii) For $\delta>0$, denote by $\pi_{S}^{\delta}$ the restriction of $\pi_{S}$ to $[0, \infty) \times \mathbb{R} \times[\delta, \infty)$. The sequence $\left(\chi_{i}\right)_{i \in \mathbb{Z}}$ clearly depends only on $\pi_{S}^{T}$. Then for each $i \in \mathbb{Z}$, we denote

$$
\mathcal{T}_{M}^{i, T}=\left\{t \in[0, T]: \pi_{M}\left(\{t\} \times\left[\chi_{i}, \chi_{i+1}\right]\right)>0\right\} \cup\{0\}, \quad \delta_{i, T}=\inf _{\substack{s, t \in \mathcal{T}_{M i}^{i, T} \\ s \neq t}}|t-s| .
$$

Then for all $\delta \in\left(0, \delta_{i, T} \wedge T\right)$, all $x \in\left[\chi_{i}, \chi_{i+1}\right]$ and all $t \in[0, T] \backslash \bigcup_{s \in \mathcal{T}_{M}^{i, T}}[s, s+\delta]$, the value of $Y_{t}(x)$ depends only on $\pi_{M}, \pi_{S}^{\delta}$.

Observe that for all $t \geq 0,\left\{Y_{t}=0\right\}$ is countable and for all $t>0$ such that $\pi_{M}(\{t\} \times \mathbb{R})=0,\left\{Y_{t}=0\right\}$ is discrete (it has no accumulation point).

Proposition 2.5.2. - Let $\pi_{M}, \pi_{S}$ be two independent Poisson measures on $[0, \infty) \times \mathbb{R}$ and $[0, \infty) \times \mathbb{R} \times[0, \infty)$ with intensity measures $\mathrm{d} t \mathrm{~d} x$ and $\mathrm{d} t \mathrm{~d} x \beta(\beta+1) \ell^{-\beta-2} \mathrm{~d} \ell$. There a.s. exists a unique $\operatorname{LFF}(\beta)$-process $\left(Y_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$. It can be simulated exactly on any finite box $[0, T] \times[-n, n]$. For each $t \geq 0$ and $x \in \mathbb{R}$, we set $D_{t}(x)=C\left(Y_{t}, x\right)$, recall (2.5.1).

This proposition is obvious from the previous construction. Of course, we can build exactly the process on any finite box, but we cannot draw it exactly: when a match falls in some occupied cluster $I$ at some time $t$, the set $\left\{x \in I: Y_{t}(x)=0\right\}$ is dense in $I$ (but $\left\{x \in I: Y_{t+\varepsilon}(x)=0\right\}$ is finite for all small $\varepsilon>0$ ).

Note that it would have been more natural to set $Y_{t}(x)=0$ for all $x \in I$ when a match falls in some occupied cluster $I$ at some time $t$. However, since then $I$ becomes occupied almost everywhere immediately after $t$, the present definition (which only implies that $\left\{x \in I: Y_{t}(x)=0\right\}$ is dense in $\left.I\right)$ is simpler for mathematical purpose.
2.5.2. On the Markov property. - The $\operatorname{LFF}(\beta)$-process $\left(Y_{t}(x)\right)_{t \geq 0}$ is clearly not Markov, in particular because the heights of the barriers are not exponentially distributed. The aim of this subsection is to build a Markov process that contains more information than $\left(Y_{t}(x)\right)_{t \geq 0}$.

Let the Poisson measures $\pi_{M}$ and $\pi_{S}$ be given. Write $\pi_{S}=\sum_{k \geq 1} \delta_{\left(t_{k}, x_{k}, \ell_{k}\right)}$ and introduce

$$
\pi_{S}^{1}=\sum_{k \geq 1} \delta_{\left(t_{k}-\ell_{k}, x_{k}, \ell_{k}\right)} \mathbb{1}_{\left\{t_{k}-\ell_{k}>0\right\}}, \quad \pi_{S}^{0}=\sum_{k \geq 1} \delta_{\left(t_{k}, x_{k}, \ell_{k}\right)} \mathbb{1}_{\left\{t_{k}-\ell_{k}<0\right\}} .
$$

Observe that $\pi_{S}^{0}$ and $\pi_{S}^{1}$ are independent. Furthermore, $\pi_{S}^{1}$ has a mark $(\tau, X, L)$ if and only if there is a dotted vertical segment from $(\tau, X)$ to $(\tau+L, X)$ (with $\tau>0$ ) and $\pi_{S}^{0}$ has a mark $(\tau, X, L)$ if and only if there is a dotted vertical segment from $(\tau-L, X)$ to $(\tau, X)$ (with $\tau-L<0<\tau)$. One can easily check that $\pi_{S}^{1}$ is a Poisson measure on $[0, \infty) \times \mathbb{R} \times(0, \infty)$ with intensity measure $\mathrm{d} t \mathrm{~d} x \beta(\beta+1) \ell^{-\beta-2} \mathrm{~d} \ell$. We set, for $x \in \mathbb{R}$,

$$
\Gamma_{0}(x)=\int_{0}^{\infty} \int_{0}^{\infty} s \pi_{S}^{0}(\mathrm{~d} s \times\{x\} \times \mathrm{d} \ell)
$$

which represents the height above 0 of the dotted (or plain) vertical segment at $x$ that crosses the axis $t=0$, with of course $\Gamma_{0}(x)=0$ if there is no such dotted segment. We then introduce, for $x \in \mathbb{R}$ and $t \geq 0$,

$$
\Gamma_{t}(x)=\Gamma_{0}(x)+\int_{0}^{t} \int_{0}^{\infty} \max \left\{\ell-\Gamma_{s-}(x), 0\right\} \pi_{S}^{1}(\mathrm{~d} s \times\{x\} \times \mathrm{d} \ell)-\int_{0}^{t} \mathbb{1}_{\left\{\Gamma_{s}(x)>0\right\}} \mathrm{d} s
$$

which represents the height above $t$ of the dotted (or plain) vertical segment at $x$ that crosses the horizontal axis with ordinate $t$, with $\Gamma_{t}(x)=0$ if there is no such dotted segment. Indeed, $\Gamma_{t}(x)$ clearly decreases linearly when it is positive, and jumps from $\Gamma_{s-}(x)$ to $\max \left\{\Gamma_{s-}(x), \ell\right\}$ when $\pi_{S}^{1}$ has a mark at $(s, x, \ell)$. Using the fact that a.s., for all $x \in \mathbb{R}$, there is at most one dotted segment at $x$, it is possible to replace $\max \left\{\ell-\Gamma_{s-}(x), 0\right\}$ by $\ell$. Finally, we define, for $x \in \mathbb{R}$ and $t \geq 0$,

$$
\begin{aligned}
& H_{t}(x)=\Gamma_{0}(x)+\int_{0}^{t} \int_{\mathbb{R}} \mathbb{1}_{\left\{y \in \dot{C}\left(Y_{s-}, x\right)\right\}} \Gamma_{s-}(x) \pi_{M}(\mathrm{~d} s, \mathrm{~d} y)-\int_{0}^{t} \mathbb{1}_{\left\{H_{s}(x)>0\right\}} \mathrm{d} s \\
& Y_{t}(x)=\mathbb{1}_{\left\{H_{t}(x)=0\right\}}
\end{aligned}
$$

where $\stackrel{\circ}{C}\left(Y_{s-}, x\right)$ stands for the interior of $C\left(Y_{s-}, x\right)$. Then $H_{t}(x)$ is the height above $t$ of the plain segment at $x$ that crosses the horizontal axis with ordinate $t$ (with $H_{t}(x)=0$ if there is no such plain segment), and thus $\left(Y_{t}(x)\right)_{t \geq 0}$ is the $\operatorname{LFF}(\beta)$ process. Indeed, since we overwrite in plain all the dotted segments that cross the axis $t=0$, we clearly have $H_{0}(x)=\Gamma_{0}(x)$. Then $H_{t}(x)$ decreases linearly when it is positive, and jumps to $\Gamma_{s-}(x)$ when $x$ is involved in a fire at some time $s$ (whence necessarily $\left.H_{s-}(x)=0\right)$ : recall that we then overwrite in plain the dotted segment at $x$ that crosses the horizontal axis with ordinate $s$, of which the height above $s$ it given by $\Gamma_{s-}(x)$.

The process $\left(\Gamma_{t}(x), H_{t}(x), Y_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ is Markov, since it solves a well-posed homogeneous Poisson-driven S.D.E.
2.5.3. The convergence result. - We now state our main result in the case $\beta \in(0, \infty)$. We use subsection 2.1.5.

Theorem 2.5.3. - Assume $\left(H_{M}\right)$ and $\left(H_{S}(\beta)\right)$ for some $\beta \in(0, \infty)$. Consider, for each $\lambda \in(0,1]$, the process $\left(D_{t}^{\lambda}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ associated with the $\mathrm{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process,
see Definition 2.1.3 and (2.2.3). Consider also a $\operatorname{LFF}(\beta)$-process $\left(Y_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ and set $D_{t}(x)=C\left(Y_{t}, x\right)$ for all $t \geq 0$, all $x \in \mathbb{R}$ as in Proposition 2.5.2.
(a) For any $T>0$, any finite subset $\left\{x_{1}, \ldots, x_{p}\right\} \subset \mathbb{R},\left(D_{t}^{\lambda}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p}$ goes in law to $\left(D_{t}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p}$ in $\mathbb{D}([0, T], \mathcal{I})^{p}$, as $\lambda \rightarrow 0$. Here $\mathbb{D}([0, T], \mathcal{I})$ is endowed with $\boldsymbol{\delta}_{T}$.
(b) For any finite subset $\left\{\left(t_{1}, x_{1}\right), \ldots,\left(t_{p}, x_{p}\right)\right\} \subset(0, \infty) \times \mathbb{R},\left(D_{t_{i}}^{\lambda}\left(x_{i}\right)\right)_{i=1, \ldots, p}$ goes in law to $\left(D_{t_{i}}\left(x_{i}\right)\right)_{i=1, \ldots, p}$ in $\mathcal{I}^{p}, \mathcal{I}$ being endowed with $\boldsymbol{\delta}$.
2.5.4. Heuristic arguments. - We assume below that $\lambda>0$ is very small.
0. Matches. - Exactly as in the case $\beta=\infty$, we hope that matches will fall, in our scales, according to a Poisson measure with intensity 1 (in mean, 1 match per unit of time per unit of space, which corresponds to 1 match per $\boldsymbol{n}_{\lambda}$ sites during $\left[0, \boldsymbol{a}_{\lambda}\right]$ in the original scales).

1. Occupation of vacant zones. - Consider a zone $[a, b]$ (or $\llbracket\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor,\left\lfloor b \boldsymbol{n}_{\lambda}\right\rfloor \rrbracket$ in the original scales). At time 0 , this zone is completely empty. In this zone, each site will be empty at time $t$ if no seed has fallen during $[0, t]$ (or $\left[0, a_{\lambda} t\right]$ in the original scale). This occurs with probability $\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)$. Thus in the absence of fires, the number of empty sites in $[a, b]$ at time $t$ follows a binomial distribution with parameters $(b-a) \boldsymbol{n}_{\lambda}$ and $\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)$. Recalling (2.2.1), (2.2.2) and $\left(H_{S}(\beta)\right)$, we see that

$$
(b-a) \boldsymbol{n}_{\lambda} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right) \simeq(b-a) \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right) / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right) \longrightarrow(b-a) t^{-\beta}
$$

Hence the number of empty sites in $[a, b]$ at time $t$ follows approximately a Poisson law with parameter $(b-a) t^{-\beta}$ (when neglecting fires).

The link with the $\operatorname{LFF}(\beta)$-process is simple: for any $a<b$ and any $t>0$, the random variable $\left.\pi_{S}(\{(s, x, \ell): x \in[a, b], s>t, s-\ell<0)\}\right)$ follows a Poisson law with parameter

$$
\int_{t}^{\infty} \mathrm{d} s \int_{a}^{b} \mathrm{~d} x \int_{s}^{\infty} \beta(\beta+1) \ell^{-\beta-2} \mathrm{~d} \ell=(b-a) t^{-\beta}
$$

2. Fires. - Now when a match falls at some place, this destroys the whole occupied cluster. The destroyed cluster is then treated as in point 1.

The rigorous proof is, as usual, not so easy. The first step is to find a suitable coupling between the seed processes $\left(N_{t}^{S}(i)\right)_{t \geq 0}$ and the Poisson measure $\pi_{S}$ describing times/places where seeds do not fall in the limit process. Next, we have to find a (necessarily complicated) event on which the normalized discrete process resembles the limit process and to show that this event occurs with high probability. For example, this event has to guarantee us that for sites on which seeds fall continuously in the limit process, seeds fall sufficiently often in the discrete process. We also need that a small error in the time/place where a fire starts (or where a seed falls) does not produce large errors after some time, etc.
2.5.5. Cluster-size distribution. - We aim here to estimate the law of the occupied cluster around 0 . No phase transition occurs here.

Corollary 2.5.4. - Let $\beta \in(0, \infty)$. Assume $\left(H_{M}\right)$ and $\left(H_{S}(\beta)\right)$. Recall that $a_{\lambda}$ and $n_{\lambda}$ were defined in (2.2.1) and (2.2.2). Consider the $\operatorname{LFF}(\beta)$ process $\left(Y_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ and the associated $\left(D_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$. For each $\lambda \in(0,1]$, let $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ be a $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process. There are constants $0<c_{1}<c_{2}$ and $0<\kappa_{1}<\kappa_{2}$ such that for all $t \geq 1$ and all $B>0$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|C\left(\eta_{a_{\lambda} t}^{\lambda}, 0\right)\right| \geq B \boldsymbol{n}_{\lambda}\right]=\operatorname{Pr}\left[\left|D_{t}(0)\right| \geq B\right] \in\left[c_{1} \mathrm{e}^{-\kappa_{2} B}, c_{2} \mathrm{e}^{-\kappa_{1} B}\right]
$$

### 2.6. Main results when $\beta=0$

2.6.1. Definition of the limit process. - In this case, the limiting process is trivial: we consider a Poisson measure $\pi_{S}$ on $\mathbb{R}$ with intensity measure $\mathrm{d} x$ and we put, for all $t \geq 0$, all $x \in \mathbb{R}$,

$$
Y_{t}(x)=\mathbb{1}_{\left\{\pi_{S}(x)=0\right\}} .
$$

Denote by $\left\{\chi_{i}\right\}_{i \in \mathbb{Z}}$ the marks of $\pi_{S}$ with the convention that $\cdots<\chi_{-1}<\chi_{0}<0<$ $\chi_{1}<\chi_{2}<\ldots$. Then for all $t \geq 0$, all $i \in \mathbb{Z}$, recalling (2.5.1), $C\left(Y_{t}, x\right)=\left[\chi_{i}, \chi_{i+1}\right]$ for all $x \in\left(\chi_{i}, \chi_{i+1}\right)$ and $C\left(Y_{t}, \chi_{i}\right)=\left\{\chi_{i}\right\}$. Matches fall according to a Poisson measure $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)$ on $[0, \infty) \times \mathbb{R}$ with intensity measure $\mathrm{d} t \mathrm{~d} x$.

The $\operatorname{LFF}(0)$-process $\left(Y_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ is obviously Markov and the following statement is trivial.

Proposition 2.6.1. - Let $\pi_{S}$ be a Poisson measure on $\mathbb{R}$ with intensity measure $\mathrm{d} x$. There a.s. exists a unique $\operatorname{LFF}(0)$-process $\left(Y_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$. It can be simulated exactly on any finite box $[0, T] \times[-n, n]$. For each $t \geq 0$ and $x \in \mathbb{R}$, we will denote by $D_{t}(x)=C\left(Y_{t}, x\right)$ the occupied cluster around $x$ (see (2.5.1)).

Of course, fires do not appear in the construction. Hence it is not necessary to introduce $\pi_{M}$. However, it allows us to keep in mind that fires do occur. But these fires generate empty zones that are immediately regenerated. The main idea is that in our scales: on the great majority of sites, seeds fall almost continuously for all times; but there are rare sites where the first seed will never fall. Hence when there is a fire, this always concerns a zone where seeds fall continuously, so that one does not observe the fire at the limit. A typical path of the LFF(0)-process is commented on Figure 5 next page.
2.6.2. The convergence result. - We now state our last main result, using subsection 2.1.5.

Theorem 2.6.2. - Assume $\left(H_{M}\right)$ and $\left(H_{S}(0)\right)$. Consider, for each $\lambda \in(0,1]$, the process $\left(D_{t}^{\lambda}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ associated to the $\mathrm{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process, see Definition 2.1.3

Figure 5. LFF(0)-process.
The marks of $\pi_{M}$ (matches) are represented as $\bullet$ 's. We draw a plain vertical segment above each mark of $\pi_{S}$. For all times, the occupied clusters are delimited by these vertical segments. In some sense, fires have an instantaneous effect, represented as dotted horizontal segments, that we decided to neglect for obvious practical reasons.
and (2.2.3). Consider also the $\operatorname{LFF}(0)$-process $\left(Y_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ and the associated $\left(D_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$.
(a) For any $T>0$, any finite subset $\left\{x_{1}, \ldots, x_{p}\right\} \subset \mathbb{R},\left(D_{t}^{\lambda}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p}$ goes in law to $\left(D_{t}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p}$ in $\mathbb{D}([0, T], \mathcal{I})^{p}$ as $\lambda \rightarrow 0$. Here $\mathbb{D}([0, \infty), \mathcal{I})$ is endowed with $\boldsymbol{\delta}_{T}$.
(b) For any finite subset $\left\{\left(t_{1}, x_{1}\right), \ldots,\left(t_{p}, x_{p}\right)\right\} \subset(0, \infty) \times \mathbb{R},\left(D_{t_{i}}^{\lambda}\left(x_{i}\right)\right)_{i=1, \ldots, p}$ goes in law to $\left(D_{t_{i}}\left(x_{i}\right)\right)_{i=1, \ldots, p}$ in $\mathcal{I}^{p}, \mathcal{I}$ being endowed with $\boldsymbol{\delta}$.
2.6.3. Heuristic arguments. - The only difference with the case $\beta \in(0, \infty)$ is the following. In some sense, for each site $i$, in our scales, either seeds fall continuously on $i$, or the first seed never falls on $i$. A first hint for this is the following.

Consider a zone $[a, b]$. At time 0 , this zone is completely vacant. Fix $T>0$. Then in the absence of fires, the number of vacant sites in $[a, b]$ at time $T$ (or in $\llbracket\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor,\left\lfloor b \boldsymbol{n}_{\lambda}\right\rfloor \rrbracket$ at time $\boldsymbol{a}_{\lambda} T$ in the original scales) follows a binomial distribution with parameters $(b-a) \boldsymbol{n}_{\lambda}$ and $\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} T, \infty\right)\right)$. Observe now that for any value of $T>0$,
using $\left(H_{S}(0)\right),(2.2 .1)$ and (2.2.2),

$$
(b-a) \boldsymbol{n}_{\lambda} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} T, \infty\right)\right) \simeq(b-a) \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} T, \infty\right)\right) / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right) \longrightarrow(b-a)
$$

Hence the number of sites that are still vacant at time $T$ follows approximately a Poisson distribution with parameter $(b-a)$. Since this parameter does not decrease with $T$, this means that in our scales, sites are either immediately occupied or vacant forever.

Here the rigorous proof is rather simple, but it still needs some care. We have essentially the same difficulties as in the case where $\beta \in(0, \infty)$ (see subsection 2.5.4), but they are more easily treated.
2.6.4. Cluster-size distribution. - Since the LFF(0)-process is very simple, we obtain of course some more precise information on the asymptotic cluster-size distribution.

Remark 2.6.3. - Assume $\left(H_{M}\right)$ and $\left(H_{S}(0)\right)$. For each $\lambda \in(0,1]$, let a $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ be given, see Definition 2.1.3. Consider the $\operatorname{LFF}(0)$-process $\left(Y_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ and the associated $\left(D_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$. Then for $t>0$ and $B>0$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|C\left(\eta_{a_{\lambda} t}^{\lambda}, 0\right)\right| \geq B \boldsymbol{n}_{\lambda}\right]=\operatorname{Pr}\left[\left|D_{t}(0)\right| \geq B\right]=\int_{B}^{\infty} x \mathrm{e}^{-x} \mathrm{~d} x=(B+1) \mathrm{e}^{-B}
$$

No proof is needed here: $x \mathrm{e}^{-x} \mathbb{1}_{\{x>0\}}$ is just the density of $\left|D_{t}(0)\right|=\chi_{1}-\chi_{0}$. The convergence in law of $\left|C\left(\eta_{a_{\lambda} t}^{\lambda}, 0\right)\right| / \boldsymbol{n}_{\lambda}=\left|D_{t}^{\lambda}(0)\right|$ to $\left|D_{t}(0)\right|$ follows from Theorem 2.6.2.

### 2.7. On some other modelling choices

For $\mu$ a probability law on $(0, \infty)$, we say that $N_{t}=\sum_{n \geq 1} \mathbb{1}_{\left\{X_{1}+\cdots+X_{n} \leq t\right\}}$ is a natural renewal process with parameter $\mu$, or a $N R(\mu)$-process in short, if the random variables $X_{i}$ are i.i.d. with law $\mu$. When extending the traditional forest fire model (where all the renewal processes are Poisson), we had to make some choices.

1. Matches can fall according to i.i.d. (i) $\operatorname{SR}\left(\mu_{M}^{\lambda}\right)$-processes, (ii) $N R\left(\mu_{M}^{\lambda}\right)$ processes.
2. Seeds can fall according to i.i.d. (i) $\mathrm{SR}\left(\mu_{S}\right)$-processes, (ii) $N R\left(\mu_{S}\right)$-processes.
3. When a fire destroys an occupied component $\llbracket a, b \rrbracket$, we can (i) keep the i.i.d. renewal processes governing seeds as they are, (ii) forget everything and make start some new i.i.d. renewal processes governing seeds in the zone $\llbracket a, b \rrbracket$.

Recall that when dealing with Poisson processes, choosing (i) or (ii) in points $1,2,3$ does not change the law of the $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process.

From the point of view of modelling, it seemed more natural to choose (i) in points 1 and 2 : this is the only way that time 0 does not play a special role. We also decided
to choose (i) in point 3, because its seems more close to applications. Let us discuss briefly what could happen with other choices.

First, for matches (point 1), choosing (i) does not play a fundamental role. Indeed, in our scales, only 0 or 1 match can fall on each site. Thus our results should extend, without difficulty, to the choice 1 (ii), replacing $\left(H_{M}\right)$ by the assumption $\mu_{M}^{\lambda}((0, t)) \simeq \lambda t$ as $\lambda \rightarrow 0$ (together with some additional regularity conditions if we want a strong coupling as in Proposition 3.2.1).

Next, we believe that in point 2, our results should still hold if choosing (ii) when $\beta=\infty$. In the case where $\mu_{S}$ has a bounded support, one would have to assume some regularity on $\mu_{S}$ (the case $\mu_{S}=\delta_{1}$ is trivial) and to modify the dynamics of the $\operatorname{LFF}(B S)$-process (the law $\theta_{u}$ should also depend on time). Our study would completely break down when $\beta \in[0, \infty)$. In the latter case, the situation would be quite intricate and we are not able to predict scales (and, a fortiori, to predict some limit process). Let us explain briefly the situation. If $\beta=\infty$, then $\nu_{S}$ and $\mu_{S}$ have a similar tail (see example 2). Thus the time and space scales we have considered will fit both $\nu_{S}$ and $\mu_{S}$. On the contrary, if $\beta \in[0, \infty)$, the tails of $\mu_{S}$ and $\nu_{S}$ are really different. Consequently, if we accelerate time according to $\mu_{S}$ (in order that for a $N R\left(\mu_{S}\right)$-process, the cluster containing the site 0 burns before time 1 with a positive probability), then this will be too slow for larger times (when a fire destroys a cluster $(a, b)$, this zone $(a, b)$ will never regenerate).

Finally, in point 3, we also believe that choosing (ii) would not change our results when $\beta=\infty$ and not change too much the situation when $\mu_{S}$ has a bounded support. When $\beta \in[0, \infty)$, we expect that this would not change time/space scales, but we would have to modify the limit processes. For example if $\beta=0$, we expect that each time a fire burns a zone $(a, b)$, this zone would regenerate immediately, except in a random number of sites, that follows a Poisson distribution with parameter $(b-a)$. Next if $\beta \in(0, \infty)$, then when a fire burns a zone $(a, b)$ at some time $t$, we would have to pick another Poisson measure $\pi_{S}^{(a, b), t}(d s, \mathrm{~d} x, \mathrm{~d} \ell)$ on $[t, \infty) \times(a, b) \times(0, \infty)$, independent of everything else and use this Poisson measure above $(a, b)$ instead of the original $\pi_{S}$.

### 2.8. Open problems and perspectives

Of course, the main interesting problem is to find a scaling limit of the forestfire process, e.g. when seeds and matches fall according to Poisson processes, in dimension 2 or more. We believe that the 2 -dimensional limit process should enjoy self-organized criticality. However, it is highly probable that our work, though quite complete in dimension 1, does not give the least hint of what could happen in dimension 2. Indeed, all our study is based on the fact that connectedness is very simple in dimension 1: a vacant site is sufficient to stop a fire. One immediately gets convinced
that the situation is much more complicated in higher dimension. A possible intermediary step, that we investigate, is to study the case where the underlying lattice is a tree, in which connectedness is much simpler than in $\mathbb{Z}^{2}$.

A much easier problem, on which we also work, is to study (e.g. in the Poisson case) the possible scaling limits of the forest-fire process, in dimension 1 , when fires propagate at finite speed. We then expect that several limit processes should arise: (i) if fires propagate sufficiently fast, then we should recover the same limit process as when fires propagate at infinite speed, (ii) when fires propagate at some precise speed (to be determined as a function of $\lambda$ ), then we should find a modified limit process, in which the microscopic fires are unchanged, but in which the macroscopic fires propagate at finite speed, (iii) when fires propagate slowly, a quite different limit process should arise.

Other possible variants could be studied. First, one could consider the case where the processes governing seeds are not independent. It should not be too difficult to get some results (probably with the same scaling limits as in the present paper), under a suitable ergodicity assumption. We could also study the case where seeds fall in a random media. For example, choose (independently) for each site some parameter $\lambda_{i}>0$ at random, and assume that seeds fall on this site according to a Poisson process with rate $\lambda_{i}$. In the case where the support of the law governing the $\lambda_{i}$ 's is bounded from below, a scaling limit could reasonably be found and should not differ much from the $\operatorname{LFF}(\infty)$-process. More subtle phenomena could occur if there are some sites with arbitrarily small rate (on which seeds will fall very rarely). And so on.

It also would be very interesting to study the existence and uniqueness of invariant probability measures for the four limit processes, as well as their convergence to equilibrium. The case $\beta=0$ is obvious, since the limit process $\operatorname{LFF}(0)$ is stationary. But the three other cases seem quite intricate. Finite-box versions of these processes obviously converge in law to a unique invariant probability measure. However, we have no idea of how to check that correlations do not become longer and longer when time increases for the true limit processes. Although this problem seems hard, it is probably less difficult to study invariant distributions for the limit processes than for the original forest-fire processes.

Finally, it might be possible (possibly using the ideas of the present paper), to give much stronger versions of Corollaries 2.3.4, 2.4.5, 2.5.4 and Remark 2.6.3 concerning the asymptotics of the cluster-size distribution. For example in the Poisson case (use Corollary 2.3.4 with $\left.\mu_{S}((t, \infty))=\mathrm{e}^{-t}\right)$, we deduce from our convergence result that the probability that the cluster containing 0 is of size $x$, in the original scales and for sufficiently large times, resembles

$$
\frac{1}{(1+x)[\log (1 / \lambda)]} \mathbb{1}_{\{x \in[0,1 /(\lambda \log (1 / \lambda))]\}}+\lambda \log (1 / \lambda) \mathrm{e}^{-x \lambda \log (1 / \lambda)} \mathbb{1}_{\{x \geq 0\}}
$$

in a very weak sense. It would be interesting to prove a stronger version of this claim. For example, it was proved rigorously in Brouwer-Pennanen [17] that there are constants $0<c<C$ such that for all $0<\lambda<1$ and all stationary measures $\mu_{\lambda}$ (invariant by translation) of the forest fire model on $\mathbb{Z}$ with parameter $\lambda$, for all $x<(1 /[\lambda \log (1 / \lambda)])^{\frac{1}{3}}$,

$$
\frac{c}{(1+x) \log (1 / \lambda)} \leq \mu_{\lambda}(|C(\eta, 0)|=x) \leq \frac{C}{(1+x) \log (1 / \lambda)}
$$

Our result shows that at least a weakened version of such inequalities extends to much higher values of $x$, possibly to all $x<1 /\left[\lambda \log ^{2}(1 / \lambda)\right]$. It would be very interesting to prove that these inequalities really hold true for such values of $x$.

## CHAPTER 3

## PROOFS

### 3.1. Graphical construction of the discrete process

The goal of this section is to prove Proposition 2.1.4 by using a graphical construction.

Proof of Proposition 2.1.4. - Our aim is to prove that for any $T>0$, a.s., the values of the $\mathrm{FF}\left(\mu_{S}, \mu_{M}\right)$-process $\left(\eta_{t}(i)\right)_{t \in[0, T], i \in \mathbb{Z}}$ are uniquely determined by $\left(N_{t}^{S}(i), N_{t}^{M}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. Recall that

$$
\nu_{S}(\mathrm{~d} x)=m_{S}^{-1} \mu_{S}((x, \infty)) \mathrm{d} x \quad \text { and } \quad \nu_{M}(\mathrm{~d} x)=m_{M}^{-1} \mu_{M}((x, \infty)) \mathrm{d} x
$$

where $m_{S}$ and $m_{M}$ are the expectations of $\mu_{S}$ and $\mu_{M}$. We consider $h_{0}>0$ such that $\nu_{S}\left(\left[2 h_{0}, \infty\right)\right)>0$ (if $\nu_{S}$ has an unbounded support, any value of $h_{0}$ is possible) and we put $c_{0}=\nu_{S}\left(\left(2 h_{0}, \infty\right)\right) \nu_{M}\left(\left(0, h_{0}\right)\right)>0$. We also set $K=\left\lfloor T / h_{0}\right\rfloor$.

For $n \in \mathbb{Z}$, we consider the event $\Omega_{n, T}$, on which the following conditions are satisfied:
(i) $N_{h_{0}}^{S}(n)=0$;
(ii) $\forall i \in \llbracket 1, K \rrbracket, \quad N_{(i+1) h_{0}}^{S}(n+i)=N_{(i-1) h_{0}}^{S}(n+i)$;
(iii) $\forall i \in \llbracket 1, K \rrbracket, \quad N_{i h_{0}}^{M}(n+i)>N_{(i-1) h_{0}}^{M}(n+i)$.

We first observe that for any $n \in \mathbb{Z}$, using the stationarity of the renewal processes,

$$
\operatorname{Pr}\left[\Omega_{n, T}\right]=\nu_{S}\left(\left(h_{0}, \infty\right)\right) c_{0}^{K}=: c_{T}>0 .
$$

Next we prove that necessarily,

$$
\Omega_{n, T} \subset\left\{\forall t \in[0, T], \exists i \in \llbracket n, n+K \rrbracket, \eta_{t}(i)=0\right\} .
$$

This is not hard:
(i) implies that $\eta_{t}(n)=0$ for $t \in\left[0, h_{0}\right]$, since no seed falls on $n$ during this interval;
(iii) implies that for $i \in \llbracket 1, K \rrbracket$, a match falls on $n+i$ during $\left((i-1) h_{0}, i h_{0} \rrbracket\right.$;
(ii) guarantees us that no seed falls on $n+i$ during $\left((i-1) h_{0},(i+1) h_{0}\right.$ ], whence the site $n+i$ is necessarily vacant during (at least) $\left(i h_{0},(i+1) h_{0}\right]$.
Consequently, on $\Omega_{n, T}$, there is always at least one vacant site in $\llbracket n, n+K \rrbracket$ during

$$
\left[0, h_{0}\right] \cup\left(\bigcup_{i=1, \ldots, K}\left(i h_{0},(i+1) h_{0}\right]\right) \supset[0, T]
$$

(with our choice for $K$, we have $(K+1) h_{0} \geq T$ ).
Hence conditionally on $\Omega_{n, T}$, during $[0, T]$, the fires starting on the right of $n+K$ do not affect the values of the forest fire process on the left of $n$; and the fires starting on the left of $n$ do not affect the values of the forest fire process on the right of $n+K$.

Since $\operatorname{Pr}\left[\Omega_{n, T}\right]=c_{T}>0$, we can find $\cdots<n_{-1}<n_{0}<0<n_{1}<n_{2} \ldots$ such that $\bigcap_{\ell \in \mathbb{Z}} \Omega_{n_{\ell}, T}$ is realized (use that $\Omega_{n, T}$ is independent of $\Omega_{m, T}$ if $|m-n|>K$ ).

We deduce that for any $i \in \mathbb{Z}$, the values of $\left(\eta_{t}(i)\right)_{t \in[0, T]}$ are entirely determined by the values of $\left(N_{t}^{S}(j), N_{t}^{M}(j)\right)_{t \in\left[0,(K+1) h_{0}\right]}$ for a finite number of $j$ 's, namely (at most) $j \in \llbracket n_{k}, n_{\ell}+K \rrbracket$, where $k<\ell$ satisfy $n_{k}+K<i<n_{\ell}$.

We have shown that for any $T>0,\left(\eta_{t}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ is entirely and uniquely defined by the values of $\left(N_{t}^{S}(i), N_{t}^{M}(i)\right)_{t \in\left[0,(K+1) h_{0}\right], i \in \mathbb{Z}}$.

### 3.2. Convergence of matches

In this section, we consider any function $\lambda \mapsto a_{\lambda}$ bounded from below and such that $\boldsymbol{n}_{\lambda}=\left\lfloor 1 /\left(\lambda \boldsymbol{a}_{\lambda}\right)\right\rfloor \rightarrow \infty$. For $A>0$ and $i \in \mathbb{Z}$, we set

$$
A_{\lambda}=\left\lfloor A \boldsymbol{n}_{\lambda}\right\rfloor, \quad I_{A}^{\lambda}=\llbracket-A_{\lambda}, A_{\lambda} \rrbracket, \quad i_{\lambda}=\left[i / \boldsymbol{n}_{\lambda},(i+1) / \boldsymbol{n}_{\lambda}\right) .
$$

The following result will be used to prove our four main theorems.
Proposition 3.2.1. - Assume $\left(H_{M}\right)$. Let $A>0$ and $T>0$ be fixed. We can find, for any $\lambda \in(0,1]$, a coupling between a Poisson measure $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)$ on $[0, \infty) \times \mathbb{R}$ with intensity measure $\mathrm{d} t \mathrm{~d} x$ and a family of i.i.d. $\operatorname{SR}\left(\mu_{M}^{\lambda}\right)$-processes $\left(N_{t}^{M, \lambda}(i)\right)_{i \in \mathbb{Z}, t \geq 0}$ such that for

$$
\Omega_{A, T}^{M}(\lambda):=\left\{\forall t \in[0, T], \forall i \in I_{A}^{\lambda}, \Delta N_{a_{\lambda} t}^{M, \lambda}(i) \neq 0 \text { iff } \pi_{M}\left(\{t\} \times i_{\lambda}\right) \neq 0\right\}
$$

one has $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\Omega_{A, T}^{M}(\lambda)\right]=1$.
This means that in our scales, with a high probability, the matches used in the discrete processes can be prescribed by a Poisson measure, as in the limit processes.

Proof. - We divide the proof into several steps. Observe that

$$
B_{\lambda}:=\bigcup_{i \in I_{A}^{\lambda}} i_{\lambda}=\left[-A_{\lambda} / \boldsymbol{n}_{\lambda},\left(A_{\lambda}+1\right) / \boldsymbol{n}_{\lambda}\right)
$$

(which is approximately $[-A, A]$ ). It of course suffices to build $\pi_{M}$ restricted to $[0, T] \times B_{\lambda}$ and the family $\left(N_{t}^{M, \lambda}(i)\right)$ for $i \in I_{A}^{\lambda}$ and $t \in\left[0, a_{\lambda} T\right]$.

Step 1. - We observe that a possible way to build $\pi_{M}$ (restricted to $[0, T] \times B_{\lambda}$ ) is the following:
(i) Consider a family of i.i.d. r.v. $\left(Z_{i}^{\lambda}\right)_{i \in I_{A}^{\lambda}}$ following a Poisson distribution with parameter $T\left|i_{\lambda}\right|=T / \boldsymbol{n}_{\lambda}$.
(ii) For each $i$ with $Z_{i}^{\lambda}>0$, pick some i.i.d. r.v. $\left(T_{1}^{i, \lambda}, X_{1}^{i, \lambda}\right), \ldots,\left(T_{Z_{i}^{\lambda}}^{i, \lambda}, X_{Z_{i}^{\lambda}}^{i, \lambda}\right)$ with uniform law on $[0, T] \times i_{\lambda}$ (conditionally on $Z_{i}^{\lambda}$ ). Set finally

$$
\pi_{M}=\sum_{i \in I_{A}^{\lambda}} \sum_{k=1}^{Z_{i}^{\lambda}} \delta_{\left(T_{k}^{i, \lambda}, X_{k}^{i, \lambda}\right)}
$$

Step 2. - Next, we note it is possible to build the family $\left(N_{t}^{M, \lambda}(i)\right)_{i \in I_{A}^{\lambda}}, t \in\left[0, a_{\lambda} T\right]$ as follows: introduce

$$
q_{k}(\lambda, T)=\operatorname{Pr}\left[N_{a_{\lambda} T}^{M, \lambda}(i)=k\right] \quad \text { and } \quad \zeta_{k}^{\lambda, T}\left(\mathrm{~d} t_{1}, \ldots, \mathrm{~d} t_{k}\right)
$$

the law of the $k$ jump instants of $N^{M, \lambda}(i)$ in $\left[0, \boldsymbol{a}_{\lambda} T\right]$ conditionally on $\left\{N_{\boldsymbol{a}_{\lambda} T}^{M, \lambda}(i)=k\right\}$.
(i) Consider a family of i.i.d. r.v. $\left(\widetilde{Z}_{i}^{\lambda}\right)_{i \in I_{A}^{\lambda}}$ with law $\left(q_{k}(\lambda, T)\right)_{k \geq 0}$.
(ii) For each $i$ with $\widetilde{Z}_{i}^{\lambda}>0$, pick $\left(\widetilde{T}_{1}^{i, \lambda}, \ldots, \widetilde{T}_{\widetilde{Z}_{i}^{\lambda}}^{i, \lambda}\right)$ according to $\zeta_{\widetilde{Z}_{i}^{\lambda}}^{\lambda, T}\left(\mathrm{~d} t_{1}, \ldots, \mathrm{~d} \tilde{Z}_{\widetilde{Z}_{i}^{\lambda}}\right)$ (conditionally on $\widetilde{Z}_{i}^{\lambda}$ ).
Set finally $N_{t}^{M, \lambda}(i)=\sum_{k=1}^{\widetilde{Z}_{i}^{\lambda}} \mathbb{1}_{\left\{t \geq \widetilde{T}_{k}^{i, \lambda}\right\}}$ for $t \in\left[0, \boldsymbol{a}_{\lambda} T\right], i \in I_{A}^{\lambda}$.
Step 3. - We show in this step that for each $i \in I_{A}^{\lambda}$, one can couple $Z_{i}^{\lambda}$ (as in step 1 (i)) and $\widetilde{Z}_{i}^{\lambda}$ (as in step 2 (i)) in such a way that

$$
\begin{aligned}
& \operatorname{Pr}\left[Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda}=0\right] \geq 1-\lambda \boldsymbol{a}_{\lambda} T\left(1+\varepsilon_{T}(\lambda)\right), \\
& \operatorname{Pr}\left[Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda}=1\right] \geq \lambda \boldsymbol{a}_{\lambda} T\left(1-\varepsilon_{T}(\lambda)\right)
\end{aligned}
$$

where $\lim _{\lambda \rightarrow 0} \varepsilon_{T}(\lambda)=0$. Below, the function $\varepsilon_{T}$ may change from line to line.
It is classically possible (see Lemma 5.1.3 (i)) to build a coupling in such a way that

$$
\begin{aligned}
& \operatorname{Pr}\left[Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda}=0\right] \geq \operatorname{Pr}\left[Z_{i}^{\lambda}=0\right] \wedge \operatorname{Pr}\left[\widetilde{Z}_{i}^{\lambda}=0\right] \\
& \operatorname{Pr}\left[Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda}=1\right] \geq \operatorname{Pr}\left[Z_{i}^{\lambda}=1\right] \wedge \operatorname{Pr}\left[\widetilde{Z}_{i}^{\lambda}=1\right]
\end{aligned}
$$

We now use $\left(H_{M}\right)$ : recalling that $\int_{0}^{\infty} \mu_{M}^{1}((s, \infty)) \mathrm{d} s=1$,

$$
\begin{aligned}
\operatorname{Pr}\left[\widetilde{Z}_{i}^{\lambda}=0\right] & =\nu_{M}^{\lambda}\left(\left(\boldsymbol{a}_{\lambda} T, \infty\right)\right)=\lambda \int_{a_{\lambda} T}^{\infty} \mu_{M}^{1}((\lambda s, \infty)) \mathrm{d} s \\
& =\int_{\lambda a_{\lambda} T}^{\infty} \mu_{M}^{1}((u, \infty)) \mathrm{d} u=1-\int_{0}^{\lambda \boldsymbol{a}_{\lambda} T} \mu_{M}^{1}((u, \infty)) \mathrm{d} u \geq 1-\lambda \boldsymbol{a}_{\lambda} T
\end{aligned}
$$

Since $\operatorname{Pr}\left[Z_{i}^{\lambda}=0\right]=\mathrm{e}^{-T / n_{\lambda}}=\mathrm{e}^{-T /\left\lfloor 1 /\left(\lambda \boldsymbol{a}_{\lambda}\right)\right\rfloor}=1-\lambda \boldsymbol{a}_{\lambda} T\left(1+\varepsilon_{T}(\lambda)\right)$, this concludes the proof of the first lower-bound. Next, recalling Definition 2.1.1 and $\left(H_{M}\right)$,

$$
\begin{aligned}
\operatorname{Pr}\left[\widetilde{Z}_{i}^{\lambda}=1\right] & =\int_{0}^{\boldsymbol{a}_{\lambda} T} \mu_{M}^{\lambda}\left(\left(\boldsymbol{a}_{\lambda} T-s, \infty\right)\right) \nu_{M}^{\lambda}(\mathrm{d} s) \\
& =\int_{0}^{\boldsymbol{a}_{\lambda} T} \mu_{M}^{1}\left(\left(\lambda\left(\boldsymbol{a}_{\lambda} T-s\right), \infty\right)\right) \lambda \mu_{M}^{1}((\lambda s, \infty)) \mathrm{d} s \\
& =\int_{0}^{\lambda a_{\lambda} T} \mu_{M}^{1}\left(\left(\lambda \boldsymbol{a}_{\lambda} T-u, \infty\right)\right) \mu_{M}^{1}((u, \infty)) \mathrm{d} u \\
& =\lambda \boldsymbol{a}_{\lambda} T\left(1-\varepsilon_{T}(\lambda)\right),
\end{aligned}
$$

since $\lambda \boldsymbol{a}_{\lambda} \rightarrow 0$ as $\lambda \rightarrow 0$. But now

$$
\operatorname{Pr}\left[Z_{i}^{\lambda}=1\right]=\left(T / \boldsymbol{n}_{\lambda}\right) \mathrm{e}^{-T / \boldsymbol{n}_{\lambda}}=\lambda \boldsymbol{a}_{\lambda} T\left(1-\varepsilon_{T}(\lambda)\right)
$$

because $\boldsymbol{n}_{\lambda}=\left\lfloor 1 /\left(\lambda \boldsymbol{a}_{\lambda}\right)\right\rfloor$ and this concludes the step.
Step 4. - We now check that for each $i \in I_{A}^{\lambda}$, conditionally on $\left\{Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda}=1\right\}$, we can couple $T_{1}^{i, \lambda}$ and $\widetilde{T}_{1}^{i, \lambda}$ (see steps 1 (ii) and 2 (ii)) in such a way that for

$$
r_{T}(\lambda)=\operatorname{Pr}\left[T_{1}^{i, \lambda}=\widetilde{T}_{1}^{i, \lambda} / \boldsymbol{a}_{\lambda} \mid Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda}=1\right]
$$

$\lim _{\lambda \rightarrow 0} r_{T}(\lambda)=1$. We first recall that $T_{1}^{i, \lambda}$ is uniformly distributed on $[0, T]$ (conditionally on $\left\{Z_{i}^{\lambda}=1\right\}$ ). We next remark that the conditional law of $\widetilde{T}_{1}^{i, \lambda}$ knowing $\left\{\widetilde{Z}_{i}^{\lambda}=1\right\}$ (which we called $\zeta_{1}^{\lambda, T}$ ) is nothing but

$$
\begin{aligned}
\zeta_{1}^{\lambda, T}(\mathrm{~d} t) & =\frac{\nu_{M}^{\lambda}(\mathrm{d} t) \mu_{M}^{\lambda}\left(\left(\boldsymbol{a}_{\lambda} T-t, \infty\right)\right) \mathbb{1}_{\left\{t \in\left[0, \boldsymbol{a}_{\lambda} T\right]\right\}}}{\int_{0}^{\boldsymbol{a}_{\lambda} T} \mu_{M}^{\lambda}\left(\left(\boldsymbol{a}_{\lambda} T-s, \infty\right)\right) \nu_{M}^{\lambda}(\mathrm{d} s)} \\
& =\frac{\mu_{M}^{1}\left(\left(\lambda\left(\boldsymbol{a}_{\lambda} T-t\right), \infty\right)\right) \lambda \mu_{M}^{1}((\lambda t, \infty)) \mathbb{1}_{\left\{t \in\left[0, \boldsymbol{a}_{\lambda} T\right]\right\}}}{\lambda \boldsymbol{a}_{\lambda} T\left(1-\varepsilon_{T}(\lambda)\right)} \mathrm{d} t
\end{aligned}
$$

where we used the same computations as in step 3 . Consequently, the conditional law of $\widetilde{T}_{1}^{i, \lambda} / \boldsymbol{a}_{\lambda}$ knowing $\left\{\widetilde{Z}_{i}^{\lambda}=1\right\}$ has a density $g_{\lambda, T}$ of the form

$$
g_{\lambda, T}(t)=\frac{1+\varepsilon_{T}(\lambda)}{T} \mu_{M}^{1}\left(\left(\lambda \boldsymbol{a}_{\lambda}(T-t), \infty\right)\right) \mu_{M}^{1}\left(\left(\lambda \boldsymbol{a}_{\lambda} t, \infty\right)\right) \mathbb{1}_{\{t \in[0, T]\}}
$$

Observe that $\lim _{\lambda \rightarrow 0} g_{\lambda, T}(t)=T^{-1} \mathbb{1}_{\{t \in[0, T]\}}$, since $\lambda \boldsymbol{a}_{\lambda} \rightarrow 0$. Hence, classical arguments (see Lemma 5.1 .3 (ii)) show that conditionally on $\left\{Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda}=1\right\}$, we can couple $T_{1}^{i, \lambda}$ and $\widetilde{T}_{1}^{i, \lambda}$ in such a way that

$$
\operatorname{Pr}\left[T_{1}^{i, \lambda}=\widetilde{T}_{1}^{i, \lambda} / a_{\lambda} \mid Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda}=1\right] \geq \int_{0}^{T} \min \left(\frac{1}{T}, g_{\lambda, T}(t)\right) \mathrm{d} t
$$

which tends to 1 as $\lambda \rightarrow 0$ by dominated convergence.
Step 5. - We finally may build the complete coupling.
(i) For each $i \in I_{A}^{\lambda}$, we consider some coupled random variables $\left(Z_{i}^{\lambda}, \widetilde{Z}_{i}^{\lambda}\right)$ as in step 3 .
(ii) For $i \in I_{A}^{\lambda}$ such that $Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda}=0$, there is nothing to do.
(iii) For $i \in I_{A}^{\lambda}$ such that $Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda}=1$, couple $T_{1}^{i, \lambda}$ and $\widetilde{T}_{1}^{i, \lambda}$ as in step 4 and pick $X_{1}^{i, \lambda}$ uniformly in $i_{\lambda}$.
(iv) If $i \in I_{A}^{\lambda}$ does not meet one of the two above conditions (ii) and (iii), then we build $\left(T_{1}^{i, \lambda}, X_{1}^{i, \lambda}\right), \ldots,\left(T_{Z_{i}^{\lambda}}^{i, \lambda}, X_{Z_{i}^{\lambda}}^{i, \lambda}\right)$ and $\widetilde{T}_{1}^{i, \lambda}, \ldots, \widetilde{T}_{\widetilde{Z}_{i}^{\lambda}}^{i, \lambda}$ in any way (e.g., follow the rules of step 1 (ii) and step 2 (ii) independently).
(v) For $i \in I_{A}^{\lambda}, t \in\left[0, T \boldsymbol{a}_{\lambda}\right]$, set

$$
\pi_{M}=\sum_{i \in I_{A}^{\lambda}} \sum_{k=1}^{Z_{i}^{\lambda}} \delta_{\left(T_{k}^{i, \lambda}, X_{k}^{i, \lambda}\right)} \quad \text { and } \quad N_{t}^{M, \lambda}(i)=\sum_{k=1}^{\widetilde{Z}_{i}^{\lambda}} \mathbb{1}_{\left\{t \geq \widetilde{T}_{k}^{i, \lambda}\right\}}
$$

Step 6. - Define the event

$$
\widetilde{\Omega}_{A, T}^{M}(\lambda)=\bigcap_{i \in I_{A}^{\lambda}}\left(\left\{Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda}=0\right\} \cup\left\{Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda}=1, T_{1}^{i, \lambda}=\widetilde{T}_{1}^{i, \lambda} / \boldsymbol{a}_{\lambda}\right\}\right) .
$$

Then we have $\widetilde{\Omega}_{A, T}^{M}(\lambda) \subset \Omega_{A, T}^{M}(\lambda)$ (where $\Omega_{A, T}^{M}(\lambda)$ was defined in the statement). Indeed, on $\widetilde{\Omega}_{A, T}^{M}(\lambda)$, for any $i \in I_{A}^{\lambda}, t \in[0, T]$, we have $\Delta N_{a_{\lambda} t}^{M, \lambda}(i) \neq 0$ iff $\left(\widetilde{Z}_{i}^{\lambda}=1\right.$ and $\left.\boldsymbol{a}_{\lambda} t=\widetilde{T}_{1}^{i, \lambda}\right)$ iff $\left(Z_{i}^{\lambda}=1\right.$ and $\left.t=T_{1}^{i, \lambda}\right)$ iff $\pi_{M}\left(\{t\} \times i_{\lambda}\right)>0$.

Finally, using steps 3 and 4 and that $\left|I_{A}^{\lambda}\right|=2 A_{\lambda}+1$,

$$
\begin{aligned}
\operatorname{Pr}\left[\Omega_{A, T}^{M}(\lambda)\right] & \geq\left(\operatorname{Pr}\left[Z_{0}^{\lambda}=\widetilde{Z}_{0}^{\lambda}=0\right]+\operatorname{Pr}\left[Z_{0}^{\lambda}=\widetilde{Z}_{0}^{\lambda}=1, \quad T_{1}^{0, \lambda}=\widetilde{T}_{1}^{0, \lambda} / \boldsymbol{a}_{\lambda}\right]\right)^{2 A_{\lambda}+1} \\
& \geq\left(1-\lambda \boldsymbol{a}_{\lambda} T\left(1+\varepsilon_{T}(\lambda)\right)+\lambda \boldsymbol{a}_{\lambda} T\left(1-\varepsilon_{T}(\lambda)\right) r_{T}(\lambda)\right)^{2 A_{\lambda}+1}
\end{aligned}
$$

Recall that $\lim _{\lambda \rightarrow 0} \varepsilon_{T}(\lambda)=0$, that $\lim _{\lambda \rightarrow 0} r_{T}(\lambda)=1$ and that $A_{\lambda} \leq A /\left(\lambda \boldsymbol{a}_{\lambda}\right)$. Hence for some (other) function $\varepsilon_{T}$ with limit 0 at 0 ,

$$
\operatorname{Pr}\left[\Omega_{A, T}^{M}(\lambda)\right] \geq\left(1-\lambda a_{\lambda} T \varepsilon_{T}(\lambda)\right)^{2 A /\left(\lambda a_{\lambda}\right)+1}
$$

This last quantity tends to 1 as $\lambda \rightarrow 0$, which concludes the proof.

### 3.3. Convergence proof when $\beta \in(0, \infty)$

We split this section into three parts. First, we handle some preliminary computations on $\operatorname{SR}\left(\mu_{S}\right)$-processes. Next, we show how to couple the set of times/locations where no seed fall (in the discrete model) with the Poisson measure $\pi_{S}$. Then we conclude the convergence proof. In the whole section, we assume $\left(H_{M}\right)$ and $\left(H_{S}(\beta)\right)$ for some $\beta \in(0, \infty)$. We recall that $\boldsymbol{a}_{\lambda}$ and $\boldsymbol{n}_{\lambda}$ are defined in (2.2.1) and (2.2.2). For $A>0$ and $i \in \mathbb{Z}$, we set

$$
A_{\lambda}=\left\lfloor A \boldsymbol{n}_{\lambda}\right\rfloor, \quad I_{A}^{\lambda}=\llbracket-A_{\lambda}, A_{\lambda} \rrbracket, \quad i_{\lambda}=\left[i / \boldsymbol{n}_{\lambda},(i+1) / \boldsymbol{n}_{\lambda}\right) .
$$

3.3.1. Preliminary computations. - First, we will need the following estimate.

Lemma 3.3.1. - For any $\ell \in(0, \infty)$ fixed,

$$
\mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right) \sim m_{S} \beta \ell^{-\beta-1} \lambda \text { as } \lambda \rightarrow 0
$$

Proof. - Recall that $\mu_{S}((t, \infty)) \mathrm{d} t=m_{S} \nu_{S}(\mathrm{~d} t)$. For $\alpha>0$, one may write, using the monotonicity of $x \mapsto \mu_{S}((x, \infty))$,

$$
\begin{aligned}
\frac{\mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)}{\lambda} & \geq \frac{1}{\alpha \lambda \boldsymbol{a}_{\lambda}} \int_{\boldsymbol{a}_{\lambda} \ell}^{\boldsymbol{a}_{\lambda}(\ell+\alpha)} \mu_{S}((x, \infty)) \mathrm{d} x \\
& =\frac{m_{S}}{\alpha \lambda \boldsymbol{a}_{\lambda}}\left[\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)-\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}(\ell+\alpha), \infty\right)\right)\right] \\
& =\frac{m_{S}}{\alpha}\left[\frac{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)}{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)}-\frac{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}(\ell+\alpha), \infty\right)\right)}{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)}\right] .
\end{aligned}
$$

For the last equality, we used that by definition, $\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)=\lambda \boldsymbol{a}_{\lambda}$. Due to $\left(H_{S}(\beta)\right)$, we deduce that for any $\alpha>0$,

$$
\liminf _{\lambda \rightarrow 0} \frac{\mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)}{\lambda} \geq \frac{m_{S}}{\alpha}\left[\ell^{-\beta}-(\ell+\alpha)^{-\beta}\right] \geq m_{S} \beta(\ell+\alpha)^{-\beta-1}
$$

One gets an upper bound by the same way: for any $\alpha \in(0, \ell)$,

$$
\limsup _{\lambda \rightarrow 0} \frac{\mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)}{\lambda} \leq \limsup _{\lambda \rightarrow 0} \frac{1}{\alpha \lambda \boldsymbol{a}_{\lambda}} \int_{a_{\lambda}(\ell-\alpha)}^{\boldsymbol{a}_{\lambda} \ell} \mu_{S}((x, \infty)) \mathrm{d} x \leq m_{S} \beta(\ell-\alpha)^{-\beta-1}
$$

We have proved that for any $\alpha \in(0, \ell)$,
$m_{S} \beta(\ell+\alpha)^{-\beta-1} \leq \liminf _{\lambda \rightarrow 0} \frac{\mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)}{\lambda} \leq \limsup _{\lambda \rightarrow 0} \frac{\mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)}{\lambda} \leq m_{S} \beta(\ell-\alpha)^{-\beta-1}$.
Making $\alpha$ tend to 0 allows us to conclude.
Next, we compute the asymptotic probability that on a given site, no seed fall during some large time interval. By large, we mean with a length of order $\boldsymbol{a}_{\lambda}$.

Lemma 3.3.2. - Let $\left(T_{n}\right)_{n \in \mathbb{Z}}$ be a $\operatorname{SR}\left(\mu_{S}\right)$-process (see subsection 2.1.1). For $\lambda>0, t \geq 0$ and $\ell>0$, we set

$$
S_{t}^{\lambda}(\ell)=\#\left\{n \in \mathbb{Z}: T_{n} \in\left[0, a_{\lambda} t\right], T_{n}-T_{n-1} \geq \boldsymbol{a}_{\lambda} \ell\right\}
$$

which represents the number of delays with length greater than $\boldsymbol{a}_{\lambda} \ell$ that end in $\left[0, \boldsymbol{a}_{\lambda} t\right]$.
(i) For $t>0$ and $\ell>0$ fixed, as $\lambda \rightarrow 0$, $\operatorname{Pr}\left[S_{t}^{\lambda}(\ell)=1\right] \sim t \lambda \boldsymbol{a}_{\lambda} \beta \ell^{-\beta-1}$.
(ii) For $t>0$ and $\ell>0$ fixed, $\lim _{\sup }^{\lambda \rightarrow 0}\left(\lambda \boldsymbol{a}_{\lambda}\right)^{-2} \operatorname{Pr}\left[S_{t}^{\lambda}(\ell) \geq 2\right]<\infty$.
(iii) On the event $\left\{S_{t}^{\lambda}(\ell)=1\right\}$, we put

$$
\tau:=T_{n} \quad \text { and } \quad L=T_{n}-T_{n-1}
$$

where $n$ is the unique index such that $T_{n} \in[0, t]$ and $T_{n}-T_{n-1} \geq \boldsymbol{a}_{\lambda} \ell$. For all $s \in[0, t]$, all $x \in(\ell, \infty)$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\tau / \boldsymbol{a}_{\lambda} \leq s, L / \boldsymbol{a}_{\lambda} \geq x \mid S_{t}^{\lambda}(\ell)=1\right]=(s / t)(x / \ell)^{-\beta-1}
$$

Proof. - Let us recall that the $\operatorname{SR}\left(\mu_{S}\right)$-process $\left(T_{n}\right)_{n \in \mathbb{Z}}$ is built as follows: one considers an i.i.d. sequence $\left(X_{i}\right)_{i \in \mathbb{Z} \backslash\{0\}}$ of $\mu_{S}$-distributed r.v., $X_{0}$ a $x \mu_{S}(\mathrm{~d} x) / m_{S}$-distributed r.v. and $U$ uniformly distributed on $[0,1]$. Then we set

$$
T_{0}=-(1-U) X_{0}, \quad T_{1}=U X_{0}
$$

and for all $n \geq 1$,

$$
T_{n+1}=T_{n}+X_{n} \quad \text { and } \quad T_{-n}=T_{-n+1}-X_{-n}
$$

We also introduce, for $\lambda>0, \ell>0$ and $0 \leq s \leq t$

$$
S_{s, t}^{\lambda}(\ell)=\#\left\{n \in \mathbb{Z}: T_{n} \in\left[\boldsymbol{a}_{\lambda} s, \boldsymbol{a}_{\lambda} t\right], T_{n}-T_{n-1} \geq \boldsymbol{a}_{\lambda} \ell\right\}
$$

Step 1. - First assume that $\ell \geq t$. Then by construction, $S_{t}^{\lambda}(\ell) \in\{0,1\}$ and

$$
\left\{S_{t}^{\lambda}(\ell)=1\right\}=\left\{T_{1} \leq \boldsymbol{a}_{\lambda} t, T_{1}-T_{0} \geq \boldsymbol{a}_{\lambda} \ell\right\}=\left\{U X_{0} \leq \boldsymbol{a}_{\lambda} t, X_{0} \geq \boldsymbol{a}_{\lambda} \ell\right\}
$$

Hence

$$
\begin{aligned}
\mathbb{E}\left[S_{t}^{\lambda}(\ell)\right] & =\operatorname{Pr}\left[U X_{0} \leq \boldsymbol{a}_{\lambda} t, X_{0} \geq \boldsymbol{a}_{\lambda} \ell\right] \\
& =\int_{\boldsymbol{a}_{\lambda} \ell}^{\infty} \frac{x \mu_{S}(\mathrm{~d} x)}{m_{S}} \int_{0}^{1} \mathrm{~d} u \mathbb{1}_{\left\{u x \leq \boldsymbol{a}_{\lambda} t\right\}} \\
& =\int_{\boldsymbol{a}_{\lambda} \ell}^{\infty} \frac{x \mu_{S}(\mathrm{~d} x)}{m_{S}} \frac{\boldsymbol{a}_{\lambda} t}{x}=\frac{\boldsymbol{a}_{\lambda} t}{m_{S}} \mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)
\end{aligned}
$$

We used here that since $\ell \geq t$, for $x \geq \boldsymbol{a}_{\lambda} \ell$, there holds $\boldsymbol{a}_{\lambda} t / x \leq 1$.
Step 2. - We now show that for any $\ell>0$, any $t \geq 0$,

$$
\mathbb{E}\left[S_{t}^{\lambda}(\ell)\right]=\frac{\boldsymbol{a}_{\lambda} t}{m_{S}} \mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)
$$

Consider $n \geq 1$ such that $t / n \leq \ell$ and observe that

$$
S_{t}^{\lambda}(\ell)=\sum_{i=0}^{n-1} S_{i t / n,(i+1) t / n}^{\lambda}(\ell)
$$

By stationarity, we have $\mathbb{E}\left[S_{i t / n,(i+1) t / n}^{\lambda}(\ell)\right]=\mathbb{E}\left[S_{t / n}^{\lambda}(\ell)\right]$ for $i=0, \ldots, n-1$, which is nothing but $\frac{a_{\lambda} t}{n m_{S}} \mu_{S}\left(\left(a_{\lambda} \ell, \infty\right)\right)$ by step 1 . The conclusion follows by linearity of expectation.

Step 3. - We now check point (ii). Let

$$
\begin{aligned}
& \rho_{1}=\inf \left\{T_{n}: n \in \mathbb{N}, T_{n}-T_{n-1} \geq \boldsymbol{a}_{\lambda} \ell, T_{n}>0\right\} \\
& \rho_{2}=\inf \left\{T_{n}: n \in \mathbb{N}, T_{n}-T_{n-1} \geq \boldsymbol{a}_{\lambda} \ell, T_{n}>\rho_{1}\right\}
\end{aligned}
$$

Then $\operatorname{Pr}\left[S_{t}^{\lambda}(\ell) \geq 2\right]=\operatorname{Pr}\left[\rho_{2} \leq \boldsymbol{a}_{\lambda} t\right]$. We also observe that

$$
\operatorname{Pr}\left[\rho_{1} \leq \boldsymbol{a}_{\lambda} t\right]=\operatorname{Pr}\left[S_{t}^{\lambda}(\ell) \geq 1\right] \leq \mathbb{E}\left[S_{t}^{\lambda}(\ell)\right]=\boldsymbol{a}_{\lambda} t \mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right) / m_{S}
$$

Denote by $\zeta_{\lambda, \ell}$ the law of $\rho_{1} / \boldsymbol{a}_{\lambda}$. Then a renewal argument shows that

$$
\operatorname{Pr}\left[S_{t}^{\lambda}(\ell) \geq 2\right]=\int_{0}^{t} \zeta_{\lambda, \ell}(\mathrm{d} r) f(\lambda, \ell, t-r)
$$

where

$$
f(\lambda, \ell, s)=\operatorname{Pr}\left[\exists n \geq 1 ; X_{n} \geq \boldsymbol{a}_{\lambda} \ell ; X_{1}+\cdots+X_{n} \leq \boldsymbol{a}_{\lambda} s\right] .
$$

We can rewrite this as (recall that $T_{1}=U X_{0} \sim \nu_{S}$ )

$$
\begin{aligned}
& f(\lambda, \ell, s) \\
& \quad=\operatorname{Pr}\left[\exists n \geq 1 ; X_{n} \geq \boldsymbol{a}_{\lambda} \ell ; U X_{0}+X_{1}+\cdots+X_{n} \leq \boldsymbol{a}_{\lambda} s+U X_{0}\right] \\
& \quad \leq \operatorname{Pr}\left[\exists n \geq 0 ; X_{n} \geq \boldsymbol{a}_{\lambda} \ell ; U X_{0}+X_{1}+\cdots+X_{n} \leq \boldsymbol{a}_{\lambda}(s+1)\right]+\operatorname{Pr}\left[U X_{0} \geq \boldsymbol{a}_{\lambda}\right] \\
& \quad=\operatorname{Pr}\left[S_{s+1}^{\lambda}(\ell) \geq 1\right]+\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right) \\
& \quad=\frac{\boldsymbol{a}_{\lambda}(s+1)}{m_{S}} \mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)+\lambda \boldsymbol{a}_{\lambda}
\end{aligned}
$$

thanks to step 2. As a conclusion,

$$
\begin{aligned}
\operatorname{Pr}\left[S_{t}^{\lambda}(\ell) \geq 2\right] & \leq\left(\frac{\boldsymbol{a}_{\lambda}(t+1)}{m_{S}} \mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)+\lambda \boldsymbol{a}_{\lambda}\right) \int_{0}^{t} \zeta_{\lambda, \ell}(\mathrm{d} r) \\
& =\left(\frac{\boldsymbol{a}_{\lambda}(t+1)}{m_{S}} \mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)+\lambda \boldsymbol{a}_{\lambda}\right) \operatorname{Pr}\left[\rho_{1} \leq \boldsymbol{a}_{\lambda} T\right] \\
& \leq\left(\frac{\boldsymbol{a}_{\lambda}(t+1)}{m_{S}} \mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)+\lambda \boldsymbol{a}_{\lambda}\right) \frac{\boldsymbol{a}_{\lambda} t}{m_{S}} \mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)
\end{aligned}
$$

Due to Lemma 3.3.1, this last term is equivalent to $\left(\lambda a_{\lambda}\right)^{2}\left[(t+1) \beta \ell^{-\beta-1}+1\right] t \beta \ell^{-\beta-1}$, from which point (ii) follows.

Step 4. - Steps 2 and 3 imply point (i). Indeed, we clearly have

$$
\operatorname{Pr}\left[S_{t}^{\lambda}(\ell)=1\right] \leq \mathbb{E}\left[S_{t}^{\lambda}(\ell)\right]=\frac{\boldsymbol{a}_{\lambda} t}{m_{S}} \mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right) \sim t \lambda \boldsymbol{a}_{\lambda} \beta \ell^{-\beta-1}
$$

by Lemma 3.3.1. Next, using that $S_{t}^{\lambda}(\ell) \leq 1+t / \ell$ by construction,

$$
\begin{aligned}
\operatorname{Pr}\left[S_{t}^{\lambda}(\ell)=1\right] & =\mathbb{E}\left[S_{t}^{\lambda}(\ell) \mathbb{1}_{\left\{S_{t}^{\lambda}(\ell)=1\right\}}\right]=\mathbb{E}\left[S_{t}^{\lambda}(\ell)\right]-\mathbb{E}\left[S_{t}^{\lambda}(\ell) \mathbb{1}_{\left\{S_{t}^{\lambda}(\ell) \geq 2\right\}}\right] \\
& \geq \frac{\boldsymbol{a}_{\lambda} t}{m_{S}} \mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)-(1+t / \ell) \operatorname{Pr}\left[S_{t}^{\lambda}(\ell) \geq 2\right] .
\end{aligned}
$$

Point (ii) allows us to conclude easily.
Step 5. - It remains to check (iii). We thus fix $0 \leq s \leq t$ and $0<\ell<x$. Then as $\lambda \rightarrow 0$, and due to point (i)

$$
\begin{aligned}
\operatorname{Pr}\left[\tau / \boldsymbol{a}_{\lambda}<s, L / \boldsymbol{a}_{\lambda}>x \mid S_{t}^{\lambda}(\ell)=1\right] & =\frac{\operatorname{Pr}\left[S_{s}^{\lambda}(x)=1\right]}{\operatorname{Pr}\left[S_{t}^{\lambda}(\ell)=1\right]} \\
& \sim \frac{s \lambda \boldsymbol{a}_{\lambda} \beta x^{-\beta-1}}{t \lambda \boldsymbol{a}_{\lambda} \beta \ell^{-\beta-1}}=(s / t)(x / \ell)^{-\beta-1}
\end{aligned}
$$

3.3.2. Coupling of seeds. - We aim to couple the Poisson measure $\pi_{S}(\mathrm{~d} t, \mathrm{~d} x, \mathrm{~d} \ell)$ used to define the $\operatorname{LFF}(\beta)$-process with times/places where seeds do not fall in the $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process. We would like that roughly, $\pi_{S}\left(\{t\} \times i_{\lambda} \times\{\ell\}\right)=1$ if and only if no seed falls on $i$ during $\left[\boldsymbol{a}_{\lambda}(t-\ell), \boldsymbol{a}_{\lambda} t\right]$ (and if this is the maximal interval, that is seeds fall in $i$ at times $\boldsymbol{a}_{\lambda}(t-\ell)$ and $\left.\boldsymbol{a}_{\lambda} t\right)$. We have to consider the finite Poisson measure $\pi_{S}$ restricted to the set $\{\ell>\delta\}$, for some arbitrarily small $\delta>0$.

Proposition 3.3.3. - Let $A>0, T>0, \alpha>0$ and $\delta>0$ be fixed. For any $\lambda \in(0,1]$, it is possible to find a coupling between a Poisson measure $\pi_{S}(\mathrm{~d} t, \mathrm{~d} x, \mathrm{~d} \ell)$ on $[0, \infty) \times \mathbb{R} \times[0, \infty)$ with intensity measure $\beta(\beta+1) \ell^{-\beta-2} \mathrm{~d} t \mathrm{~d} x \mathrm{~d} \ell$ and an i.i.d. family of $\operatorname{SR}\left(\mu_{S}\right)$-processes $\left(\widetilde{T}_{n}^{i}\right)_{i \in \mathbb{Z}, n \in \mathbb{Z}}$ (recall subsection 2.1.1) in such a way that for

$$
\begin{aligned}
& S_{T}^{\lambda}(\delta, i)=\pi_{S}\left([0, T] \times i_{\lambda} \times[\delta, \infty)\right) \\
& \widetilde{S}_{T}^{\lambda}(\delta, i)=\#\left\{n \geq 1: \widetilde{T}_{n}^{i} \in\left[0, \boldsymbol{a}_{\lambda} T\right], \widetilde{T}_{n}^{i}-\widetilde{T}_{n-1}^{i} \geq \boldsymbol{a}_{\lambda} \delta\right\}
\end{aligned}
$$

setting

$$
\begin{aligned}
\Omega_{A, T, \delta, \alpha}^{S}(\lambda):=\bigcap_{i \in I_{A}^{\lambda}}\left(\{ S _ { T } ^ { \lambda } ( \delta , i ) = \widetilde { S } _ { T } ^ { \lambda } ( \delta , i ) = 0 \} \cup \left\{S_{T}^{\lambda}(\delta, i)=\widetilde{S}_{T}^{\lambda}(\delta, i)=1,\right.\right. \\
\left.\left.\left|\tau_{T}^{\lambda}(\delta, i)-\frac{\widetilde{\tau}_{T}^{\lambda}(\delta, i)}{\boldsymbol{a}_{\lambda}}\right|+\left|L_{T}^{\lambda}(\delta, i)-\frac{\widetilde{L}_{T}^{\lambda}(\delta, i)}{\boldsymbol{a}_{\lambda}}\right|<\alpha\right\}\right),
\end{aligned}
$$

there holds

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\Omega_{A, T, \delta, \alpha}^{S}(\lambda)\right)=1
$$

On the event $\left\{S_{T}^{\lambda}(\delta, i)=\widetilde{S}_{T}^{\lambda}(\delta, i)=1\right\}$, we have denoted by $\left(\tau_{T}^{\lambda}(\delta, i), L_{T}^{\lambda}(\delta, i)\right)$ the unique element $(t, \ell) \in[0, T] \times[\delta, \infty)$ such that $\pi_{S}\left(\{t\} \times i_{\lambda} \times\{\ell\}\right)=1$ and we have put $\widetilde{\tau}_{T}^{\lambda}(\delta, i)=\widetilde{T}_{n}^{i}$ and $\widetilde{L}_{T}^{\lambda}(\delta, i)=\widetilde{T}_{n}^{i}-\widetilde{T}_{n-1}^{i}$, where $n \geq 1$ is the unique element of $\mathbb{N}$ such that $\widetilde{T}_{n}^{i} \in\left[0, \boldsymbol{a}_{\lambda} T\right]$ and $\widetilde{T}_{n}^{i}-\widetilde{T}_{n-1}^{i} \geq \boldsymbol{a}_{\lambda} \delta$.

Proof. - We fix $T>0, A>0, \delta>0$ and $\alpha>0$. We divide the proof into several steps. Observe that

$$
B_{\lambda}:=\bigcup_{i \in I_{A}^{\lambda}} i_{\lambda}=\left[-A_{\lambda} / \boldsymbol{n}_{\lambda},\left(A_{\lambda}+1\right) / \boldsymbol{n}_{\lambda}\right)
$$

(which is approximately $[-A, A]$ ). It of course suffices to build $\pi_{S}$ restricted to $[0, T] \times B_{\lambda} \times[\delta, \infty)$ (we abusively still denote by $\pi_{S}$ this restriction) and the family $\left(\widetilde{T}_{n}^{i}\right)$ for $i \in I_{A}^{\lambda}$ and $n \geq 0$ (with our notation, we have $\widetilde{T}_{0}^{i} \leq 0 \leq \widetilde{T}_{1}^{i}$ ).

Step 1. - A possible way to build $\pi_{S}\left(\right.$ restricted to $\left.[0, T] \times B_{\lambda} \times[\delta, \infty)\right)$ is the following.
(i) Consider a family of i.i.d. r.v. $\left(S_{T}^{\lambda}(\delta, i)\right)_{i \in I_{A}^{\lambda}}$ following a Poisson distribution with parameter

$$
T\left|i_{\lambda}\right| \int_{\delta}^{\infty} \beta(\beta+1) \ell^{-\beta-2} \mathrm{~d} \ell=\beta \delta^{-\beta-1} T / \boldsymbol{n}_{\lambda} .
$$

(ii) For each $i \in I_{A}^{\lambda}$ with $S_{T}^{\lambda}(\delta, i)>0$, pick some i.i.d. r.v.

$$
\left\{\left(T_{k}^{i, \lambda}, X_{k}^{i, \lambda}, L_{k}^{i, \lambda}\right)\right\}_{k=1, \ldots, S_{T}^{\lambda}(\delta, i)}
$$

with density $\mathbb{1}_{\left\{t \in[0, T], x \in i_{\lambda}, \ell>\delta\right\}}(\beta+1) \boldsymbol{n}_{\lambda} \delta^{\beta+1} \ell^{-\beta-2} / T$. Put

$$
\pi_{S}=\sum_{i \in I_{A}^{\lambda}} \sum_{k=1}^{S_{T}^{\lambda}(\delta, i)} \delta_{\left(T_{k}^{i, \lambda}, X_{k}^{i, \lambda}, L_{k}^{i, \lambda}\right)} .
$$

Step 2. - Next, we note it is possible to build the family $\left(\widetilde{T}_{n}^{i}\right)_{i \in I_{A}^{\lambda}, n \geq 0}$ as follows: denote by $q_{k}(\lambda)=\operatorname{Pr}\left[\widetilde{S}_{T}^{\lambda}(\delta, i)=k\right]$ and by $\Lambda_{k}^{\lambda}$ the law of $\left(\widetilde{T}_{n}^{i}\right)_{n \geq 0}$ conditionally on $\left\{\widetilde{S}_{T}^{\lambda}(\delta, i)=k\right\}$.
(i) Consider a family of i.i.d. r.v. $\left(\widetilde{S}_{T}^{\lambda}(\delta, i)\right)_{i \in I_{A}^{\lambda}}$ with law $\left(q_{k}(\lambda)\right)_{k \geq 0}$.
(ii) For each $i \in I_{A}^{\lambda}$, pick $\left(\widetilde{T}_{n}^{i}\right)_{n \geq 0}$ according to $\Lambda_{\widetilde{S}_{T}^{\lambda}(\delta, i)}^{\lambda}$ (conditionally on $\left.\widetilde{S}_{T}^{\lambda}(\delta, i)\right)$.

Step 3. - For each $i$, it is possible to couple $S_{T}^{\lambda}(\delta, i)$ and $\widetilde{S}_{T}^{\lambda}(\delta, i)$, distributed as in step 1 (i) and step 2 (i), in such a way that

$$
\begin{aligned}
& \operatorname{Pr}\left[S_{T}^{\lambda}(\delta, i)=\widetilde{S}_{T}^{\lambda}(\delta, i)=0\right] \geq 1-\lambda \boldsymbol{a}_{\lambda} \beta \delta^{-\beta-1} T\left(1+\varepsilon_{T, \delta}(\lambda)\right), \\
& \operatorname{Pr}\left[S_{T}^{\lambda}(\delta, i)=\widetilde{S}_{T}^{\lambda}(\delta, i)=1\right] \geq \lambda \boldsymbol{a}_{\lambda} \beta \delta^{-\beta-1} T\left(1-\varepsilon_{T, \delta}(\lambda)\right),
\end{aligned}
$$

where $\lim _{\lambda \rightarrow 0} \varepsilon_{T, \delta}(\lambda)=0$. It is classically possible (see Lemma 5.1 .3 (i)) to build a coupling in such a way that

$$
\begin{aligned}
& \operatorname{Pr}\left[S_{T}^{\lambda}(\delta, i)=\widetilde{S}_{T}^{\lambda}(\delta, i)=0\right] \geq \operatorname{Pr}\left(S_{T}^{\lambda}(\delta, i)=0\right) \wedge \operatorname{Pr}\left(\widetilde{S}_{T}^{\lambda}(\delta, i)=0\right), \\
& \operatorname{Pr}\left[S_{T}^{\lambda}(\delta, i)=\widetilde{S}_{T}^{\lambda}(\delta, i)=1\right] \geq \operatorname{Pr}\left(S_{T}^{\lambda}(\delta, i)=1\right) \wedge \operatorname{Pr}\left(\widetilde{S}_{T}^{\lambda}(\delta, i)=1\right) .
\end{aligned}
$$

First, we infer from Lemma 3.3.2 that

$$
\begin{array}{r}
\operatorname{Pr}\left(\widetilde{S}_{T}^{\lambda}(\delta, i)=0\right) \geq 1-\lambda \boldsymbol{a}_{\lambda} \beta \delta^{-\beta-1} T\left(1+\varepsilon_{T, \delta}(\lambda)\right), \\
\quad \operatorname{Pr}\left(\widetilde{S}_{T}^{\lambda}(\delta, i)=1\right) \geq \lambda \boldsymbol{a}_{\lambda} \beta \delta^{-\beta-1} T\left(1-\varepsilon_{T, \delta}(\lambda)\right) .
\end{array}
$$

Next, since $S_{T}^{\lambda}(\delta, i)$ follows a Poisson distribution with parameter $\beta \delta^{-\beta-1} T / \boldsymbol{n}_{\lambda} \sim$ $\lambda \boldsymbol{a}_{\lambda} \beta \delta^{-\beta-1} T$, we have

$$
\operatorname{Pr}\left(S_{T}^{\lambda}(\delta, i)=0\right)=\mathrm{e}^{-\beta \delta^{-\beta-1} T / \boldsymbol{n}_{\lambda}} \geq 1-\lambda \boldsymbol{a}_{\lambda} \beta \delta^{-\beta-1} T\left(1+\varepsilon_{T, \delta}(\lambda)\right)
$$

and there holds

$$
\operatorname{Pr}\left(S_{T}^{\lambda}(\delta, i)=1\right)=\left[\beta \delta^{-\beta-1} T / \boldsymbol{n}_{\lambda}\right] \mathrm{e}^{-\beta \delta^{-\beta-1} T / \boldsymbol{n}_{\lambda}} \geq \lambda \boldsymbol{a}_{\lambda} \beta \delta^{-\beta-1} T\left(1-\varepsilon_{T, \delta}(\lambda)\right)
$$

This concludes the step.
Step 4. - We now check that for each $i \in I_{A}^{\lambda}$, conditionally on

$$
\left\{S_{T}^{\lambda}(\delta, i)=\widetilde{S}_{T}^{\lambda}(\delta, i)=1\right\}
$$

we can couple $\left(T_{1}^{i, \lambda}, L_{1}^{i, \lambda}, X^{i, \lambda, 1}\right)$ and $\left(\widetilde{T}_{n}^{i}\right)_{n \geq 0}$ in such a way that $\lim _{\lambda \rightarrow 0} r_{T, \delta, \alpha}(\lambda)=1$ for (see the statement)

$$
r_{T, \delta, \alpha}(\lambda)=\operatorname{Pr}\left[\left.\left|\tau_{T}^{\lambda}(\delta, i)-\frac{\widetilde{\tau}_{T}^{\lambda}(\delta, i)}{\boldsymbol{a}_{\lambda}}\right|+\left|L_{T}^{\lambda}(\delta, i)-\frac{\widetilde{L}_{T}^{\lambda}(\delta, i)}{\boldsymbol{a}_{\lambda}}\right|<\alpha \right\rvert\, Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda}=1\right] .
$$

To this end, consider $\left(\widetilde{T}_{n}^{i}\right)_{n \geq 0}$ with law $\Lambda_{1}^{\lambda}$ (recall step 2). Denote by

$$
p_{\delta, T}^{\lambda}(\mathrm{d} t, \mathrm{~d} \ell)
$$

the law of $\left(\widetilde{\tau}_{T}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda}, \widetilde{L}_{T}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda}\right)$ (under $\left.\Lambda_{1}^{\lambda}\right)$. We know from Lemma 3.3.2 (iii) that $p_{\delta, T}^{\lambda}(\mathrm{d} t, \mathrm{~d} \ell)$ goes weakly, as $\lambda \rightarrow 0$, to

$$
p_{\delta, T}(\mathrm{~d} t, \mathrm{~d} \ell):=T^{-1}(\beta+1) \delta^{\beta+1} \ell^{-\beta-2} \mathbb{1}_{\{t \in[0, T], l \geq \delta\}} \mathrm{d} t \mathrm{~d} \ell
$$

Indeed, observe that $p_{\delta, T}([0, s] \times[x, \infty))=(s / T)(x / \delta)^{-\beta-1}$ for $s \in[0, T]$ and $x>\delta$.
But $p_{\delta, T}(\mathrm{~d} t, \mathrm{~d} \ell)$ is nothing but the law of $\left(\tau_{T}^{\lambda}(\delta, i), L_{T}^{\lambda}(\delta, i)\right)=\left(T_{1}^{i, \lambda}, L_{1}^{i, \lambda}\right)$ conditionally on $\left\{S_{T}^{\lambda}(\delta, i)=1\right\}$ (recall step 1 (ii)). We easily conclude: first, we couple $\left(\widetilde{\tau}_{T}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda}, \widetilde{L}_{T}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda}\right)$ and $\left(\tau_{T}^{\lambda}(\delta, i), L_{T}^{\lambda}(\delta, i)\right)$ in such a way that they are close to each other (with a distance smaller than $\alpha$ ) with high probability (tending to 1 when $\lambda \rightarrow 0$ ), using Lemma 5.1.3 (iii). Then we choose $X_{1}^{i, \lambda}$ at random, uniformly in $i_{\lambda}$, independently of everything else and finally, we pick $\left(\widetilde{T}_{n}^{i}\right)_{n \geq 0}$ conditionally on $\left\{\widetilde{S}_{T}^{\lambda}(\delta, i)=1\right\}$ and $\left(\widetilde{\tau}_{T}^{\lambda}(\delta, i), \widetilde{L}_{T}^{\lambda}(\delta, i)\right)$.

Step 5. - We finally may build the complete coupling.
(i) For each $i \in I_{A}^{\lambda}$, consider some coupled r.v. $\left(S_{T}^{\lambda}(\delta, i), \widetilde{S}_{T}^{\lambda}(\delta, i)\right)$ as in step 3.
(ii) For $i \in I_{A}^{\lambda}$ such that $S_{T}^{\lambda}(\delta, i)=\widetilde{S}_{T}^{\lambda}(\delta, i)=1$, couple $\left(T_{1}^{i, \lambda}, L_{1}^{i, \lambda}, X_{1}^{i, \lambda}\right)$ and $\left(\widetilde{T}_{n}^{i}\right)_{n \geq 0}$ as in step 4.
(iii) For $i \in I_{A}^{\lambda}$ not meeting the above condition (ii), follow the rules of step 1 (ii) to build $\left(T_{k}^{i, \lambda}, X_{k}^{i, \lambda}, L_{k}^{i, \lambda}\right)_{1 \leq k \leq S_{T}^{\lambda}(\delta, i)}$ and the rules of step 2 (ii) to build $\left\{\widetilde{T}_{n}^{i}\right\}_{n \geq 0}$ (e.g. independently).

This defines $\left\{\widetilde{T}_{n}^{i}\right\}_{n \geq 0, i \in I_{A}^{\lambda}}$ and $\pi_{S}:=\sum_{i \in I_{A}^{\lambda}} \sum_{k=1}^{S_{T}^{\lambda}(\delta, i)} \delta_{\left(T_{k}^{i, \lambda}, X_{k}^{i, \lambda}, L_{k}^{i, \lambda}\right)}$.
Step 6. - With this coupling, using steps 3 and 4 and that $\left|I_{A}^{\lambda}\right|=2 A_{\lambda}+1$,

$$
\begin{aligned}
& \operatorname{Pr}\left[\Omega_{A, T, \delta, \alpha}^{S}\right] \\
& \quad \geq\left(\operatorname{Pr}\left[S_{T}^{\lambda}(\delta, i)=\widetilde{S}_{T}^{\lambda}(\delta, i)=0\right]+\operatorname{Pr}\left[S_{T}^{\lambda}(\delta, i)=\widetilde{S}_{T}^{\lambda}(\delta, i)=1,\right.\right. \\
& \left.\left.\quad\left|\tau_{T}^{\lambda}(\delta, i)-\widetilde{\tau}_{T}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda}\right|+L_{T}^{\lambda}(\delta, i)-\widetilde{L}_{T}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda} \mid<\alpha\right]\right)^{2 A_{\lambda}+1} \\
& \quad \geq\left(1-\lambda \boldsymbol{a}_{\lambda} \beta \delta^{\beta-1} T\left(1+\varepsilon_{T, \delta}(\lambda)\right)+\lambda \boldsymbol{a}_{\lambda} \beta \delta^{\beta-1} T\left(1-\varepsilon_{T, \delta}(\lambda)\right) r_{T, \delta, \alpha}(\lambda)\right)^{2 A_{\lambda}+1}
\end{aligned}
$$

Recall that $\lim _{\lambda \rightarrow 0} \varepsilon_{T, \delta}(\lambda)=0$, that $\lim _{\lambda \rightarrow 0} r_{T, \delta, \alpha}(\lambda)=1$ and that $A_{\lambda} \leq A /\left(\lambda \boldsymbol{a}_{\lambda}\right)$. Hence for some function $\varepsilon_{T, \delta, \alpha}$ with limit 0 at 0 ,

$$
\operatorname{Pr}\left[\Omega_{A, T, \delta, \alpha}^{S}\right] \geq\left(1-\lambda \boldsymbol{a}_{\lambda} \beta \delta^{\beta-1} T \varepsilon_{T, \delta, \alpha}(\lambda)\right)^{2 A /\left(\lambda \boldsymbol{a}_{\lambda}\right)+1}
$$

This last quantity tends to 1 as $\lambda \rightarrow 0$, which concludes the proof.
3.3.3. Convergence. - We are now able to conclude. Intuitively, the situation is clear: using Proposition 3.2.1, we couple the time/positions at which matches fall in the $\operatorname{LFF}(\beta)$-process with those of the $\mathrm{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process; and using Proposition 3.3.3, we couple the time/positions at which no seed fall in the $\operatorname{LFF}(\beta)$-process with time/positions at which no seed fall during a time interval of length of order $\boldsymbol{a}_{\lambda}$ in the $\mathrm{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process. Then we only have to show carefully that this is sufficient to couple the $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process and the $\operatorname{LFF}(\beta)$-process in such a way that they remain close to each other. But there are many technical problems: our couplings concern only finite boxes $[0, T] \times[-A, A]$, do not allow to treat small time intervals with no seed falling, etc. We thus have to localize the processes in space and time and to work on an event (with high probability) on which everything works as desired.

Proof of Theorem 2.5.3. - We fix $T>0, x_{1}<\cdots<x_{p}$ and $t_{1}, \ldots, t_{p} \in[0, T]$. We introduce $B>0$ such that $-B<x_{1}<x_{p}<B$. We fix $\varepsilon>0$ and $a>0$. Our aim is to check that for all $\lambda>0$ small enough, there exists a coupling between a $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ and a LFF $(\beta)$-process $\left(Y_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ such that, recalling (2.2.3) and Proposition 2.5.2,

$$
\begin{equation*}
\operatorname{Pr}\left[\sum_{k=1}^{p} \boldsymbol{\delta}_{T}\left(D^{\lambda}\left(x_{k}\right), D\left(x_{k}\right)\right)+\sum_{k=1}^{p} \boldsymbol{\delta}\left(D_{t_{k}}^{\lambda}\left(x_{k}\right), D_{t_{k}}\left(x_{k}\right)\right) \geq a\right] \leq \varepsilon . \tag{3.3.1}
\end{equation*}
$$

This will of course conclude the proof.
Step 1. - Consider two independent Poisson measures $\pi_{S}(\mathrm{~d} t, \mathrm{~d} x, \mathrm{~d} \ell)$ with intensity measure $\beta(\beta+1) \ell^{-\beta-2} \mathrm{~d} t \mathrm{~d} x \mathrm{~d} \ell$ and $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)$ with intensity measure $\mathrm{d} t \mathrm{~d} x$. Set, for $A>B$,

$$
\begin{aligned}
\Omega_{A, T}^{S, 1} & :=\left\{\pi_{S}(\{(t, x, \ell): x \in[B, A], t>T+1, \ell>t+1\})>0\right\} \\
& \cap\left\{\pi_{S}(\{(t, x, \ell): x \in[-A,-B], t>T+1, \ell>t+1\})>0\right\}
\end{aligned}
$$

A simple computation shows that

$$
\operatorname{Pr}\left[\Omega_{A, T}^{S, 1}\right] \geq 1-2 \exp \left(-\int_{B}^{A} \mathrm{~d} x \int_{T+1}^{\infty} \mathrm{d} t \int_{t+1}^{\infty} \beta(\beta+1) \ell^{-\beta-2}\right)
$$

so that we can choose $A$ large enough in such a way that $\operatorname{Pr}\left[\Omega_{A, T}^{S, 1}\right] \geq 1-\frac{1}{6} \varepsilon$. This will ensure us that there are $\chi_{g} \in[-A,-B]$ and $\chi_{d} \in[A, B]$ with $Y_{t}\left(\chi_{g}\right)=Y_{t}\left(\chi_{d}\right)=0$ for all $t \in[0, T+1]$ (recall Figure 4). This fixes the value of $A$ for the whole proof.

Next we consider $T_{0}>T+1$ large enough, so that for

$$
\Omega_{A, T, T_{0}}^{S, 2}=\left\{\pi_{S}\left(\left\{(t, x, \ell): t>T_{0}, t-\ell<T+1, x \in[-A, A]\right\}\right)=0\right\}
$$

$\operatorname{Pr}\left[\Omega_{A, T, T_{0}}^{S, 2}\right] \geq 1-\frac{1}{6} \varepsilon$. This is possible, because

$$
\operatorname{Pr}\left[\Omega_{A, T, T_{0}}^{S, 2}\right]=\exp \left(-\int_{-A}^{A} \mathrm{~d} x \int_{T_{0}}^{\infty} \mathrm{d} t \int_{t-(T+1)}^{\infty} \beta(\beta+1) \ell^{-\beta-2} \mathrm{~d} \ell\right)
$$

which clearly tends to 1 as $T_{0}$ increases to infinity. This will ensure us that all the dotted vertical segments in $[-A, A]$ that intersect $[0, T+1]$ end before $T_{0}$ (see Figure 4). This fixes the value of $T_{0}$ for the whole proof. Next we call

$$
\begin{aligned}
\mathcal{X}_{M} & =\left\{x \in[-A, A]: \pi_{M}([0, T] \times\{x\})>0\right\}, \\
\mathcal{T}_{M} & =\left\{t \in[0, T]: \pi_{M}(\{t\} \times[-A, A])>0\right\} \cup\{0\} .
\end{aligned}
$$

Classical results about Poisson measures allow us to choose $K_{M}>0$ (large) and $c_{M}>0$ (small) in such a way that $\operatorname{Pr}\left[\Omega_{K_{M}, c_{M}}^{M, 1}\right] \geq 1-\frac{1}{6} \varepsilon$ for

$$
\Omega_{K_{M}, c_{M}}^{M, 1}=\left\{\left|\mathcal{T}_{M}\right| \leq K_{M}, \min _{\substack{t, s \in \mathcal{T}_{M} \\ s \neq t}}|t-s|>c_{M}, \min _{\substack{t \in \mathcal{T}_{M} \\ k=1, \ldots, p}}\left|t-t_{k}\right|>c_{M}, \min _{\substack{x \in \mathcal{X}_{M} \\ k=1, \ldots, p}}\left|x-x_{k}\right|>c_{M}\right\} .
$$

We can now fix $\delta>0$ for the whole proof, in such a way that

$$
\delta<\frac{1}{4} c_{M} \quad \text { and } \quad \delta<\frac{a}{8 A p K_{M}} .
$$

We use this $\delta$ to cutoff the Poisson measure $\pi_{S}$ (in order that it has only a finite number of marks) without affecting the values of the $\operatorname{LFF}(\beta)$-process in the zone under study.

Next, we consider the finite Poisson measure $\pi_{S}^{A, \delta, T_{0}}$ defined as the restriction of $\pi_{S}$ to the set $\left[0, T_{0}\right] \times[-A, A] \times[\delta, \infty)$. We define

$$
\begin{aligned}
\mathcal{X}_{S}^{\delta} & =\left\{x \in[-A, A]: \pi_{S}\left(\left[0, T_{0}\right] \times\{x\} \times[\delta, \infty)\right)>0\right\}, \\
\mathcal{T}_{S}^{\delta} & =\left(\bigcup_{(t, x, \ell) \in \operatorname{supp} \pi_{S}^{A, \delta, T_{0}}}\{t, t-\ell\}\right) \cap[0, T] .
\end{aligned}
$$

Then for $K_{S}>0$ large enough and $c_{S}>0$ small enough, the event

$$
\begin{aligned}
& \Omega_{K_{S}, c_{S}, \delta}^{S, 3}=\left\{\left|\mathcal{T}_{S}^{\delta}\right| \leq K_{S}, \min _{\substack{t \in \mathcal{T}_{M} \\
s \in \mathcal{T}_{S}^{\delta}}}^{|t-s|} \mid>c_{S}, \min _{\substack{t \in \mathcal{T}_{S}^{\delta} \\
k=1, \ldots, p}}>c_{S},\right. \\
& \left.\min _{\substack{x, y \in \mathcal{X}_{S}^{\delta} \\
x \neq y}}>c_{S}, \min _{\substack{x \in \mathcal{X}_{S}^{\delta} \\
y \in \mathcal{X}_{M}}}>c_{S}, \min _{\substack{x \in \mathcal{X}_{S}^{\delta} \\
k=1, \ldots, p}}>c_{S}\right\}
\end{aligned}
$$

satisfies $\operatorname{Pr}\left[\Omega_{K_{S}, c_{S}, \delta}^{S, 3}\right] \geq 1-\frac{1}{6} \varepsilon$. Finally, we fix $\alpha>0$ in such a way that

$$
\alpha<\frac{1}{4} c_{S}, \quad \alpha<\frac{1}{4} c_{M}, \quad \alpha<\frac{1}{2} \quad \text { and } \quad \alpha<a /\left(8 A p\left(2 K_{S}+K_{M}\right)\right) .
$$

Step 2. - Using Proposition 3.2.1, we know that for all $\lambda>0 \mathrm{small}$ enough, it is possible to couple a family of i.i.d. $\mathrm{SR}\left(\mu_{M}^{\lambda}\right)$-processes $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ with $\pi_{M}$ in such a way that

$$
\Omega_{A, T}^{M}(\lambda):=\left\{\forall t \in[0, T], \forall i \in I_{A}^{\lambda}, \Delta N_{a_{\lambda} t}^{M, \lambda}(i) \neq 0 \text { iff } \pi_{M}\left(\{t\} \times i_{\lambda}\right) \neq 0\right\}
$$

satisfies $\operatorname{Pr}\left[\Omega_{A, T}^{M}(\lambda)\right] \geq 1-\frac{1}{6} \varepsilon$. We infer from Proposition 3.3.3 that for all $\lambda>0$ small enough, it is possible to couple an i.i.d. family of $\operatorname{SR}\left(\mu_{S}\right)$-processes $\left(\widetilde{T}_{n}^{i}\right)_{i \in \mathbb{Z}, n \geq 0}$ with $\pi_{S}$ in such a way that for

$$
\begin{aligned}
& S_{T_{0}}^{\lambda}(\delta, i)=\pi_{S}\left(\left[0, T_{0}\right] \times\left\{i_{\lambda}\right\} \times[\delta, \infty)\right), \\
& \widetilde{S}_{T_{0}}^{\lambda}(\delta, i)=\#\left\{n \geq 1: \widetilde{T}_{n}^{i} \in\left[0, \boldsymbol{a}_{\lambda} T_{0}\right], \widetilde{T}_{n}^{i}-\widetilde{T}_{n-1}^{i} \geq \boldsymbol{a}_{\lambda} \delta\right\},
\end{aligned}
$$

setting

$$
\begin{array}{r}
\Omega_{A, T_{0}, \delta, \alpha}^{S}(\lambda):=\bigcap_{i \in I_{A}^{\lambda}}\left(\{ S _ { T _ { 0 } } ^ { \lambda } ( \delta , i ) = \widetilde { S } _ { T _ { 0 } } ^ { \lambda } ( \delta , i ) = 0 \} \cup \left\{S_{T_{0}}^{\lambda}(\delta, i)=\widetilde{S}_{T_{0}}^{\lambda}(\delta, i)=1,\right.\right. \\
\left.\left.\left|\tau^{\lambda}(\delta, i)-\frac{\widetilde{\tau}^{\lambda}(\delta, i)}{\boldsymbol{a}_{\lambda}}\right|+\left|L^{\lambda}(\delta, i)-\frac{\widetilde{L}^{\lambda}(\delta, i)}{\boldsymbol{a}_{\lambda}}\right|<\alpha\right\}\right),
\end{array}
$$

$\operatorname{Pr}\left(\Omega_{A, T_{0}, \delta, \alpha}^{S}(\lambda)\right) \geq 1-\frac{1}{6} \varepsilon$. On the event $\left\{S_{T_{0}}^{\lambda}(\delta, i)=\widetilde{S}_{T_{0}}^{\lambda}(\delta, i)=1\right\}$, we have denoted by $\left(\tau^{\lambda}(\delta, i), L^{\lambda}(\delta, i)\right)$ the unique element $(t, \ell) \in\left[0, T_{0}\right] \times[\delta, \infty)$ such that $\pi_{S}\left(\{t\} \times i_{\lambda} \times\{\ell\}\right)=1$ and we have put

$$
\widetilde{\tau}^{\lambda}(\delta, i)=\widetilde{T}_{n}^{i} \quad \text { and } \quad \widetilde{L}^{\lambda}(\delta, i)=\widetilde{T}_{n}^{i}-\widetilde{T}_{n-1}^{i}
$$

where $n \geq 1$ is the unique element of $\mathbb{N}$ such that $\widetilde{T}_{n}^{i} \in\left[0, \boldsymbol{a}_{\lambda} T_{0}\right]$ and $\widetilde{T}_{n}^{i}-\widetilde{T}_{n-1}^{i} \geq \boldsymbol{a}_{\lambda} \delta$. We put

$$
N_{t}^{S}(i)=\sum_{n \geq 1} \mathbb{1}_{\left\{\widetilde{T}_{n}^{i} \geq t\right\}}
$$

for all $i \in \mathbb{Z}$, all $t \geq 0$, which is a family of i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes in the sense of Definition 2.1.1, see subsection 2.1.1.

Step 3. - We work with the $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ built from $\left(N_{t}^{S}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ and $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ and the LFF $(\beta)$-process $\left(Y_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ built from $\pi_{S}$ and $\pi_{M}$, all these processes being coupled as in step 2 . We consider the associated clusters $\left(D_{t}^{\lambda}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ and $\left(D_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$, see (2.2.3) and Proposition 2.5.2. We will work on the event

$$
\Omega_{\lambda}=\Omega_{A, T}^{S, 1} \cap \Omega_{A, T, T_{0}}^{S, 2} \cap \Omega_{K_{M}, c_{M}}^{M, 1} \cap \Omega_{K_{S}, c_{S}, \delta}^{S, 3} \cap \Omega_{A, T}^{M}(\lambda) \cap \Omega_{A, T_{0}, \delta, \alpha}^{S}(\lambda) .
$$

Thanks to the previous steps, we know that $\operatorname{Pr}\left[\Omega_{\lambda}\right] \geq 1-\varepsilon$ for all $\lambda>0$ small enough. We introduce

$$
\mathcal{S}=\left(\cup_{t \in \mathcal{T}_{M}}[t, t+\delta+\alpha]\right) \cup\left(\cup_{t \in \mathcal{T}_{S}^{\delta}}[t-\alpha, t+\alpha]\right)
$$

We will prove in the next steps that for $\lambda>0$ small enough, on $\Omega_{\lambda}$, for all $k=1, \ldots, p$, for all $t \in[0, T]$,

$$
\begin{equation*}
\boldsymbol{\delta}\left(D_{t}^{\lambda}\left(x_{k}\right), D_{t}\left(x_{k}\right)\right) \leq 4 / \boldsymbol{n}_{\lambda}+2 A \mathbb{1}_{\{t \in \mathcal{S}\}}, \tag{3.3.2}
\end{equation*}
$$

which will imply that

$$
\boldsymbol{\delta}_{T}\left(D^{\lambda}\left(x_{k}\right), D\left(x_{k}\right)\right) \leq 4 T / \boldsymbol{n}_{\lambda}+2 A|\mathcal{S}| .
$$

This will conclude the proof. Indeed, on $\Omega_{\lambda}$, we know that $t_{1}, \ldots, t_{p}$ do not belong to $\mathcal{S}$ (thanks to $\Omega_{K_{S}, c_{S}, \delta}^{S, 3}$ and $\Omega_{K_{M}, c_{M}}^{M, 1}$ and since $c_{S}>\alpha$ and $c_{M}>\delta+\alpha$ ) and that
the Lebesgue measure of $\mathcal{S}$ is smaller than $K_{M} \delta+\left(2 K_{S}+K_{M}\right) \alpha$. Thus on $\Omega_{\lambda}$, since $\delta<a /\left(8 A p K_{M}\right)$ and $\alpha<a /\left(8 A p\left(2 K_{S}+K_{M}\right)\right)$,

$$
\begin{aligned}
& \sum_{k=1}^{p} \boldsymbol{\delta}_{T}\left(D^{\lambda}\left(x_{k}\right), D\left(x_{k}\right)\right)+\sum_{k=1}^{p} \boldsymbol{\delta}\left(D_{t_{k}}^{\lambda}\left(x_{k}\right), D_{t_{k}}\left(x_{k}\right)\right) \\
& \quad \leq p\left[2 A\left(K_{M} \delta+\left(2 K_{S}+K_{M}\right) \alpha\right)+4 T / \boldsymbol{n}_{\lambda}+4 / \boldsymbol{n}_{\lambda}\right] \leq a / 2+(4 T+4) p / \boldsymbol{n}_{\lambda}
\end{aligned}
$$

which is smaller than $a$ for all $\lambda>0$ small enough. This implies (3.3.1) for all $\lambda>0$ small enough.

Step 4. - Here we localize the processes, on the event $\Omega_{\lambda}$. Due to $\Omega_{A, T}^{S, 1}$, we know that $\pi_{S}$ has some marks $\left(\tau_{g}, \chi_{g}, L_{g}\right)$ and $\left(\tau_{d}, \chi_{d}, L_{d}\right)$ such that $-A<\chi_{g}<$ $-B, B<\chi_{d}<A, \tau_{g}>T+1, \tau_{d}>T+1, L_{g}>\tau_{g}+1$ and $L_{d}>\tau_{d}+1$. This implies, by definition of the $\operatorname{LFF}(\beta)$-process, that $Y_{t}\left(\chi_{g}\right)=Y_{t}\left(\chi_{d}\right)=0$ for all $t \in$ $[0, T+1]$. Consequently, for all $t \in[0, T]$ and all $x \in\left[\chi_{g}, \chi_{d}\right] \supset[-B, B]$, we have $D_{t}(x) \subset\left[\chi_{g}, \chi_{d}\right]$.

Set now $g_{\lambda}=\left\lfloor\boldsymbol{n}_{\lambda} \chi_{g}\right\rfloor$ and $d_{\lambda}=\left\lfloor\boldsymbol{n}_{\lambda} \chi_{d}\right\rfloor$. These are those sites of $I_{A}^{\lambda} \subset \mathbb{Z}$ such that $\chi_{g} \in\left(g_{\lambda}\right)_{\lambda}$ and $\chi_{d} \in\left(d_{\lambda}\right)_{\lambda}$. We claim that on $\Omega_{\lambda}$, for all $t \in\left[0, a_{\lambda} T\right]$,

$$
\eta_{t}^{\lambda}\left(g_{\lambda}\right)=\eta_{t}^{\lambda}\left(d_{\lambda}\right)=0
$$

Consequently on $\Omega_{\lambda}$, we clearly have $C\left(\eta_{a_{\lambda} t}^{\lambda}, i\right) \subset \llbracket g_{\lambda}+1, d_{\lambda}-1 \rrbracket$ for all $t \in[0, T]$ and all $i \in \llbracket g_{\lambda}+1, d_{\lambda}-1 \rrbracket$.

Indeed, consider e.g. the case of $d_{\lambda}$. Due to $\Omega_{A, T_{0}, \delta, \alpha}^{S}(\lambda)$ and since $S_{T_{0}}^{\lambda}\left(\delta, d_{\lambda}\right)>0$ (because $\pi_{S}$ has the mark $\left(\tau_{d}, \chi_{d}, L_{d}\right)$ that falls in $\left[0, T_{0}\right] \times\left(d_{\lambda}\right)_{\lambda} \times[\delta, \infty)$ ), we deduce that $S_{T_{0}}^{\lambda}\left(\delta, d_{\lambda}\right)=\widetilde{S}_{T_{0}}^{\lambda}\left(\delta, d_{\lambda}\right)=1$ and that

$$
\left|\widetilde{\tau}^{\lambda}\left(\delta, d_{\lambda}\right) / \boldsymbol{a}_{\lambda}-\tau_{d}\right|+\left|\widetilde{L}^{\lambda}\left(\delta, d_{\lambda}\right) / \boldsymbol{a}_{\lambda}-L_{d}\right|<\alpha<1
$$

But no seed falls on $d_{\lambda}$, by definition, during $\left(\widetilde{\tau}^{\lambda}\left(\delta, d_{\lambda}\right)-\widetilde{L}^{\lambda}\left(\delta, d_{\lambda}\right), \widetilde{\tau}^{\lambda}\left(\delta, d_{\lambda}\right)\right)$. This last interval contains $\left[0, \boldsymbol{a}_{\lambda} T\right]$ : since $\alpha<\frac{1}{2}, \widetilde{\tau}^{\lambda}\left(\delta, d_{\lambda}\right) \geq \boldsymbol{a}_{\lambda}\left(\tau_{d}-\alpha\right) \geq \boldsymbol{a}_{\lambda}(T+1-\alpha)>\boldsymbol{a}_{\lambda} T$ and $\widetilde{\tau}^{\lambda}\left(\delta, d_{\lambda}\right)-\widetilde{L}^{\lambda}\left(\delta, d_{\lambda}\right) \leq \boldsymbol{a}_{\lambda}\left(\tau_{d}-L_{d}+2 \alpha\right) \leq \boldsymbol{a}_{\lambda}(-1+2 \alpha)<0$. This proves that $\eta_{t}^{\lambda}\left(d_{\lambda}\right)=0$ for all $t \in\left[0, a_{\lambda} T\right]$.

Using furthermore $\Omega_{A, T, T_{0}}^{S, 2}(0)$, we deduce that on $\Omega_{\lambda},\left(Y_{t}(x), D_{t}(x)\right)_{t \in[0, T], x \in\left[\chi_{g}, \chi_{d}\right]}$ is completely determined by the values of $\pi_{S}$ and $\pi_{M}$ restricted to the boxes $\left[0, T_{0}\right] \times$ $\left[\chi_{g}, \chi_{d}\right] \times(0, \infty)$ and $[0, T] \times\left[\chi_{g}, \chi_{d}\right]$. By the same way, $\left(\eta_{t}^{\lambda}(i)\right)_{t \in\left[0, a_{\lambda} T\right], i \in \llbracket g_{\lambda}, d_{\lambda} \rrbracket}$ is completely determined by $\left(N_{t}^{S}(i), N_{t}^{M, \lambda}(i)\right)_{t \in\left[0, a_{\lambda} T\right], i \in \llbracket g_{\lambda}, d_{\lambda} \rrbracket}$. And we recall that $[-B, B] \subset\left[\chi_{g}, \chi_{d}\right] \subset[-A, A]$.

Step 5. - In this whole step, we work on $\Omega_{\lambda}$. We denote by $\left(\rho_{i}, \alpha_{i}\right)_{i=1, \ldots, n}$ the marks of $\pi_{M}$ in $[0, T] \times\left[\chi_{g}, \chi_{d}\right]$, ordered chronologically $\left(0=\rho_{0}<\rho_{1}<\cdots<\rho_{n}<T\right)$. For each $k$, we recall that in the $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process, there is match falling at time $\boldsymbol{a}_{\lambda} \rho_{k}$ on the site $\left\lfloor\boldsymbol{n}_{\lambda} \alpha_{k}\right\rfloor$ (recall $\Omega_{A, T}^{M}(\lambda)$ and that $x \in i_{\lambda}$ iff $i=\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor$ ). Furthermore, these are the only fires in $\left[0, \boldsymbol{a}_{\lambda} T\right] \times \llbracket g_{\lambda}, d_{\lambda} \rrbracket$. For $k=0, \ldots, n$, let us consider the
properties

$$
\begin{aligned}
& \left(H_{k}\right): \quad \forall i \in \llbracket g_{\lambda}, d_{\lambda} \rrbracket, \quad \eta_{a_{\lambda} \rho_{k}}^{\lambda}(i)=\inf _{x \in i_{\lambda}} Y_{\rho_{k}}(x) ; \\
& \left(H_{k}^{*}\right): \quad \forall i \in \llbracket g_{\lambda}, d_{\lambda} \rrbracket, \forall t \in\left[\rho_{k}, \rho_{k+1}\right) \backslash \mathcal{S}, \quad \eta_{a_{\lambda} t}^{\lambda}(i)=\inf _{x \in i_{\lambda}} Y_{t}(x) .
\end{aligned}
$$

We observe that $\left(H_{0}\right)$ holds: for any $i \in \mathbb{Z}, \eta_{0}^{\lambda}(i)=0$ and $\inf _{x \in i_{\lambda}} Y_{0}(x)=0$ because the set $\left\{x \in \mathbb{R}: Y_{0}(x)=0\right\}$ is a.s. dense in $\mathbb{R}$. Indeed, recall that $Y_{0}(x)=0$ as soon as $\pi_{S}(\{(t, x, \ell): l>t\})>0$ and that $\int_{0}^{\infty} \mathrm{d} t \int_{t}^{\infty} \beta(\beta+1) \ell^{-\beta-2} \mathrm{~d} \ell=\infty$.

We are going to prove that for $k \in\{0, \ldots, n-1\},\left(H_{k}\right)$ implies $\left(H_{k}^{*}\right)$ and $\left(H_{k+1}\right)$. Assume thus that $\left(H_{k}\right)$ holds for some $k \in\{0, \ldots, n-1\}$.

We first prove that $\left(H_{k}^{*}\right)$ holds.
We recall that for all $i \in \llbracket g_{\lambda}, d_{\lambda} \rrbracket, S_{T_{0}}^{\lambda}(\delta, i)=\widetilde{S}_{T_{0}}^{\lambda}(\delta, i)$ is either 0 or 1 . On $\left\{S_{T_{0}}^{\lambda}(\delta, i)=\widetilde{S}_{T_{0}}^{\lambda}(\delta, i)=1\right\}$, we have

$$
\left|\tau^{\lambda}(\delta, i)-\widetilde{\tau}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda}\right|<\alpha \quad \text { and } \quad\left|L^{\lambda}(\delta, i)-\widetilde{L}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda}\right|<\alpha
$$

Recalling furthermore $\Omega_{K_{M}, c_{M}}^{M, 1}$ and $\Omega_{K_{S}, c_{S}, \delta}^{S, 3}$, using that $\alpha<\frac{1}{4} c_{M}$, we deduce that: $\triangleright$ either $\tau^{\lambda}(\delta, i)$ and $\widetilde{\tau}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda}$ both belong to the same interval $\left(\rho_{q(i)}, \rho_{q(i)+1}\right)$ for some $q(i) \in\{0, \ldots, n-1\}$ or are both greater than $\rho_{n}$ (then we say that $q(i)=n$ );
$\triangleright$ either $\tau^{\lambda}(\delta, i)-L^{\lambda}(\delta, i)$ and $\left(\widetilde{\tau}^{\lambda}(\delta, i)-\widetilde{L}^{\lambda}(\delta, i)\right) / \boldsymbol{a}_{\lambda}$ both belong to the same interval $\left(\rho_{q^{\prime}(i)}, \rho_{q^{\prime}(i)+1}\right)$ for some $q^{\prime}(i) \in\{0, \ldots, n-1\}$ or are both greater than $\rho_{n}$ (then we adopt the convention that $q^{\prime}(i)=n$ ), or are both smaller than 0 (then we say that $\left.q^{\prime}(i)=-1\right)$.

We next observe that since $\delta<c_{M}$, the values of

$$
\left(Y_{t}(x), D_{t}(x)\right)_{t \in[0, T] \backslash \cup_{s \in \mathcal{T}_{M}}[s, s+\delta], x \in\left[\chi_{g}, \chi_{d}\right]}
$$

depends on $\pi_{S}$ only through its restriction to $\left[0, T_{0}\right] \times\left[\chi_{g}, \chi_{d}\right] \times[\delta, \infty)$. Furthermore, for any $t \in[0, T] \backslash \cup_{s \in \mathcal{T}_{M}}[s, s+\delta]$ and any $x \in\left[\chi_{g}, \chi_{d}\right], D_{t}(x)$ has its extremities in $\mathcal{X}_{S}^{\delta}$. Have a look at Figure 4 and use the fact that all the dotted segments with length smaller than $\delta$ cannot concern two fires. See also Remark 2.5.1 (ii).

We now distinguish several situations to prove $\left(H_{k}^{*}\right)$. We use, in all the cases below, that there are no fires in the time interval $\left(\rho_{k}, \rho_{k+1}\right)$ in the $\operatorname{LFF}(\beta)$-process in the box $\left[\chi_{g}, \chi_{d}\right]$ and no fire during $\left(\boldsymbol{a}_{\lambda} \rho_{k}, \boldsymbol{a}_{\lambda} \rho_{k+1}\right)$ for the $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process in the box $\llbracket g_{\lambda}, d_{\lambda} \rrbracket$, recall $\Omega_{A, T}^{M}(\lambda)$. Let $i \in \llbracket g_{\lambda}, d_{\lambda} \rrbracket$.

Case (a): $\eta_{a_{\lambda} \rho_{k}}^{\lambda}(i)=1$. Then by $\left(H_{k}\right), \inf _{x \in i_{\lambda}} Y_{\rho_{k}}(x)=1$. An obvious monotonicity argument shows that for all $t \in\left(\rho_{k}, \rho_{k+1}\right), \eta_{a_{\lambda} t}^{\lambda}(i)=\inf _{x \in i_{\lambda}} Y_{t}(x)=1$.

Case (b): $\eta_{a_{\lambda} \rho_{k}}^{\lambda}(i)=0$ and $S_{T_{0}}^{\lambda}(\delta, i)=\widetilde{S}_{T_{0}}^{\lambda}(\delta, i)=0$. Then $\inf _{x \in i_{\lambda}} Y_{t}(x)=1$ for all $t \in\left[\rho_{k}+\delta, \rho_{k+1}\right)$, because in $i_{\lambda}$, there is no dotted segment with length greater than $\delta$ that intersect $[0, T]$ (see Figure 4). Next, $\widetilde{S}_{T_{0}}^{\lambda}(\delta, i)=0$ means that all the delays we wait for a seed (on the site $i$ during $\left[0, a_{\lambda} T_{0}\right]$ ) are smaller than $\boldsymbol{a}_{\lambda} \delta$. Consequently,
$\eta_{\boldsymbol{a}_{\lambda} t}^{\lambda}(i)=1$ for all $t \in\left[\rho_{k}+\delta, \rho_{k+1}\right)$. Hence $\eta_{\boldsymbol{a}_{\lambda} t}^{\lambda}(i)=\inf _{x \in i_{\lambda}} Y_{t}(x)=1$ for all $t \in\left[\rho_{k}+\delta, \rho_{k+1}\right) \supset\left(\rho_{k}, \rho_{k+1}\right) \backslash \mathcal{S}$.

Case (c): $\eta_{a_{\lambda} \rho_{k}}^{\lambda}(i)=0$ and $S_{T_{0}}^{\lambda}(\delta, i)=\widetilde{S}_{T_{0}}^{\lambda}(\delta, i)=1$ and $q(i)<k$. Then $\inf _{x \in i_{\lambda}} Y_{t}(x)=1$ for all $t \in\left[\rho_{k}+\delta, \rho_{k+1}\right)$, because the only dotted segment in $i_{\lambda}$ with length greater than $\delta$ that intersects $[0, T]$ has ended before $\rho_{k}$ (because $q(i)<k$ ). Next, the only delay (between two seeds on $i$ during $\left[0, a_{\lambda} T\right]$ ) greater than $\boldsymbol{a}_{\lambda} \delta$ is ended before $\boldsymbol{a}_{\lambda} \rho_{k}$ (because $q(i)<k$ ), so that $\eta_{\boldsymbol{a}_{\lambda} t}^{\lambda}(i)=1$ for all $t \in\left[\rho_{k}+\delta, \rho_{k+1}\right)$. Hence $\eta_{a_{\lambda} t}^{\lambda}(i)=\inf _{x \in i_{\lambda}} Y_{t}(x)=1$ for all $t \in\left[\rho_{k}+\delta, \rho_{k+1}\right) \supset\left(\rho_{k}, \rho_{k+1}\right) \backslash \mathcal{S}$.

Case (d): $\quad \eta_{a_{\lambda} \rho_{k}}^{\lambda}(i)=0, S_{T_{0}}^{\lambda}(\delta, i)=\widetilde{S}_{T_{0}}^{\lambda}(\delta, i)=1$ and $q^{\prime}(i) \geq k$. Then $\inf _{x \in i_{\lambda}} Y_{t}(x)=1$ for all $t \in\left[\rho_{k}+\delta, \rho_{k+1}\right)$. Indeed, the only dotted segment in $i_{\lambda}$ with length greater than $\delta$ that intersects $[0, T]$ starts (strictly) after $\rho_{k}$ (because $\left.q^{\prime}(i) \geq k\right)$. Next, the only delay (between two seeds on $i$ during $\left[0, a_{\lambda} T\right]$ ) greater than $\boldsymbol{a}_{\lambda} \delta$ will start strictly after $\boldsymbol{a}_{\lambda} \rho_{k}$ (because $\left.q^{\prime}(i) \geq k\right)$, so that $\eta_{\boldsymbol{a}_{\lambda} t}^{\lambda}(i)=1$ for all $t \in\left[\rho_{k}+\delta, \rho_{k+1}\right)$. Hence $\eta_{a_{\lambda} t}^{\lambda}(i)=\inf _{x \in i_{\lambda}} Y_{t}(x)=1$ for all $t \in\left[\rho_{k}+\delta, \rho_{k+1}\right) \supset\left(\rho_{k}, \rho_{k+1}\right) \backslash \mathcal{S}$.
$\operatorname{Case}(\mathrm{e}): \eta_{a_{\lambda} \rho_{k}}^{\lambda}(i)=0$ and $S_{T_{0}}^{\lambda}(\delta, i)=\widetilde{S}_{T_{0}}^{\lambda}(\delta, i)=1$ and $q^{\prime}(i)<k \leq q(i)$. Then

$$
\begin{aligned}
& \eta_{a_{\lambda} t}^{\lambda}(i)=0 \text { for all } t \in\left[\rho_{k},\left(\widetilde{\tau}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda}\right) \wedge \rho_{k+1}\right) \\
& \eta_{a_{\lambda} t}^{\lambda}(i)=1 \text { for all } t \in\left[\left(\widetilde{\tau}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda}\right) \wedge \rho_{k+1}, \rho_{k+1}\right)
\end{aligned}
$$

(because no seed fall on $i$ during $\left[\widetilde{\tau}^{\lambda}(\delta, i)-\widetilde{L}^{\lambda}(\delta, i), \widetilde{\tau}^{\lambda}(\delta, i)\right) \ni \rho_{k}$ and a seed falls on $i$ at time $\left.\widetilde{\tau}^{\lambda}(\delta, i)\right)$. By $\left(H_{k}\right)$, we also know that $\inf _{x \in i_{\lambda}} Y_{\rho_{k}}(x)=0$. Calling $\left(\tau^{\lambda}(\delta, i), x_{0}, L^{\lambda}(\delta, i)\right)$ the only mark of $\pi_{S}$ that falls in $\left[0, T_{0}\right] \times i_{\lambda} \times[\delta, \infty)$, we claim that necessarily, $Y_{\rho_{k}}\left(x_{0}\right)=0$. Indeed, all the other dotted segments in $i_{\lambda}$ that intersect $[0, T]$ have a length smaller than $\delta<c_{M} \leq \rho_{k}-\rho_{k-1}$. Thus if inf $x_{x \in i_{\lambda}} Y_{\rho_{k}-}(x)=0$, necessarily, $Y_{\rho_{k}-}\left(x_{0}\right)=0$ and thus $Y_{\rho_{k}}\left(x_{0}\right)=0$. If now $\inf _{x \in i_{\lambda}} Y_{\rho_{k}-}(x)=1$, then $i_{\lambda}$ is connected at time time $\rho_{k}-$, whence the fire at time $\rho_{k}$ burns completely $i_{\lambda}$ (because $\inf _{x \in i_{\lambda}} Y_{\rho_{k}}(x)=0$ by assumption), so that in particular, $Y_{\rho_{k}}\left(x_{0}\right)=0$. Then we have to separate two situations.
$\triangleright$ If $\tau^{\lambda}(\delta, i)<\rho_{k}+\delta$, then we easily deduce that $\inf _{x \in i_{\lambda}} Y_{t}(x)=1$ for $t \in\left[\rho_{k}+\right.$ $\left.\delta, \rho_{k+1}\right)$. Recalling that $\eta_{a_{\lambda} t}^{\lambda}(i)=1$ for all $t \in\left[\left(\widetilde{\tau}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda}\right) \wedge \rho_{k+1}, \rho_{k+1}\right)$ and that $\left|\widetilde{\tau}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda}-\tau^{\lambda}(\delta, i)\right|<\alpha$, we easily conclude that $\eta_{a_{\lambda} t}^{\lambda}(i)=1$ for $t \in\left[\rho_{k}+\alpha+\delta, \rho_{k+1}\right)$. Thus $\eta_{a_{\lambda} t}^{\lambda}(i)=\inf _{x \in i_{\lambda}} Y_{t}(x)$ for $t \in\left[\rho_{k}+\delta+\alpha, \rho_{k+1}\right) \supset\left[\rho_{k}, \rho_{k+1}\right) \backslash \mathcal{S}$.
$\triangleright$ If now $\tau^{\lambda}(\delta, i) \geq \rho_{k}+\delta$, then we have, by construction, $\inf _{x \in i_{\lambda}} Y_{t}(x)=0$ for $t \in\left[\rho_{k}, \tau^{\lambda}(\delta, i) \wedge \rho_{k+1}\right)$ and $\inf _{x \in i_{\lambda}} Y_{t}(x)=1$ for $t \in\left[\tau^{\lambda}(\delta, i) \wedge \rho_{k+1}, \rho_{k+1}\right)$. Recalling the values of $\eta_{a_{\lambda} t}^{\lambda}(i)$ and that $\left|\widetilde{\tau}^{\lambda}(\delta, i) / \boldsymbol{a}_{\lambda}-\tau^{\lambda}(\delta, i)\right|<\alpha$, one easily concludes that $\eta_{a_{\lambda} t}^{\lambda}(i)=\inf _{x \in i_{\lambda}} Y_{t}(x)$ for $t \in\left[\rho_{k}, \rho_{k+1}\right) \backslash \mathcal{S}$ (because $\tau^{\lambda}(\delta, i) \in \mathcal{T}_{S}^{\delta}$ whence $\left[\tau^{\lambda}(\delta, i)-\right.$ $\left.\left.\alpha, \tau^{\lambda}(\delta, i)+\alpha\right] \subset \mathcal{S}\right)$.

We have proved $\left(H_{k}^{*}\right)$ and this implies that

$$
\forall i \in \llbracket g_{\lambda}, d_{\lambda} \rrbracket, \quad \eta_{a_{\lambda} \rho_{k+1}-}^{\lambda}(i)=\inf _{x \in i_{\lambda}} Y_{\rho_{k+1}-}(x) .
$$

It remains to prove $\left(H_{k+1}\right)$.
Consider the ignited cluster $[a, b]=D_{\rho_{k+1}-}\left(\alpha_{k+1}\right)$ in the $\operatorname{LFF}(\beta)$-process. Then the ignited cluster in the $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process at time $\boldsymbol{a}_{\lambda} \rho_{k+1}$ (due to a match falling on the site $\left\lfloor\boldsymbol{n}_{\lambda} \alpha_{k+1}\right\rfloor$ ) is nothing but $I_{k+1}^{\lambda}:=\left\{i \in \llbracket g_{\lambda}, d_{\lambda} \rrbracket: i_{\lambda} \subset D_{\rho_{k+1}-}\left(\alpha_{k+1}\right)\right\}$, at least if $\lambda$ is small enough (such that $1 / \boldsymbol{n}_{\lambda}<c_{S}$ ). Indeed, we have $\eta_{\boldsymbol{a}_{\lambda} \rho_{k+1}-}^{\lambda}(i)=$ $\inf _{x \in i_{\lambda}} Y_{\rho_{k+1}-}(x)=1$ for all $i$ such that $i_{\lambda} \subset D_{\rho_{k+1}-}\left(\alpha_{k+1}\right)$ and (on the two boundary sites) $\eta_{a_{\lambda} \rho_{k+1}-}^{\lambda}(i)=\inf _{x \in i_{\lambda}} Y_{\rho_{k+1}-}(x)=0$ for $i$ such that $i_{\lambda} \not \subset D_{\rho_{k+1}-}\left(\alpha_{k+1}\right)$ with $i_{\lambda} \cap D_{\rho_{k+1}-}\left(\alpha_{k+1}\right) \neq \varnothing$. And for $\lambda>0$ small enough (such that $\left.1 / \boldsymbol{n}_{\lambda}<c_{S}\right)$, $\left\lfloor\boldsymbol{n}_{\lambda} \alpha_{k+1}\right\rfloor \in I_{k+1}^{\lambda}$ (because $\left[a+1 / \boldsymbol{n}_{\lambda}, b-1 / \boldsymbol{n}_{\lambda}\right] \subset I_{k+1}^{\lambda}$ by the previous study, because $D_{\rho_{k+1}-}\left(\alpha_{k+1}\right)=[a, b]$ has its extremities $a, b$ in $\mathcal{X}_{S}^{\delta}$, because $\alpha_{k+1} \in \mathcal{X}_{M}$ and because the distance between $\mathcal{X}_{S}^{\delta}$ and $\mathcal{X}_{M}$ is greater than $c_{S}$, recall $\Omega_{K_{S}, c_{S}, \delta}^{S, 3}$, so that actually, $\left.\alpha_{k+1} \in\left[a+c_{S}, b-c_{S}\right]\right)$.

Then on the one hand, for all $i \in \llbracket g_{\lambda}, d_{\lambda} \rrbracket$, we have

$$
\begin{aligned}
& \inf _{x \in i_{\lambda}} Y_{\rho_{k+1}}(x)=\inf _{x \in i_{\lambda}} Y_{\rho_{k+1}-}(x) \text { if } i_{\lambda} \cap D_{\rho_{k+1}-}\left(\alpha_{k+1}\right)=\varnothing \\
& \inf _{x \in i_{\lambda}} Y_{\rho_{k+1}}(x)=0 \text { if } i_{\lambda} \cap D_{\rho_{k+1}-}\left(\alpha_{k+1}\right) \neq \varnothing
\end{aligned}
$$

The first case is obvious and the second one follows from the fact that a.s.,

$$
\pi_{S}\left(\left\{(t, x, \ell): t \geq \rho_{k+1}, x \in i_{\lambda} \cap D_{\rho_{k+1}-}\left(\alpha_{k+1}\right), t-\ell<\rho_{k+1}\right\}\right)=\infty
$$

(but this concerns marks $(t, x, \ell)$ with a very small length $\ell>0$ ).
On the other hand, for all $i \in \llbracket g_{\lambda}, d_{\lambda} \rrbracket$, we have $\eta_{\rho_{k+1}}^{\lambda}(i)=\eta_{\rho_{k+1}-}^{\lambda}(i)$ if $i \notin I_{k+1}^{\lambda}$ and $\eta_{\rho_{k+1}}^{\lambda}(i)=0$ if $i \in I_{k+1}^{\lambda}$.

As a conclusion, for all $i \in \llbracket g_{\lambda}, d_{\lambda} \rrbracket$,
$\triangleright$ if $i_{\lambda} \subset D_{\rho_{k+1}-}\left(\alpha_{k+1}\right)$, i.e. if $i \in I_{k+1}^{\lambda}$, then we have seen that $\eta_{a_{\lambda} \rho_{k+1}}^{\lambda}(i)=$ $0=\inf _{x \in i_{\lambda}} Y_{\rho_{k+1}}(x)$;
$\triangleright$ if $i_{\lambda} \cap D_{\rho_{k+1}-}\left(\alpha_{k+1}\right)=\varnothing$ (hence $\left.i \notin I_{k+1}^{\lambda}\right)$, then we have seen that $\eta_{a_{\lambda} \rho_{k+1}}^{\lambda}(i)=\eta_{a_{\lambda} \rho_{k+1}-}^{\lambda}(i)=\inf _{x \in i_{\lambda}} Y_{\rho_{k+1}-}(x)=\inf _{x \in i_{\lambda}} Y_{\rho_{k+1}}(x)$;
$\triangleright$ if $i \notin I_{k+1}^{\lambda}$ but $i_{\lambda} \cap D_{\rho_{k+1}-}\left(\alpha_{k+1}\right) \neq \varnothing$, then we have seen that $\inf _{x \in i_{\lambda}} Y_{\rho_{k+1}}(x)=0$ and $\eta_{a_{\lambda} \rho_{k+1}}^{\lambda}(i)=0$ because $\eta_{a_{\lambda} \rho_{k+1}-}^{\lambda}(i)=0$ (since then $i$ lies at the boundary of $\left.I_{k+1}^{\lambda}\right)$.
Hence $\left(H_{k+1}\right)$ holds.
Step 6. - We finally can prove (3.3.2) on $\Omega_{\lambda}$ and this will conclude the proof. First, we know from step 4 that for all $t \in[0, T]$, all $k=1, \ldots, p, D_{t}\left(x_{k}\right) \subset\left[\chi_{g}, \chi_{d}\right] \subset[-A, A]$ and that $C\left(\eta_{a_{\lambda} t}^{\lambda},\left\lfloor\boldsymbol{a}_{\lambda} x_{k}\right\rfloor\right) \subset \llbracket g_{\lambda}+1, d_{\lambda}-1 \rrbracket$ whence $D_{t}^{\lambda}\left(x_{k}\right) \subset[-A, A]$ (because $\left(g_{\lambda}+1\right) / \boldsymbol{n}_{\lambda} \geq \chi_{g} \geq-A$ and $\left.\left(d_{\lambda}-1\right) / \boldsymbol{n}_{\lambda} \leq \chi_{d} \leq A\right)$. This obviously implies that $\boldsymbol{\delta}\left(D_{t}\left(x_{k}\right), D_{t}^{\lambda}\left(x_{k}\right)\right) \leq 2 A$.

Next, step 5 implies that for all $t \in[0, T] \backslash \mathcal{S}$ (or rather for all $t \in\left[0, \rho_{n}\right) \backslash \mathcal{S}$, but the extension is straightforward), for all $i \in \llbracket g_{\lambda}, d_{\lambda} \rrbracket, \eta_{a_{\lambda} t}^{\lambda}(i)=\inf _{x \in i_{\lambda}}\left(Y_{t}(x)\right)$. This
implies that for all $t \in[0, T] \backslash \mathcal{S}$, for all $k=1, \ldots, p, \boldsymbol{\delta}\left(D_{t}^{\lambda}\left(x_{k}\right), D_{t}\left(x_{k}\right)\right) \leq 4 / \boldsymbol{n}_{\lambda}$ as desired.

Indeed, assume that $D_{t}\left(x_{k}\right)=[a, b] \subset\left[\chi_{g}, \chi_{d}\right]$ for some $t \in[0, T] \backslash \mathcal{S}$. Recall that $a, b \in \mathcal{X}_{S}^{\delta}$. We have $Y_{t}(y)=1$ for all $y \in(a, b)$ and $Y_{t}(a)=Y_{t}(b)=0$. Hence we deduce that
$\eta_{\boldsymbol{a}_{\lambda} t}^{\lambda}(i)=1$ for all $i \in\left[\left[\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor+1,\left\lfloor b \boldsymbol{n}_{\lambda}\right\rfloor-1\right]\right] \quad$ and $\quad \eta_{\boldsymbol{a}_{\lambda} t}^{\lambda}\left(\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor\right)=\eta_{\boldsymbol{a}_{\lambda} t}^{\lambda}\left(\left\lfloor b \boldsymbol{n}_{\lambda}\right\rfloor\right)=0$.
Next, we observe that for $\lambda>0$ small enough, $\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor<\left\lfloor x_{k} \boldsymbol{n}_{\lambda}\right\rfloor<\left\lfloor b \boldsymbol{n}_{\lambda}\right\rfloor$. Indeed, on $\Omega_{\lambda}$, we have, since $a, b \in \mathcal{X}_{S}^{\delta},\left|x_{k}-a\right|>c_{S}$ and $\left|b-x_{k}\right|>c_{S}$. We finally obtain

$$
C\left(\eta_{\boldsymbol{a}_{\lambda} t}^{\lambda},\left\lfloor x_{k} \boldsymbol{n}_{\lambda}\right\rfloor\right)=\left[\left[\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor+1,\left\lfloor b \boldsymbol{n}_{\lambda}\right\rfloor-1\right]\right]
$$

whence $D_{t}^{\lambda}\left(x_{k}\right)=\left[\left(\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor+1\right) / \boldsymbol{n}_{\lambda},\left(\left\lfloor b \boldsymbol{n}_{\lambda}\right\rfloor-1\right) / \boldsymbol{n}_{\lambda}\right]$. Recalling that $D_{t}(x)=[a, b]$, one easily deduces that $\boldsymbol{\delta}\left(D_{t}^{\lambda}\left(x_{k}\right), D_{t}\left(x_{k}\right)\right) \leq 4 / \boldsymbol{n}_{\lambda}$.

### 3.4. Cluster-size distribution when $\beta \in(0, \infty)$

This section is entirely devoted to the
Proof of Corollary 2.5.4. - We thus fix $\beta \in(0, \infty)$ and assume $\left(H_{M}\right)$ and $\left(H_{S}(\beta)\right)$. For each $\lambda>0$, we consider a $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. Let also $\left(Y_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ be a $\operatorname{LFF}(\beta)$-process. We know from Theorem 2.5.3 that $\left|C\left(\eta_{t}^{\lambda}, 0\right)\right| / \boldsymbol{n}_{\lambda}$ goes in law to $\left|D_{t}(0)\right|$, for any $t>0$. In step 1 below, we will check that for $t>0$, the law of $\left|D_{t}(0)\right|$ does not charge points. Thus for any $B \geq 0, t>0$, we will have

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|C\left(\eta_{t}^{\lambda}, 0\right)\right| \geq \boldsymbol{n}_{\lambda} B\right]=\operatorname{Pr}\left[\left|D_{t}(0)\right| \geq B\right]
$$

In steps 2 to 6 , we will check that there are some constants $0<c_{1}<c_{2}$ and $0<\kappa_{1}<\kappa_{2}$ such that if $t>1$, for any $B \geq 2, \operatorname{Pr}\left[\left|D_{t}(0)\right|>B\right] \in\left[c_{1} \mathrm{e}^{-\kappa_{2} B}, c_{2} \mathrm{e}^{-\kappa_{1} B}\right]$. One immediately checks that this implies

$$
\operatorname{Pr}\left[\left|D_{t}(0)\right|>B\right] \in\left[c_{1} \mathrm{e}^{-2 \kappa_{2}} \mathrm{e}^{-\kappa_{2} B},\left(c_{2} \vee \mathrm{e}^{2 \kappa_{1}}\right) \mathrm{e}^{-\kappa_{1} B}\right]
$$

for all $t>1, B>0$ and this will conclude the proof.
Step 1. - The goal of this step is to check that for any $t>0$ fixed, the law of $\left|D_{t}(0)\right|$ does not charge points.

Consider the first mark $\left(T_{d}, \chi_{d}, L_{d}\right)$ of $\pi_{S}$ on the right of $0\left(\chi_{d}>0\right)$ such that $[0, t] \subset\left[T_{d}-L_{d}, T_{d}\right]$. Consider a similar mark $\left(T_{g}, \chi_{g}, L_{g}\right)$ of $\pi_{S}$ with $\chi_{g}<0$.

Then $Y_{s}\left(\chi_{g}\right)=Y_{s}\left(\chi_{d}\right)=0$ for all $s \in[0, t]$, so that fires falling outside [ $\left.\chi_{g}, \chi_{d}\right]$ cannot affect 0 during $[0, t]$.

Next, denote by $\left(T_{M}, X_{M}\right)$ the instant/position of the last match falling before $t$ in $\left[\chi_{g}, \chi_{d}\right]$. Then a.s., $t-T_{M}>0$, and $D_{t}(0)$ is of the form $[a, b]$, for some marks $\left(T_{a}, a, L_{a}\right)$ and $\left(T_{b}, b, L_{b}\right)$ of $\pi_{S}$ satisfying $\chi_{g} \leq a<0<b<\chi_{d}, T_{a}-L_{a}<T_{M}$, $T_{b}-L_{b}<T_{M}, T_{a}>t$ and $T_{b}>t$. There are a.s. a finite number of such marks
(because a.s., $\left.\int_{t}^{\infty} \mathrm{d} s \int_{s-T_{M}}^{\infty} \beta(\beta+1) \ell^{-\beta-2} \mathrm{~d} \ell=\left(t-t_{M}\right)^{-\beta}<\infty\right)$, and their (spatial) positions clearly have densities, whence the result.

Step 2. - For $t>1, a \in \mathbb{R}$, we consider the event $\Omega_{t, a}$ defined as follows, see Figure 6 next page:
(i) $\pi_{M}$ has exactly one mark $\left(T_{M}, X_{M}\right)$ in $[t-1, t] \times[a, a+1]$ and there holds $\left(T_{M}, X_{M}\right) \in\left[t-\frac{2}{3}, t-\frac{1}{2}\right] \times\left[a+\frac{1}{4}, a+\frac{3}{4}\right] ;$
(ii) $\pi_{S}$ has one mark $\left(T_{g}, X_{g}, L_{g}\right)$ such that $T_{g}-L_{g}<t-1<t<T_{g}$ and $X_{g} \in\left[a, a+\frac{1}{4}\right]$ and one mark $\left(T_{d}, X_{d}, L_{d}\right)$ such that $T_{d}-L_{d}<t-1<t<T_{d}$ and $X_{d} \in\left[a+\frac{3}{4}, a+1\right]$ (recalling Figure 4, there are dotted vertical segments in $\left[a, a+\frac{1}{4}\right]$ and in $\left[a+\frac{3}{4}, a+1\right]$ that run across $\left.[t-1, t]\right)$;
(iii) all the other marks $(T, X, L)$ of $\pi_{S}$ with $X \in[a, a+1]$ and $[T-L, T] \cap[t-1, t]$ not empty satisfy $L<\frac{1}{4}$ (recalling Figure 4, all the other vertical dotted segments in $[a, a+1]$ that intersect $[t-1, t]$ have a length smaller than $\frac{1}{4}$ ).
Step 3. - In this step, we prove that on $\Omega_{t, a}$, we have either $Y_{s}\left(X_{g}\right)=0$ for all $s \in\left[t-\frac{1}{2}, t\right]$ or $Y_{s}\left(X_{d}\right)=0$ for all $s \in\left[t-\frac{1}{2}, t\right]$. We distinguish two situations.
$\triangleright$ First assume that $\left[X_{g}, X_{d}\right]$ is connected at time $T_{M}$ (that is $Y_{T_{M}-}(x)=1$ for all $\left.x \in\left[X_{g}, X_{d}\right]\right)$. Since $X_{M} \in\left[X_{g}, X_{d}\right]$, the fire destroys the cluster and thus we deduce that $Y_{s}\left(X_{g}\right)=0$ for all $s \in\left[T_{M}, T_{g}\right) \supset\left[t-\frac{1}{2}, t\right]$ and that $Y_{s}\left(X_{d}\right)=0$ for all $s \in\left[T_{M}, T_{d}\right) \supset\left[t-\frac{1}{2}, t\right]$.
$\triangleright$ Next assume that $\left[X_{g}, X_{d}\right] \subset[a, a+1]$ is not connected at time $T_{M}-($ that is, there is some $x_{0} \in\left[X_{g}, X_{d}\right]$ such that $\left.Y_{T_{M}-}\left(x_{0}\right)=0\right)$. Then we claim that either $Y_{T_{M}-}\left(X_{g}\right)=0\left(\right.$ then $Y_{s}\left(X_{g}\right)=0$ for all $\left.s \in\left[T_{M}, T_{g}\right) \supset\left[t-\frac{1}{2}, t\right]\right)$ or $Y_{T_{M}-}\left(X_{d}\right)=0\left(\right.$ then $Y_{s}\left(X_{d}\right)=0$ for all $\left.s \in\left[T_{M}, T_{d}\right) \supset\left[t-\frac{1}{2}, t\right]\right)$. Indeed, recall that all the dotted segments that intersect $[t-1, t]$ in $\left(X_{g}, X_{d}\right)$ have a length smaller than $\frac{1}{4}$. Thus if $\left[X_{g}, X_{d}\right]$ is disconnected at time $T_{M}$ - due to a fire that started before $t-1$, it can be only with $x_{0}=X_{g}$ or $x_{0}=X_{d}$, whence the conclusion. But if now $\left[X_{g}, X_{d}\right]$ is disconnected at time $T_{M}$ - due to a fire that started at some time $\tau \in\left[t-1, T_{M}\right)$ at some place $\chi \notin[a, a+1]$ (since there are no fires in $[a, a+1]$ during $\left[t-1, T_{M}\right)$ ), this necessarily also concerns one of the extremities $X_{g}$ or $X_{d}$ of $\left[X_{g}, X_{d}\right]$. Thus in any case, we obtain either $Y_{T_{M}-}\left(X_{g}\right)=0$ or $Y_{T_{M}-}\left(X_{d}\right)=0$ as desired.
Step 4. - Let us prove that $p:=\operatorname{Pr}\left[\Omega_{t, a}\right]>0$. This value will obviously does not depend on $a \in \mathbb{R}, t \geq 1$, by homogeneity in $(s, x)$ of the Poisson measures $\pi_{M}(\mathrm{~d} s, \mathrm{~d} x)$ and $\pi_{S}(\mathrm{~d} s, \mathrm{~d} x, \mathrm{~d} \ell)$. Define the zones

$$
\begin{aligned}
& A_{M}=\left(t-\frac{2}{3}, t-\frac{1}{2}\right) \times\left(a+\frac{1}{4}, a+\frac{3}{4}\right) \\
& B_{M}=((t-1, t) \times(a, a+1)) \backslash A_{M} \\
& A_{S}=\left\{(s, x, \ell), x \in\left(a, a+\frac{1}{4}\right), s>t>t-1>s-\ell\right\},
\end{aligned}
$$

Figure 6. The event $\Omega_{t, A}$.

$$
\begin{aligned}
B_{S} & =\left\{(s, x, \ell), x \in\left(a+\frac{3}{4}, a+1\right), s>t>t-1>s-\ell\right\} \\
C_{S} & =\left\{(s, x, \ell), x \in\left(a+\frac{1}{4}, a+\frac{3}{4}\right), s>t>t-1>s-\ell\right\} \\
D_{S} & =\left\{(s, x, \ell), x \in(a, a+1),[s-\ell, s] \cap[t-1, t] \neq \varnothing, \ell>\frac{1}{4}\right\} \backslash\left(A_{S} \cup B_{S} \cup C_{S}\right) .
\end{aligned}
$$

The zones $A_{M}$ and $B_{M}$ are disjoint and for $\zeta_{M}(\mathrm{~d} s, \mathrm{~d} x)=\mathrm{d} s \mathrm{~d} x, \zeta_{M}\left(A_{M}\right)=\frac{1}{12}$ and $\zeta_{M}\left(B_{M}\right)=\frac{11}{12}$. The zones $A_{S}, B_{S}, C_{S}, D_{S}$ are also disjoint and simple computations show that, for $\zeta_{S}(\mathrm{~d} s, \mathrm{~d} x, \mathrm{~d} \ell)=\beta(\beta+1) \ell^{-\beta-2} \mathrm{~d} s \mathrm{~d} x \mathrm{~d} \ell, \zeta_{S}\left(A_{S}\right)=\zeta_{S}\left(B_{S}\right)=\frac{1}{4}$, $\zeta_{S}\left(C_{S}\right)=\frac{1}{2}$ and $\zeta_{S}\left(D_{S}\right)=4^{\beta}(5 \beta+1)-1$. Consequently, recalling that $\pi_{M}$ and $\pi_{S}$ are independent Poisson measures with intensity measures $\zeta_{M}$ and $\zeta_{S}$,

$$
\begin{aligned}
\operatorname{Pr}\left[\Omega_{t, a, \delta}\right]=\operatorname{Pr}\left(\pi_{M}\left(A_{M}\right)=1, \pi_{M}\left(B_{M}\right)=0, \pi_{S}\left(A_{S}\right)=\right. & \pi_{S}\left(B_{S}\right)=1 \\
& \left.\pi_{S}\left(C_{S}\right)=\pi_{S}\left(D_{S}\right)=0\right)
\end{aligned}
$$

$$
\begin{aligned}
& =\zeta\left(A_{M}\right) \mathrm{e}^{-\zeta_{M}\left(A_{M}\right)} \mathrm{e}^{-\zeta_{M}\left(B_{M}\right)} \zeta_{S}\left(A_{S}\right) \mathrm{e}^{-\zeta_{S}\left(A_{S}\right)} \\
& \quad \zeta_{S}\left(B_{S}\right) \mathrm{e}^{-\zeta_{S}\left(B_{S}\right)} \mathrm{e}^{-\zeta_{S}\left(C_{S}\right)} \mathrm{e}^{-\zeta_{S}\left(D_{S}\right)} \\
& =\frac{1}{12} \mathrm{e}^{-\frac{1}{1} 2} \mathrm{e}^{-\frac{11}{12}}\left(\frac{1}{4}\right)^{2} \mathrm{e}^{-\frac{1}{2}} \mathrm{e}^{-4^{\beta}(5 \beta+1)+1}=: p>0
\end{aligned}
$$

Step 5. - We clearly have, for any $t \geq 1$, any $B \geq 2$,

$$
\left\{\left|D_{t}(0)\right| \geq B\right\} \subset\left\{\forall x \in\left[0, \frac{1}{2} B\right], Y_{t}(x)=1\right\} \cup\left\{\forall x \in\left[-\frac{1}{2} B, 0\right], Y_{t}(x)=1\right\}
$$

whence $\operatorname{Pr}\left[\left|D_{t}(0)\right| \geq B\right] \leq 2 \operatorname{Pr}\left[\forall x \in\left[0, \frac{1}{2} B\right], Y_{t}(x)=1\right]$ by symmetry. Furthermore, step 3 implies that

$$
\left\{\forall x \in\left[0, \frac{1}{2} B\right], Y_{t}(x)=1\right\} \subset \Omega_{t, 0}^{c} \cap \Omega_{t, 1}^{c} \cap \cdots \cap \Omega_{t,\left\lfloor\frac{1}{2} B-1\right\rfloor}^{c}
$$

Using then step 4 (and some obvious independence arguments), we get

$$
\operatorname{Pr}\left[\left|D_{t}(0)\right| \geq B\right] \leq 2(1-p)^{)^{\left.\frac{1}{2} B-1\right\rfloor+1}} \leq 2(1-p)^{\frac{1}{2} B-1}
$$

Consequently, for all $t \geq 1$, all $B \geq 2, \operatorname{Pr}\left[\left|D_{t}(0)\right| \geq B\right] \leq c_{2} \mathrm{e}^{-\kappa_{1} B}$, with $c_{2}=2 /(1-p)$ and $\kappa_{1}=-\frac{1}{2}[\log (1-p)]$.

Step 6. - Next, we consider the event $\widetilde{\Omega}_{t, B}$ on which:
(i) $\pi_{M}\left(\left[t-\frac{1}{2}, t\right] \times[0, B]\right)=0$;
(ii) all the marks $(T, X, L)$ of $\pi_{S}$ with $X \in[0, B]$ satisfy either $T<t$ or $T-L>t-\frac{1}{2}$ ) (this means that there is no dotted vertical segment running across $\left[t-\frac{1}{2}, t\right]$ in $\left.[0, B]\right)$.
An easy computation as in step 4 implies that

$$
\begin{aligned}
\operatorname{Pr}\left[\widetilde{\Omega}_{t, B}\right] & =\exp \left(-\int_{t-\frac{1}{2}}^{t} \int_{0}^{B} \mathrm{~d} s \mathrm{~d} x-\int_{t}^{\infty} \mathrm{d} s \int_{0}^{B} \mathrm{~d} x \int_{s-t+\frac{1}{2}}^{\infty} \mathrm{d} \ell \beta(\beta+1) \ell^{-\beta-2}\right) \\
& =\exp \left(-\frac{1}{2} B-2^{\beta} B\right)
\end{aligned}
$$

We claim that on $\Omega_{t,-1} \cap \widetilde{\Omega}_{t, B} \cap \Omega_{t, B}$, we have $[0, B] \subset D_{t}(0)$, whence $\left|D_{t}(0)\right| \geq B$. Indeed, we know from step 3 that there is $\chi_{0} \in[-1,0]$ and $\chi_{1} \in[B, B+1]$ such that $Y_{s}\left(\chi_{0}\right)=Y_{s}\left(\chi_{1}\right)=0$ for all $s \in\left[t-\frac{1}{2}, 1\right]$. Thus the fires starting outside $\left[\chi_{0}, \chi_{1}\right]$ do not affect the zone $\left[\chi_{0}, \chi_{1}\right]$ during $\left[t-\frac{1}{2}, t\right]$. Furthermore, there are no fires starting in $\left[\chi_{0}, \chi_{1}\right]$ during $\left[t-\frac{1}{2}, t\right]$. At last, since all the dotted segments in $[0, B]$ intersecting $\{t\}$ have started after $t-\frac{1}{2}$. We easily conclude that $Y_{t}(x)=1$ for all $x \in[0, B]$.

Using finally some obvious independence arguments, we get

$$
\operatorname{Pr}\left[\left|D_{t}(0)\right| \geq B\right] \geq \operatorname{Pr}\left[\Omega_{t,-1} \cap \widetilde{\Omega}_{t, B} \cap \Omega_{t, B}\right] \geq p^{2} \exp \left(-\frac{1}{2} B-2^{\beta} B\right)=c_{1} \mathrm{e}^{-\kappa_{2} B}
$$

with $c_{1}=p^{2}$ and $\kappa_{2}=\frac{1}{2}+2^{\beta}$.

### 3.5. Convergence proof when $\beta=0$

This case is simpler than the case $\beta \in(0, \infty)$, but a little work is however needed. We also divide the section into three parts: preliminaries, coupling of seeds and convergence proof. In the whole section, we assume $\left(H_{M}\right)$ and $\left(H_{S}(0)\right)$. We recall that $\boldsymbol{a}_{\lambda}$ and $\boldsymbol{n}_{\lambda}$ are defined in (2.2.1) and (2.2.2). For $A>0$ and $i \in \mathbb{Z}$, we set

$$
A_{\lambda}=\left\lfloor A \boldsymbol{n}_{\lambda}\right\rfloor, \quad I_{A}^{\lambda}=\llbracket-A_{\lambda}, A_{\lambda} \rrbracket, \quad i_{\lambda}=\left[i / \boldsymbol{n}_{\lambda},(i+1) / \boldsymbol{n}_{\lambda}\right) .
$$

3.5.1. Preliminaries. - The proof will use the following estimate.

Lemma 3.5.1. - For any $\ell \in(0, \infty)$ fixed, we have $\lim _{\lambda \rightarrow 0} \lambda^{-1} \mu_{S}\left(\left(a_{\lambda} \ell, \infty\right)\right)=0$.
Proof. - Using the monotonicity of $\mu_{S}((x, \infty))$ and since $\mu_{S}((x, \infty)) \mathrm{d} x=m_{S} \nu_{S}(\mathrm{~d} x)$,

$$
\begin{aligned}
\frac{\mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)}{\lambda} & \leq \frac{2}{\lambda \boldsymbol{a}_{\lambda} \ell} \int_{\boldsymbol{a}_{\lambda} \ell / 2}^{\boldsymbol{a}_{\lambda} \ell} \mu_{S}((x, \infty)) \mathrm{d} x \\
& =\frac{2 m_{S}}{\lambda \boldsymbol{a}_{\lambda} \ell}\left[\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell / 2, \infty\right)\right)-\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)\right] \\
& =\frac{2 m_{S}}{\ell}\left[\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell / 2, \infty\right)\right) / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)-\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right) / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)\right]
\end{aligned}
$$

For the last equality, we used that by definition, $\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)=\lambda \boldsymbol{a}_{\lambda}$. Using $\left(H_{S}(0)\right)$, we easily conclude.

The following statement contains some crucial facts about accelerated $\operatorname{SR}\left(\mu_{S}\right)$ processes under $\left(H_{S}(0)\right)$.

Lemma 3.5.2. - Let $\left(T_{n}\right)_{n \geq 1}$ be a $\operatorname{SR}\left(\mu_{S}\right)$-process (see subsection 2.1.1). For $\lambda>0, t \geq 0$ and $\ell>0$, we set

$$
R_{t}^{\lambda}(\ell)=\#\left\{n \geq 1: T_{n} \in\left[0, \boldsymbol{a}_{\lambda} t\right], T_{n+1}-T_{n} \geq \boldsymbol{a}_{\lambda} \ell\right\}
$$

which represents the number of delays with length greater than $\boldsymbol{a}_{\lambda} \ell$ that start in $\left[0, \boldsymbol{a}_{\lambda} t\right]$.
(i) For any $T>0, \operatorname{Pr}\left[T_{1} \geq \boldsymbol{a}_{\lambda} T\right]=\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} T, \infty\right)\right) \sim \lambda \boldsymbol{a}_{\lambda}$ as $\lambda \rightarrow 0$.
(ii) For any $T>0$, any $\ell>0$, as $\lambda \rightarrow 0$

$$
\mathbb{E}\left[R_{T}^{\lambda}(\ell)\right]=\boldsymbol{a}_{\lambda} T \mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right) / m_{S}=o\left(\lambda \boldsymbol{a}_{\lambda}\right)
$$

Proof. - Point (i) is immediate: $\nu_{S}$ is the law of $T_{1}$ and since $\lambda \boldsymbol{a}_{\lambda}=\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)$ by definition, one has $\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} T, \infty\right)\right)=\lambda \boldsymbol{a}_{\lambda} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} T, \infty\right)\right) / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)$. One concludes using $\left(H_{S}(0)\right)$. Point (ii) is slightly more delicate. First, we complete the $\operatorname{SR}\left(\mu_{S}\right)$-process $\left(T_{n}\right)_{n \geq 1}$ in $\left(T_{n}\right)_{n \in \mathbb{Z}}$, see subsection 2.1.1. Then we observe that since $T_{0}<0<T_{1}$,

$$
R_{T}^{\lambda}(\ell)=\#\left\{n \in \mathbb{Z}: T_{n} \in\left[0, a_{\lambda} T\right], T_{n+1}-T_{n} \geq \boldsymbol{a}_{\lambda} \ell\right\}
$$

Next, we set

$$
\tau_{n}=\boldsymbol{a}_{\lambda} T-T_{-n}
$$

and we introduce $n_{0}$ such that $\tau_{n_{0}}<0<\tau_{n_{0}+1}$. We put

$$
\widetilde{T}_{n}=\tau_{n_{0}+n}
$$

Then $\left(\widetilde{T}_{n}\right)_{n \in \mathbb{Z}}$ is also a $\operatorname{SR}\left(\mu_{S}\right)$-process (see subsection 2.1.1). We have

$$
\begin{aligned}
R_{T}^{\lambda}(\ell) & =\#\left\{n \in \mathbb{Z}: \boldsymbol{a}_{\lambda} T-T_{n} \in\left[0, \boldsymbol{a}_{\lambda} T\right],\left(\boldsymbol{a}_{\lambda} T-T_{n}\right)-\left(\boldsymbol{a}_{\lambda} T-T_{n+1}\right) \geq \boldsymbol{a}_{\lambda} \ell\right\} \\
& =\#\left\{n \in \mathbb{Z}: \widetilde{T}_{-n-n_{0}} \in\left[0, \boldsymbol{a}_{\lambda} T\right], \widetilde{T}_{-n-n_{0}}-\widetilde{T}_{-n-1-n_{0}} \geq \boldsymbol{a}_{\lambda} \ell\right\} \\
& =\#\left\{n \in \mathbb{Z}: \widetilde{T}_{n} \in\left[0, \boldsymbol{a}_{\lambda} T\right], \widetilde{T}_{n}-\widetilde{T}_{n-1} \geq \boldsymbol{a}_{\lambda} T\right\} \\
& =\#\left\{n \geq 1: \widetilde{T}_{n} \in\left[0, \boldsymbol{a}_{\lambda} T\right], \widetilde{T}_{n}-\widetilde{T}_{n-1} \geq \boldsymbol{a}_{\lambda} \ell\right\}=: \widetilde{S}_{T}^{\lambda}(\ell) .
\end{aligned}
$$

We used that $\widetilde{T}_{0}<0<\widetilde{T}_{1}$ by construction. But $\widetilde{S}_{T}^{\lambda}(\ell)$ is the number of delays with length greater than $\boldsymbol{a}_{\lambda} \ell$ that end in $\left[0, \boldsymbol{a}_{\lambda} T\right]$, for the $\operatorname{SR}\left(\mu_{S}\right)$-process $\left(\widetilde{T}_{n}\right)_{n \in \mathbb{Z}}$. Thus exactly as in the proof of Lemma 3.3.2 (steps 1 and 2), we get

$$
\mathbb{E}\left[\widetilde{S}_{T}^{\lambda}(\ell)\right]=m_{S}^{-1} \boldsymbol{a}_{\lambda} T \mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right),
$$

so that

$$
\mathbb{E}\left[R_{T}^{\lambda}(\ell)\right]=m_{S}^{-1} \boldsymbol{a}_{\lambda} T \mu_{S}\left(\left(\boldsymbol{a}_{\lambda} \ell, \infty\right)\right)
$$

Finally, Lemma 3.5.1 implies that $\mathbb{E}\left[R_{T}^{\lambda}(\ell)\right]=o\left(\lambda \boldsymbol{a}_{\lambda}\right)$.
3.5.2. Coupling of seeds. - We aim here to couple the Poisson measure $\pi_{S}(\mathrm{~d} x)$ used to build the $\operatorname{LFF}(0)$-process with a family of $\operatorname{SR}\left(\mu_{S}\right)$-processes, in such a way that roughly:
$\triangleright$ if $\pi_{S}\left(i_{\lambda}\right)>0$, then the first seed never falls on $i$;
$\triangleright$ if $\pi_{S}\left(i_{\lambda}\right)=0$, then seeds fall almost continuously on $i$.
The precise statement is as follows.

Proposition 3.5.3. - Let $A>0, T>0, \delta>0$ be fixed. For any $\lambda \in(0,1]$, it is possible to find a coupling between a Poisson measure $\pi_{S}$ on $\mathbb{R}$ with intensity measure $\mathrm{d} x$ and a family $\left(N_{t}^{S}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ of $\operatorname{SR}\left(\mu_{S}\right)$-processes in such a way that for

$$
\begin{aligned}
& \Omega_{A, T, \delta}^{S}(\lambda)=\bigcap_{i \in I_{A}^{\lambda}}\left(\left\{\pi_{S}\left(i_{\lambda}\right)=0, \inf _{t \in[0, T-\delta]}\left[N_{a_{\lambda}(t+\delta)}^{S}(i)-N_{a_{\lambda} t}^{S}(i)\right]>0\right\}\right. \\
&\left.\cup\left\{\pi_{S}\left(i_{\lambda}\right)=1, N_{a_{\lambda} T}^{S}(i)=0\right\}\right),
\end{aligned}
$$

one has $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\Omega_{A, T, \delta}^{S}(\lambda)\right]=1$.
Proof. - We split the proof in several steps. As usual, it suffices to build $\pi_{S}$ on $B_{\lambda}=\bigcup_{i \in I_{A}^{\lambda}} i_{\lambda} \simeq[-A, A]$ and to build $N_{t}^{S}(i)$ for $t \in\left[0, a_{\lambda} T\right]$ and $i \in I_{A}^{\lambda}$.

Step 1. - Denote by $\left(N_{t}^{S}\right)_{t \geq 0}$ a $\operatorname{SR}\left(\mu_{S}\right)$-process and by $\left(T_{n}\right)_{n \geq 1}$ its jump instants. Recall the notation of Lemma 3.5.2. Then we observe that

$$
\begin{aligned}
& \left\{N_{a_{\lambda} T}^{S}=0\right\}=\left\{T_{1}>\boldsymbol{a}_{\lambda} T\right\} \\
& \left\{\inf _{t \in[0, T-\delta]}\left[N_{a_{\lambda}(t+\delta)}^{S}-N_{a_{\lambda} t}^{S}\right]>0\right\}=\left\{T_{1}<\boldsymbol{a}_{\lambda} \delta, R_{T}^{\lambda}(\delta)=0\right\}
\end{aligned}
$$

These two events are furthermore disjoint. By Lemma 3.5.2, we deduce that for some functions $\varepsilon_{T}(\lambda)$ and $\varepsilon_{T, \delta}(\lambda)$ tending to 0 when $\lambda \rightarrow 0$

$$
\begin{aligned}
\operatorname{Pr}\left[\inf _{t \in[0, T-\delta]}\left[N_{\boldsymbol{a}_{\lambda}(t+\delta)}^{S}-N_{\boldsymbol{a}_{\lambda} t}^{S}\right]>0\right] & \geq 1-\operatorname{Pr}\left[T_{1}>\boldsymbol{a}_{\lambda} \delta\right]-\mathbb{E}\left[R_{T}^{\lambda}(\delta)\right] \\
& \geq 1-\lambda \boldsymbol{a}_{\lambda}\left(1+\varepsilon_{T, \delta}(\lambda)\right)
\end{aligned}
$$

and $p_{T}(\lambda):=\operatorname{Pr}\left[N_{\boldsymbol{a}_{\lambda} T}^{S}=0\right]=\operatorname{Pr}\left[T_{1}>\boldsymbol{a}_{\lambda} T\right]=\lambda \boldsymbol{a}_{\lambda}\left(1+\varepsilon_{T}(\lambda)\right)$.
Step 2. - Next, we prove that it is possible to couple a family $\left(Z_{i}^{\lambda}\right)_{i \in I_{A}^{\lambda}}$ of i.i.d. Poisson-distributed random variables with parameter $\left|i_{\lambda}\right|=1 / \boldsymbol{n}_{\lambda}$ and a family of $\left(\widetilde{Z}_{i}^{\lambda}\right)_{i \in I_{A}^{\lambda}}$ of i.i.d. Bernoulli random variables with parameter $p_{T}(\lambda)$ (see step 1 ) in such a way that for

$$
\widetilde{\Omega}_{T, A}(\lambda)=\left\{\forall i \in I_{A}^{\lambda}, Z_{i}^{\lambda}=\widetilde{Z}_{i}^{\lambda} \in\{0,1\}\right\},
$$

there holds $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\widetilde{\Omega}_{T, A}(\lambda)\right]=1$. As usual, this follows from Lemma 5.1.3 (ii) and relies on the straightforward computations (here the function $\varepsilon_{T}$ changes from line to line)

$$
\operatorname{Pr}\left[Z_{i}^{\lambda}=0\right] \wedge \operatorname{Pr}\left[\widetilde{Z}_{i}^{\lambda}=0\right]=\left(\mathrm{e}^{-1 / n_{\lambda}}\right) \wedge\left(1-p_{T}(\lambda)\right) \geq 1-\lambda \boldsymbol{a}_{\lambda}\left(1+\varepsilon_{T}(\lambda)\right)
$$

recall that $\boldsymbol{n}_{\lambda} \sim 1 /\left(\lambda \boldsymbol{a}_{\lambda}\right)$, and

$$
\operatorname{Pr}\left[Z_{i}^{\lambda}=1\right] \wedge \operatorname{Pr}\left[\widetilde{Z}_{i}^{\lambda}=1\right]=\left(\mathrm{e}^{-1 / \boldsymbol{n}_{\lambda}} / \boldsymbol{n}_{\lambda}\right) \wedge p_{T}(\lambda) \geq \lambda \boldsymbol{a}_{\lambda}\left(1-\varepsilon_{T}(\lambda)\right)
$$

from which

$$
\operatorname{Pr}\left[\widetilde{\Omega}_{T, A}(\lambda)\right] \geq\left[1-\lambda \boldsymbol{a}_{\lambda}\left(1+\varepsilon_{T}(\lambda)\right)+\lambda \boldsymbol{a}_{\lambda}\left(1-\varepsilon_{T}(\lambda)\right)\right]^{\left|I_{A}^{\lambda}\right|} \geq\left[1-\lambda \boldsymbol{a}_{\lambda} \varepsilon_{T}(\lambda)\right]^{\left|I_{A}^{\lambda}\right|}
$$

This last quantity tends to 1 as $\lambda \rightarrow 0$, because $\left|I_{A}^{\lambda}\right| \sim 2 A /\left(\lambda \boldsymbol{a}_{\lambda}\right)$.
Step 3. - We finally build the complete coupling.
(a) Consider $\left(Z_{i}^{\lambda}, \widetilde{Z}_{i}^{\lambda}\right)_{i \in I_{A}^{\lambda}}$ as in step 2.
(b) For each $i \in I_{A}^{\lambda}$ such that $Z_{i}^{\lambda}>0$, pick some i.i.d. random variables $\left(X_{1}^{i, \lambda}, \ldots, X_{Z_{i}^{\lambda}}^{i, \lambda}\right)$ uniformly distributed in $i_{\lambda}$. Then $\pi_{S}=\sum_{i \in I_{A}^{\lambda}} \sum_{k=1}^{Z_{i}^{\lambda}} \delta_{X_{k}^{i, \lambda}}$ is a Poisson measure with intensity measure $\mathrm{d} x$ on $B_{\lambda}=\bigcup_{i \in I_{A}^{\lambda}} i_{\lambda}$.
(c) For each $i \in I_{A}^{\lambda}$ such that $\widetilde{Z}_{i}^{\lambda}=1$, set $N_{a_{\lambda} T}^{S}(i)=0$. For each $i \in I_{A}^{\lambda}$ such that $\widetilde{Z}_{i}^{\lambda}=0$, pick $\left(N_{t}^{S}(i)\right)_{t \in\left[0, a_{\lambda} T\right]}$ conditionally on $N_{a_{\lambda} T}^{S}(i) \neq 0$. This defines a family of i.i.d. $\mathrm{SR}\left(\mu_{S}\right)$ processes on $\left[0, \boldsymbol{a}_{\lambda} T\right]$ (because $\operatorname{Pr}\left[\widetilde{Z}_{i}^{\lambda}=1\right]=p_{T}(\lambda)=$ $\operatorname{Pr}\left[N_{\boldsymbol{a}_{\lambda} T}^{S}(i)=0\right]$ ).

Step 4. - With this coupling, we have $\widetilde{\Omega}_{T, A}(\lambda) \cap \bar{\Omega}_{A, T, \delta}^{S}(\lambda) \subset \Omega_{A, T, \delta}^{S}(\lambda)$, where

$$
\bar{\Omega}_{A, T, \delta}^{S}(\lambda)=\bigcap_{i \in I_{A}^{\lambda}}\left(\inf _{t \in[0, T-\delta]}\left[N_{\boldsymbol{a}_{\lambda}(t+\delta)}^{S}(i)-N_{\boldsymbol{a}_{\lambda} t}^{S}(i)\right]>0 \text { or } N_{\boldsymbol{a}_{\lambda} T}^{S}(i)=0\right)
$$

It thus only remains to check that $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\bar{\Omega}_{A, T, \delta}^{S}(\lambda)\right]=1$. But using step 1 and recalling that $\left|I_{A}^{\lambda}\right| \sim 2 A /\left(\lambda \boldsymbol{a}_{\lambda}\right)$, we get

$$
\operatorname{Pr}\left[\bar{\Omega}_{A, T, \delta}^{S}(\lambda)\right] \geq\left[1-\lambda \boldsymbol{a}_{\lambda}\left(1+\varepsilon_{T, \delta}(\lambda)\right)+\lambda \boldsymbol{a}_{\lambda}\left(1+\varepsilon_{T}(\lambda)\right)\right]^{\left|I_{A}^{\lambda}\right|}
$$

which tends to 1 as $\lambda \rightarrow 0$, as usual, since $\left|I_{A}^{\lambda}\right| \sim 2 A /\left(\lambda \boldsymbol{a}_{\lambda}\right)$.
3.5.3. Convergence. - We now prove the convergence result in the case $\beta=0$.

Proof of Theorem 2.6.2. - We fix $T>0, x_{1}<\cdots<x_{p}$ and $t_{1}, \ldots, t_{p} \in(0, T]$. We introduce $B>0$ such that $-B<x_{1}<x_{p}<B$. We fix $\varepsilon>0$ and $a>0$. Our aim is to check that for $\lambda>0$ small enough, there exists a coupling between a $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$ process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ and a LFF $(0)$-process $\left(Y_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ such that, recalling (2.2.3) and Proposition 2.6.1, there holds

$$
\begin{equation*}
\operatorname{Pr}\left[\sum_{k=1}^{p} \boldsymbol{\delta}_{T}\left(D^{\lambda}\left(x_{k}\right), D\left(x_{k}\right)\right)+\sum_{k=1}^{p} \boldsymbol{\delta}\left(D_{t_{k}}^{\lambda}\left(x_{k}\right), D_{t_{k}}\left(x_{k}\right)\right) \geq a\right] \leq \varepsilon \tag{3.5.1}
\end{equation*}
$$

This will conclude the proof.
Step 1. - Consider two independent Poisson measures $\pi_{S}(\mathrm{~d} x)$ and $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)$ with intensity measures $\mathrm{d} x$ and $\mathrm{d} t \mathrm{~d} x$. First, we consider $A>B$ large enough, in such a way that for

$$
\Omega_{A}^{S, 1}=\left\{\pi_{S}([-A,-B])>0, \pi_{S}([B, A])>0\right\}
$$

there holds $\operatorname{Pr}\left(\Omega_{A}^{S, 1}\right) \geq 1-\frac{1}{4} \varepsilon$. This fixes the value of $A$. Next we call

$$
\begin{aligned}
\mathcal{X}_{S} & =\left\{x \in[-A, A], \pi_{S}(\{x\})>0\right\} \\
\mathcal{T}_{M} & =\left\{t \in[0, T]: \pi_{M}(\{t\} \times[-A, A])>0\right\} \cup\{0\} \\
\mathcal{X}_{M} & =\left\{x \in[-A, A], \pi_{M}([0, T] \times\{x\})>0\right\}
\end{aligned}
$$

Classical results about Poisson measures allow us to choose $K>0$ (large) and $c>0$ (small) in such a way that for

$$
\Omega_{K, c}=\left\{\left|\mathcal{T}_{M}\right|+\left|\mathcal{X}_{S}\right| \leq K, \min _{\substack{t \in \mathcal{T}_{M} \\ k=1, \ldots, p}}\left|t-t_{k}\right|>c, \min _{\substack{x, y \in \mathcal{X}_{S} \cup \mathcal{X}_{M} \\ x \neq y}}|x-y|>c, \min _{\substack{x \in \mathcal{X}_{S} \cup \mathcal{X}_{M} \\ k=1, \ldots, p}}\left|x-x_{k}\right|>c\right\},
$$

there holds $\operatorname{Pr}\left[\Omega_{K, c}\right] \geq 1-\frac{1}{4} \varepsilon$.

Step 2. - Next, we know from Proposition 3.2.1 that for all $\lambda>0$ small enough, it is possible to couple a family of i.i.d. $\operatorname{SR}\left(\mu_{M}^{\lambda}\right)$-processes $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}\}}$ with $\pi_{M}$ in such a way that for

$$
\Omega_{A, T}^{M}(\lambda):=\left\{\forall t \in[0, T], \forall i \in I_{A}^{\lambda}, \Delta N_{a_{\lambda} t}^{M, \lambda}(i) \neq 0 \text { iff } \pi_{M}\left(\{t\} \times i_{\lambda}\right) \neq 0\right\}
$$

there holds $\operatorname{Pr}\left[\Omega_{A, T}^{M}(\lambda)\right] \geq 1-\frac{1}{4} \varepsilon$. We now fix $\delta>0$ such that

$$
\delta<c / 4 \quad \text { and } \quad \delta<a /(4 A K p)
$$

Proposition 3.5.3 tells us how to couple, for all $\lambda>0$ small enough, a family of i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes $\left(N_{t}^{S}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ with $\pi_{S}$ in such a way that for

$$
\begin{array}{r}
\Omega_{A, T, \delta}^{S}(\lambda)=\bigcap_{i \in I_{A}^{\lambda}}\left(\left\{\pi_{S}\left(i_{\lambda}\right)=0, \inf _{t \in[0, T-\delta]}\left[N_{a_{\lambda}(t+\delta)}^{S}(i)-N_{a_{\lambda} t}^{S}(i)\right]>0\right\}\right. \\
\left.\cup\left\{\pi_{S}\left(i_{\lambda}\right)=1, N_{a_{\lambda} T}^{S}(i)=0\right\}\right)
\end{array}
$$

there holds $\operatorname{Pr}\left[\Omega_{A, T, \delta}^{S}(\lambda)\right] \geq 1-\frac{1}{4} \varepsilon$.
Step 3. - We consider $\pi_{M}, \pi_{S},\left(N_{t}^{S}(i)\right)_{t \geq 0, i \in \mathbb{Z}\}}$ and $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}\}}$ coupled as in step 2. Then we build the corresponding $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ and the associated rescaled clusters $\left(D_{t}^{\lambda}(x)\right)_{t \geq 0, x \in \mathbb{R}}$, see $(2.2 .3)$ and we build the LFF $(0)$ process associated to $\pi_{S}$ and the corresponding clusters $\left(D_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$. We will work on the event

$$
\Omega_{\lambda}=\Omega_{A}^{S, 1} \cap \Omega_{K, c} \cap \Omega_{A, T}^{M}(\lambda) \cap \Omega_{A, T, \delta}^{S}(\lambda)
$$

We know that for all $\lambda>0$ small enough, $\operatorname{Pr}\left[\Omega_{\lambda}\right] \geq 1-\varepsilon$. We introduce

$$
\mathcal{S}=\bigcup_{t \in \mathcal{T}_{M}}[t, t+\delta]
$$

We will prove in the next step that on $\Omega_{\lambda}$, for all $\lambda>0$ small enough, for all $k \in\{1, \ldots, p\}$, for all $t \in[0, T] \backslash \mathcal{S}$,

$$
\begin{equation*}
\boldsymbol{\delta}\left(D_{t}^{\lambda}\left(x_{k}\right), D_{t}\left(x_{k}\right)\right) \leq 4 / \boldsymbol{n}_{\lambda}+2 A \mathbb{1}_{\{t \in \mathcal{S}\}} \tag{3.5.2}
\end{equation*}
$$

which will imply that

$$
\boldsymbol{\delta}_{T}\left(D^{\lambda}\left(x_{k}\right), D\left(x_{k}\right)\right) \leq 4 T / \boldsymbol{n}_{\lambda}+2 A|\mathcal{S}|
$$

This will conclude the proof, since for $k=1, \ldots, p, t_{k} \notin \mathcal{S}$ (recall $\Omega_{K, c}$ and that $\delta<c$ ) and since the Lebesgue measure of $\mathcal{S}$ is smaller than $K \delta$ (recall $\Omega_{K, c}$ and that $\delta<c$ ). Thus (3.5.2) implies, since $\delta<a /(4 A K p)$,

$$
\begin{aligned}
\sum_{k=1}^{p} \boldsymbol{\delta}_{T}\left(D^{\lambda}\left(x_{k}\right), D\left(x_{k}\right)\right)+\sum_{k=1}^{p} \boldsymbol{\delta}\left(D_{t_{k}}^{\lambda}\left(x_{k}\right), D_{t_{k}}\left(x_{k}\right)\right) & \leq p\left[4 T / \boldsymbol{n}_{\lambda}+2 A K \delta+4 / \boldsymbol{n}_{\lambda}\right] \\
& \leq a / 2+4 p(T+1) / \boldsymbol{n}_{\lambda}
\end{aligned}
$$

which is smaller than $a$ for all $\lambda>0$ small enough. Thus (3.5.1) holds for all $\lambda>0$ small enough.

Step 4. - It remains to check (3.5.2). In the whole step, we work on $\Omega_{\lambda}$. Let thus $k \in\{1, \ldots, p\}$ be fixed. Consider the first marks $\chi_{g}, \chi_{d}$ of $\pi_{S}$ on the left and right of $x_{k}$. Then by definition, we have $D_{t}\left(x_{k}\right)=\left[\chi_{g}, \chi_{d}\right]$ for all $t \in[0, T]$. By $\Omega_{A}^{S, 1}$ and since $x_{k} \in(-B, B)$, we know that $-A<\chi_{g}<\chi_{d}<A$. Define

$$
g_{\lambda}=\left\lfloor\boldsymbol{n}_{\lambda} \chi_{g}\right\rfloor \quad \text { and } \quad d_{\lambda}=\left\lfloor\boldsymbol{n}_{\lambda} \chi_{d}\right\rfloor .
$$

Due to $\Omega_{A, T, \delta}^{S}(\lambda)$ and since $\pi_{S}\left(\left\{\chi_{g}\right\}\right)=\pi_{S}\left(\left\{\chi_{d}\right\}\right)=1$ and $\pi_{S}\left(\left(\chi_{g}, \chi_{d}\right)\right)=0$ by construction, we know that
(i) $N_{a_{\lambda} T}^{S}\left(g_{\lambda}\right)=N_{a_{\lambda} T}^{S}\left(d_{\lambda}\right)=0$ (because $\chi_{g} \in\left(g_{\lambda}\right)_{\lambda}$ and $\left.\chi_{d} \in\left(d_{\lambda}\right)_{\lambda}\right)$;
(ii) for all $i \in \llbracket g_{\lambda}+1, d_{\lambda}-1 \rrbracket, \inf _{t \in[0, T-\delta]}\left[N_{a_{\lambda}(t+\delta)}^{S}(i)-N_{a_{\lambda} t}^{S}(i)\right]>0$ (because $\left.i_{\lambda} \subset\left(\chi_{g}, \chi_{d}\right)\right)$.
Observe now that for $\lambda>0$ small enough (it suffices that $1 / \boldsymbol{n}_{\lambda}<c$ ), there holds $g_{\lambda}<\left\lfloor x_{k} \boldsymbol{n}_{\lambda}\right\rfloor<d_{\lambda}$ (use that $\chi_{g}, \chi_{d} \in \mathcal{X}_{S}$ and that $\chi_{g}<x_{k}<\chi_{d}$ so that due to $\Omega_{K, c}$, $\left.\chi_{g}+c<x_{k}<\chi_{d}-c\right)$.

Point (i) implies that $\eta_{\boldsymbol{a}_{\lambda} t}^{\lambda}\left(g_{\lambda}\right)=\eta_{a_{\lambda} t}^{\lambda}\left(d_{\lambda}\right)=0$ for all $t \in\left[0, \boldsymbol{a}_{\lambda} T\right]$. Consequently, for all $t \in[0, T]$, there holds $C\left(\eta_{a_{\lambda}}^{\lambda},\left\lfloor x_{k} \boldsymbol{n}_{\lambda}\right\rfloor\right) \subset \llbracket g_{\lambda}+1, d_{\lambda}-1 \rrbracket$. This implies that $D_{t}^{\lambda}\left(x_{k}\right) \subset\left[\left(g_{\lambda}+1\right) / \boldsymbol{n}_{\lambda},\left(d_{\lambda}-1\right) / \boldsymbol{n}_{\lambda}\right] \subset\left[\chi_{g}, \chi_{d}\right]$. Recalling that $D_{t}\left(x_{k}\right)=\left[\chi_{g}, \chi_{d}\right]$ and that $-A<\chi_{g}<\chi_{d}<A$, we deduce that

$$
\boldsymbol{\delta}\left(D_{t}\left(x_{k}\right), D_{t}^{\lambda}\left(x_{k}\right)\right) \leq 2 A \quad \text { for all } t \in[0, T]
$$

Another consequence is that the matches falling outside $\llbracket g_{\lambda}, d_{\lambda} \rrbracket$ (and a fortiori outside $I_{A}^{\lambda}$ ) have no influence on $\left\lfloor x_{k} \boldsymbol{n}_{\lambda}\right\rfloor$ during $\left[0, \boldsymbol{a}_{\lambda} T\right]$.

It only remains to check that for $t \in[0, T] \backslash \mathcal{S}$, if $\lambda>0$ is small enough, $\boldsymbol{\delta}\left(D_{t}\left(x_{k}\right), D_{t}^{\lambda}\left(x_{k}\right)\right) \leq 4 / \boldsymbol{n}_{\lambda}$. We thus fix $t \in[0, T] \backslash \mathcal{S}$ and consider

$$
t_{0}=\max \left\{s \in \mathcal{T}_{M}: s<t\right\}
$$

Then by definition of $\mathcal{S}, t-t_{0}>\delta$. Consequently, point (ii) guarantees us that

$$
\forall i \in \llbracket g_{\lambda}+1, d_{\lambda}-1 \rrbracket, \quad N_{a_{\lambda} t}^{S}-N_{a_{\lambda} t_{0}}^{S}>0
$$

A seed falls on each of these sites during $\left[\boldsymbol{a}_{\lambda} t_{0}, \boldsymbol{a}_{\lambda} t\right]$. Furthermore, there are no matches falling on $\llbracket g_{\lambda}+1, d_{\lambda}-1 \rrbracket$ during $\left[\boldsymbol{a}_{\lambda} t_{0}, \boldsymbol{a}_{\lambda} t\right]$, by definition of $t_{0}$ and due to $\Omega_{A, T}^{M}(\lambda)$. Consequently, we have $\eta_{a_{\lambda} t}^{\lambda}(i)=1$ for all $i \in \llbracket g_{\lambda}+1, d_{\lambda}-1 \rrbracket$. All this implies that $C\left(\eta_{a_{\lambda} t}^{\lambda},\left\lfloor x_{k} \boldsymbol{n}_{\lambda}\right\rfloor\right)=\llbracket g_{\lambda}+1, d_{\lambda}-1 \rrbracket$, whence

$$
D_{t}^{\lambda}\left(x_{k}\right)=\left[\left(g_{\lambda}+1\right) / \boldsymbol{n}_{\lambda},\left(d_{\lambda}-1\right) / \boldsymbol{n}_{\lambda}\right]=\left[\left(\left\lfloor\boldsymbol{n}_{\lambda} \chi_{g}\right\rfloor+1\right) / \boldsymbol{n}_{\lambda},\left(\left\lfloor\boldsymbol{n}_{\lambda} \chi_{d}\right\rfloor-1\right) / \boldsymbol{n}_{\lambda}\right] .
$$

Recalling that $D_{t}\left(x_{k}\right)=\left[\chi_{g}, \chi_{d}\right]$, we easily conclude.

### 3.6. Well-posedness of the limit process when $\beta \in\{\infty, B S\}$

The aim of this section is to prove Theorems 2.3.2 and 2.4.3, and to localize the limit processes. All the results below have already been proved in [15] for the $\operatorname{LFF}(\infty)$ process. We provide here a consequently simpler proof, that allows us to treat simultaneously the cases $\beta=B S$ and $\beta=\infty$.

Remark 3.6.1. - Under $\left(H_{S}(\infty)\right)$, we put $\theta_{u}=\delta_{u}$ and $F_{S}(u, v)=u$ for all $u \in[0,1]$, all $v \in[0,1]$. Using this function $F_{S}$, the $\operatorname{LFF}(B S)$-process is nothing but the $\operatorname{LFF}(\infty)$-process.

We consider a Poisson measure $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x, \mathrm{~d} v)$ on $[0, \infty) \times \mathbb{R} \times[0,1]$ with intensity measure $\mathrm{d} t \mathrm{~d} x \mathrm{~d} v$ and abusively write $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)=\int_{v \in[0,1]} \pi_{M}(\mathrm{~d} t, \mathrm{~d} x, \mathrm{~d} v)$, which is a Poisson measure on $[0, \infty) \times \mathbb{R}$ with intensity measure $\mathrm{d} t \mathrm{~d} x$.

Definition 3.6.2. - Let $\beta \in\{\infty, B S\}$. If $\beta=\infty$, consider $F_{S}$ as in Remark 3.6.1. If $\beta=B S$, consider $F_{S}$ as in Definition 2.4.1. Let $A>0$ be fixed. $A \mathbb{R}_{+} \times \mathcal{I} \times \mathbb{R}_{+}$-valued process $\left(Z_{t}^{A}(x), D_{t}^{A}(x), H_{t}^{A}(x)\right)_{t \geq 0, x \in[-A, A]}$ such that a.s., for all $x \in[-A, A],\left(Z_{t}^{A}(x), H_{t}^{A}(x)\right)_{t \geq 0}$ is càdlàg, is called a $\operatorname{LFF}_{A}(\beta)$-process if a.s., for all $t \geq 0$, all $x \in[-A, A]$,

$$
\begin{aligned}
Z_{t}^{A}(x) & =\int_{0}^{t} \mathbb{1}_{\left\{Z_{s}^{A}(x)<1\right\}} \mathrm{d} s-\int_{0}^{t} \int_{[-A, A]} \mathbb{1}_{\left\{Z_{s-}^{A}(x)=1, y \in D_{s-}^{A}(x)\right\}} \pi_{M}(\mathrm{~d} s, \mathrm{~d} y) \\
H_{t}^{A}(x) & =\int_{0}^{t} \int_{0}^{1} F_{S}\left(Z_{s-}^{A}(x), v\right) \mathbb{1}_{\left\{Z_{s-}^{A}(x)<1\right\}} \pi_{M}(\mathrm{~d} s \times\{x\} \times \mathrm{d} v)-\int_{0}^{t} \mathbb{1}_{\left\{H_{s}^{A}(x)>0\right\}} \mathrm{d} s,
\end{aligned}
$$

where $D_{t}^{A}(x)=\left[L_{t}^{A}(x), R_{t}^{A}(x)\right]$, with

$$
\left\{\begin{array}{l}
L_{t}^{A}(x)=(-A) \vee \sup \left\{y \in[-A, x] ; Z_{t}^{A}(y)<1 \text { or } H_{t}^{A}(y)>0\right\}  \tag{3.6.1}\\
R_{t}^{A}(x)=A \wedge \inf \left\{y \in[x, A] ; Z_{t}^{A}(y)<1 \text { or } H_{t}^{A}(y)>0\right\}
\end{array}\right.
$$

and where $D_{t-}^{A}(x)$ is defined similarly.
Observe that for $\beta \in\{\infty, B S\}$, for any $A>0$, the $\operatorname{LFF}_{A}(\beta)$-process is obviously well and uniquely defined and can be built as follows.

Algorithm 3.6.3. - Consider the marks $\left(T_{k}, X_{k}, V_{k}\right)_{k=1, \ldots, n}$ of $\pi_{M}$ in $[0, T] \times$ $[-A, A] \times[0,1]$, ordered chronologically and set $T_{0}=0$.

Step 0. - Put $Z_{0}^{A}(x)=H_{0}^{A}(x)=0$ and $D_{0}^{A}(x)=\{x\}$ for all $x \in[-A, A]$. Assume that for some $k \in\{0, \ldots, n-1\}$,

$$
\left(Z_{t}^{A}(x), D_{t}^{A}(x), H_{t}^{A}(x)\right)_{t \in\left[0, T_{k}\right], x \in[-A, A]}
$$

has been built.
Step $k+1$. - Then for $t \in\left(T_{k}, T_{k+1}\right)$ and $x \in[-A, A]$, put

$$
Z_{t}^{A}(x)=\min \left(1, Z_{T_{k}}^{A}(x)+t-T_{k}\right),
$$

set $H_{t}^{A}(x)=\max \left(0, H_{T_{k}}^{A}(x)-t+T_{k}\right)$ and then define $D_{t}^{A}(x)$ as in (3.6.1). Finally, build $\left(Z_{T_{k+1}}^{A}(x), D_{T_{k+1}}^{A}(x), H_{T_{k+1}}^{A}(x)\right)$ as follows.
$\triangleright$ If $Z_{T_{k+1}-}^{A}\left(X_{k+1}\right)=1$, set $H_{T_{k+1}}^{A}(x)=H_{T_{k+1}-}^{A}(x)$ for all $x \in[-A, A]$ and consider $[a, b]:=D_{T_{k+1}-}^{A}\left(X_{k+1}\right)$. Set

$$
\begin{aligned}
& Z_{T_{k+1}}^{A}(x)=\left\{\begin{array}{ll}
0 & \text { for all } x \in(a, b), \\
Z_{T_{k+1}-}^{A}(x) & \text { for all } x \in[-A, A] \backslash[a, b] . \\
Z_{T_{k+1}}^{A}(a)= \begin{cases}0 & \text { if } Z_{T_{k+1}-}^{A}(a)=1, \\
Z_{T_{k+1}-}^{A}(a) & \text { if } Z_{T_{k+1}-}^{A}(a)<1,\end{cases} \\
Z_{T_{k+1}}^{A}(b)= \begin{cases}0 & \text { if } Z_{T_{k+1}-}^{A}(b)=1, \\
Z_{T_{k+1}-}^{A}(b) & \text { if } Z_{T_{k+1}-}^{A}(b)<1 .\end{cases}
\end{array} . . \begin{array}{l}
A \\
A
\end{array},\right.
\end{aligned}
$$

$\triangleright$ If $Z_{T_{k+1}-}^{A}\left(X_{k+1}\right)<1$, set

$$
H_{T_{k+1}}^{A}\left(X_{k+1}\right)=F_{S}\left(Z_{T_{k+1}-}^{A}\left(X_{k+1}\right), V_{k+1}\right),
$$

put $Z_{T_{k+1}}^{A}\left(X_{k+1}\right)=Z_{T_{k+1}-}^{A}\left(X_{k+1}\right)$ and

$$
\left(Z_{T_{k+1}}^{A}(x), H_{T_{k+1}}^{A}(x)\right)=\left(Z_{T_{k+1}-}^{A}(x), H_{T_{k+1}-}^{A}(x)\right)
$$

for all $x \in[-A, A] \backslash\left\{X_{k+1}\right\}$.
$\triangleright$ Using the values of $\left(Z_{T_{k+1}}^{A}(x), H_{T_{k+1}}^{A}(x)\right)_{x \in[-A, A]}$, compute $\left(D_{T_{k+1}}^{A}(x)\right)_{x \in[-A, A]}$ as in (3.6.1).

We now state a refined version of Theorems 2.3.2 and 2.4.3.
Proposition 3.6.4. - Let $\beta \in\{\infty, B S\}$. Let $\pi_{M}$ be a Poisson measure on $[0, \infty) \times \mathbb{R} \times[0,1]$ with intensity measure $\mathrm{d} t \mathrm{~d} x \mathrm{~d} v$.
(i) There exists a unique $\operatorname{LFF}(\beta)$-process $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$.
(ii) It can be perfectly simulated on $[0, T] \times[-n, n]$ for any $T>0$, any $n>0$.
(iii) For $A>0$, let $\left(Z_{t}^{A}(x), D_{t}^{A}(x), H_{t}^{A}(x)\right)_{t \geq 0, x \in[-A, A]}$ be the unique $\operatorname{LFF}_{A}(\beta)$ process. There holds

$$
\begin{align*}
& \operatorname{Pr}\left[\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \in[0, T], x \in[-A / 2, A / 2]}\right.  \tag{3.6.2}\\
& \left.\quad=\left(Z_{t}^{A}(x), D_{t}^{A}(x), H_{t}^{A}(x)\right)_{t \in[0, T], x \in[-A / 2, A / 2]}\right] \geq 1-C_{T} \mathrm{e}^{-\alpha_{T} A},
\end{align*}
$$

for some constants $\alpha_{T}>0$ and $C_{T}>0$ not depending on $A>0$.
To prove this result, we need a lower-bound of the length of the barriers.
Lemma 3.6.5. - Let $\beta \in\{\infty, B S\}$. If $\beta=\infty$, consider $F_{S}$ as in Remark 3.6.1. If $\beta=B S$, consider $F_{S}$ as in Definition 2.4.1. There exists $v_{0} \in[0,1)$ such that for all $z \in\left[\frac{3}{4}, 1\right)$, all $v \in\left[v_{0}, 1\right], F(z, v) \geq \frac{1}{2}$.

Proof. - If $\beta=\infty$, the result is obvious with $v_{0}=0$, since $F_{S}(z, v)=z \geq \frac{1}{2}$ for all $z \in\left[\frac{1}{2}, 1\right], v \in[0,1]$. Consider now the case $\beta=B S$. First observe that

$$
g_{S}(t, s) \leq \operatorname{Pr}\left[N_{T_{S}(t+s)}^{S}-N_{T_{S} t}^{S}>0\right]=\nu_{S}\left(\left[0, T_{S} s\right]\right)
$$

Hence for all $z \in\left[\frac{3}{4}, 1\right)$,

$$
\begin{aligned}
\theta_{z}\left(\left[0, \frac{1}{2}\right)\right) & \leq \nu_{S}\left(\left[\frac{3}{4} T_{S}, T_{S}\right]\right)+\frac{\nu_{S}\left(\left[\frac{3}{4} T_{S}, T_{S}\right]\right)^{2}}{\nu_{S}\left(\left[\frac{1}{2} T_{S}, T_{S}\right]\right)^{2}} \nu_{S}\left(\left[0, \frac{1}{2} T_{S}\right]\right) \\
& \leq \nu_{S}\left(\left[0, \frac{1}{2} T_{S}\right] \cup\left[\frac{3}{4} T_{S}, T_{S}\right]\right)=: v_{0}<1
\end{aligned}
$$

since $\operatorname{supp} \nu_{S}=\left[0, T_{S}\right]$. We deduce that for $z \in\left[\frac{3}{4}, 1\right]$,

$$
\int_{0}^{1} \mathrm{~d} v \mathbb{1}_{\left\{F_{S}(z, v)<\frac{1}{2}\right\}}=\theta_{z}\left(\left[0, \frac{1}{2}\right)\right) \leq v_{0}
$$

Recalling that $v \mapsto F_{S}(z, v)$ is nondecreasing, we deduce that $F_{S}(z, v) \geq \frac{1}{2}$ for $v \in\left[v_{0}, 1\right]$.

Proof of Proposition 3.6.4. - We split the proof into steps. We work on $[0, T]$.
Step 1. - We observe that for a mark $(\tau, X, V)$ of $\pi_{M}$ with $X \in[-A, A]$ and $V \geq v_{0}$ (see Lemma 3.6.5), we have $H_{t}^{A}(X)>0$ or $Z_{t}^{A}(X)<1$ for all $t \in\left[\tau, \tau+\frac{1}{4}\right]$ (and the same result applies to the $\operatorname{LFF}(\beta)$-process if it exists).

Indeed, assume first that $Z_{\tau-}^{A}(X) \in\left[0, \frac{3}{4}\right)$. Then for $t \in\left[\tau, \tau+\frac{1}{4}\right]$,

$$
Z_{t}^{A}(X)=Z_{\tau-}^{A}(X)+t-\tau<1
$$

Assume next that $Z_{\tau-}^{A}(X) \in\left[\frac{3}{4}, 1\right)$. Then

$$
H_{\tau}(X)=F_{S}\left(Z_{\tau-}^{A}(X), V\right) \geq \frac{1}{2}
$$

due to Lemma 3.6.5, so that for $t \in\left[\tau, \tau+\frac{1}{2}\right) \supset\left[\tau, \tau+\frac{1}{4}\right]$

$$
H_{t}(X)=H_{\tau}(X)-t+\tau>0
$$

If finally $Z_{\tau-}^{A}(X)=1$, then $Z_{\tau}^{A}(X)=0$, whence, for $t \in[\tau, \tau+1) \supset\left[\tau, \tau+\frac{1}{4}\right]$

$$
Z_{t}^{A}(X)=t-\tau<1
$$

Step 2. - For $a \in \mathbb{R}$, we consider the event $\Omega_{a}$ defined as follows: for $\left\{\left(T_{k}, X_{k}, V_{k}\right)\right\}_{k=1, \ldots, n}$ the marks of $\pi_{M}$ restricted to $[0, T] \times[a, a+1) \times\left[v_{0}, 1\right]$ ordered chronologically, for $T_{0}=0, T_{n+1}=T$, we put

$$
\Omega_{a}=\left\{\max _{i=0, \ldots, n}\left(T_{i+1}-T_{i}\right)<\frac{1}{4}\right\}
$$

We immediately deduce from step 1 that for any $a \in \mathbb{R}$, any $A>|a|+1$,

$$
\Omega_{a} \subset\left\{\forall t \in[0, T], \exists x \in(a, a+1), H_{t}^{A}(x)>0 \text { or } Z_{t}^{A}(x)<1\right\}
$$

Thus on $\Omega_{a}$, clusters on the left of $a$ cannot be connected to clusters on the right of $a+1$ during $[0, T]$. Hence matches falling at the right of $a+1$ (resp. on the left of $a$ ) do not affect the zone $(-\infty, a)$ (resp. $(a+1, \infty)$ ) during $[0, T]$.

Step 3. - Obviously, $q_{T}:=\operatorname{Pr}\left(\Omega_{a}\right)$ is positive and does not depend on $a$. Furthermore, $\Omega_{a}$ is independent of $\Omega_{b}$ for all $a, b \in \mathbb{Z}$ with $a \neq b$. Hence there are a.s. infinitely many $a \in \mathbb{Z}$ such that $\Omega_{a}$ is realized.

Then it is routine to deduce the well-posedness of the $\operatorname{LFF}(\beta)$-process. The perfect simulation algorithm on a finite-box $[0, T] \times[-n, n]$ is also easy: simulate $\pi_{M}$ on $[0, T] \times\left[a_{1}, a_{2}\right]$ in such a way that $\Omega_{a_{1}} \cap \Omega_{a_{2}}$ is realized and that $a_{1}+1<-n<n<a_{2}$. Then apply the same rules as for the $\operatorname{LFF}_{A}(\beta)$-process. This will give the true $\operatorname{LFF}(\beta)$ process inside $\left[a_{1}+1, a_{2}\right] \supset[-n, n]$, because matches falling outside $\left[a_{1}, a_{2}+1\right]$ have no effect on the process in the box $\left[a_{1}+1, a_{2}\right]$ during $[0, T]$.

Finally, we can clearly bound from below the left hand side of (3.6.2) by

$$
\begin{aligned}
\operatorname{Pr}\left[\left(\bigcup_{a \in\left[-A,-\frac{1}{2} A-1\right] \cap \mathbb{Z}} \Omega_{a}\right) \cap\left(\bigcup_{a \in\left[\frac{1}{2} A, A-1\right] \cap \mathbb{Z}} \Omega_{a}\right)\right] & \geq 1-2 \operatorname{Pr}\left[\Omega_{0}^{c}\right]^{\lfloor A\rfloor-\left\lfloor\frac{1}{2} A\right\rfloor-2} \\
& \geq 1-2\left(1-q_{T}\right)^{\frac{1}{2} A-4},
\end{aligned}
$$

whence (3.6.2) with $C_{T}=2 /\left(1-q_{T}\right)^{4}$ and $\alpha_{T}=-\frac{1}{2} \log \left(1-q_{T}\right)$.

### 3.7. Localization of the discrete processes when $\beta \in\{\infty, B S\}$

We recall that $\boldsymbol{a}_{\lambda}, \boldsymbol{n}_{\lambda}$ and $\boldsymbol{m}_{\lambda}$ are defined in (2.2.1), (2.2.2) and (2.2.4). For $A>0$ and $i \in \mathbb{Z}$, we set

$$
A_{\lambda}=\left\lfloor A \boldsymbol{n}_{\lambda}\right\rfloor, \quad I_{A}^{\lambda}=\llbracket-A_{\lambda}, A_{\lambda} \rrbracket, \quad i_{\lambda}=\left[i / \boldsymbol{n}_{\lambda},(i+1) / \boldsymbol{n}_{\lambda}\right) .
$$

For $\eta \in\{0,1\}^{I_{A}^{\lambda}}$ and $i \in I_{A}^{\lambda}$, we define the occupied connected component around $i$ as

$$
C_{A}(\eta, i)= \begin{cases}\varnothing & \text { if } \eta(i)=0, \\ \llbracket \ell_{A}(\eta, i), r_{A}(\eta, i) \rrbracket & \text { if } \eta(i)=1,\end{cases}
$$

where

$$
\begin{gathered}
\ell_{A}(\eta, i)=\left(-A_{\lambda}\right) \vee(\sup \{k<i: \eta(k)=0\}+1) \\
r_{A}(\eta, i)=A_{\lambda} \wedge(\inf \{k>i: \eta(k)=0\}-1)
\end{gathered}
$$

Definition 3.7.1. - Assume $\left(H_{M}\right)$ and $\left(H_{S}(\beta)\right)$ with $\beta \in\{\infty, B S\}$. Let $\lambda \in(0,1]$ and $A>0$ be fixed. For each $i \in I_{A}^{\lambda}$, we consider a $\operatorname{SR}\left(\mu_{S}\right)$-process $\left(N_{t}^{S}(i)\right)_{t \geq 0}$ and a $\operatorname{SR}\left(\mu_{M}^{\lambda}\right)$-process $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0}$, all these processes being independent. Consider a $\{0,1\}$-valued process $\left(\eta_{t}^{\lambda, A}(i)\right)_{i \in I_{A}^{\lambda}, t \geq 0}$ such that a.s., for all $i \in I_{A}^{\lambda}$, $\left(\eta_{t}^{\lambda, A}(i)\right)_{t \geq 0}$ is càdlàg. We say that $\left(\eta_{t}^{\lambda, A}(i)\right)_{i \in I_{A}^{\lambda}, t \geq 0}$ is a $\mathrm{FF}_{A}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process if a.s., for all $i \in I_{A}^{\lambda}$, all $t \geq 0$,

$$
\eta_{t}^{\lambda, A}(i)=\int_{0}^{t} \mathbb{1}_{\left\{\eta_{s-}^{\lambda, A}(i)=0\right\}} \mathrm{d} N_{s}^{S}(i)-\sum_{j \in I_{A}^{\lambda}} \int_{0}^{t} \mathbb{1}_{\left\{j \in C_{A}\left(\eta_{s-}^{\lambda, A}, i\right)\right\}} \mathrm{d} N_{s}^{M, \lambda}(j) .
$$

For $x \in[-A, A]$ and $t \geq 0$, we introduce

$$
\begin{align*}
D_{t}^{\lambda, A}(x) & =\frac{1}{\boldsymbol{n}_{\lambda}} C_{A}\left(\eta_{a_{\lambda} t}^{\lambda, A},\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor\right) \subset\left[-A_{\lambda} / \boldsymbol{n}_{\lambda}, A_{\lambda} / \boldsymbol{n}_{\lambda}\right] \simeq[-A, A],  \tag{3.7.1}\\
K_{t}^{\lambda, A}(x) & =\frac{\left|\left\{i \in \llbracket\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor-\boldsymbol{m}_{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor+\boldsymbol{m}_{\lambda} \rrbracket \cap I_{A}^{\lambda}: \eta_{\boldsymbol{a}_{\lambda} t}^{\lambda, A}(x)=1\right\}\right|}{\left|\llbracket\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor-\boldsymbol{m}_{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor+\boldsymbol{m}_{\lambda} \rrbracket \cap I_{A}^{\lambda}\right|} \in[0,1], \\
Z_{t}^{\lambda, A}(x) & =\frac{\psi_{S}\left(K_{t}^{\lambda, A}(x)\right)}{\boldsymbol{a}_{\lambda}} \wedge 1 \in[0,1] . \tag{3.7.2}
\end{align*}
$$

We generalize [15, Proposition 11], with a consequently less intricate proof.
Proposition 3.7.2. - Assume $\left(H_{M}\right)$ and $\left(H_{S}(\beta)\right)$, for some $\beta \in\{\infty, B S\}$. Let $T>0$ and $\lambda \in(0,1)$. For each $i \in \mathbb{Z}$, we consider a $\operatorname{SR}\left(\mu_{S}\right)$-process $\left(N_{t}^{S}(i)\right)_{t \geq 0}$ and a $\operatorname{SR}\left(\mu_{M}^{\lambda}\right)$-process $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0}$, all these processes being independent. Let $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ be the corresponding $\mathrm{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process, and for each $A>0$, let $\left(\eta_{t}^{\lambda, A}(i)\right)_{t \geq 0, i \in I_{A}^{\lambda}}$ be the corresponding $\mathrm{FF}_{A}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process. Recall (2.2.3)-(2.2.5) and (3.7.1)-(3.7.2). There are some constants $\alpha_{T}>0$ and $C_{T}>0$ such that for all $A \geq 1$, all $\lambda \in(0,1]$ small enough,

$$
\begin{aligned}
& \operatorname{Pr}\left[\left(\eta_{t}^{\lambda}(i)\right)_{t \in\left[0, a_{\lambda} T\right], i \in I_{A / 2}^{\lambda}}=\left(\eta_{t}^{\lambda, A}(i)\right)_{t \in\left[0, a_{\lambda} T\right], i \in I_{A / 2}^{\lambda}}\right. \\
&\left(Z_{t}^{\lambda}(x), D_{t}^{\lambda}(x)\right)_{t \in[0, T], x \in\left[-\frac{1}{2} A, \frac{1}{2} A\right]}\left.=\left(Z_{t}^{\lambda, A}(x), D_{t}^{\lambda, A}(x)\right)_{t \in[0, T], x \in\left[-\frac{1}{2} A, \frac{1}{2} A\right]}\right] \\
& \geq 1-C_{T} \mathrm{e}^{-\alpha_{T} A}
\end{aligned}
$$

Proof in the case where $\beta=\infty$. - It of course suffices to prove the result for all $A$ large enough (we will assume that $A>8 T$ ). We consider the true $\mathrm{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. For $a \in \mathbb{R}$, we introduce

$$
J_{a}^{\lambda}:=\left[\left[\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor,\left\lfloor(a+1) \boldsymbol{n}_{\lambda}\right\rfloor-1\right]\right] .
$$

Step 1. - We show here that for all $a \in \mathbb{R}$, there exists an event $\Omega_{a, 0}^{\lambda}$, depending only on $\left(N_{s}^{S}(i), N_{s}^{M, \lambda}(i)\right)_{i \in J_{a}^{\lambda}, s \in\left[0,3 a_{\lambda} / 4\right]}$ such that
(i) on $\Omega_{a, 0}^{\lambda}$, a.s., there is $i \in J_{a}^{\lambda}$ such that $\eta_{a_{\lambda} s}^{\lambda}(i)=0$ for all $s \in\left[0, \frac{3}{4}\right]$;
(ii) $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\Omega_{a, 0}^{\lambda}\right]=1$.

This is very easy: consider simply $\Omega_{a, 0}^{\lambda}=\left\{\exists i \in J_{a}^{\lambda}, N_{3 a_{\lambda} / 4}^{S}(i)=0\right\}$. Clearly, point (i) is satisfied, since there is a site of $J_{a}^{\lambda}$ on which no seed falls during $\left[0, \frac{3}{4} \boldsymbol{a}_{\lambda}\right]$. Since $\left|J_{a}^{\lambda}\right|=\boldsymbol{n}_{\lambda} \sim 1 /\left(\lambda \boldsymbol{a}_{\lambda}\right)=1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)$, we deduce from $\left(H_{S}(\infty)\right)$ that

$$
\begin{aligned}
\operatorname{Pr}\left[\Omega_{a, 0}^{\lambda}\right] & =1-\nu_{S}\left(\left(0, \frac{3}{4} \boldsymbol{a}_{\lambda}\right)\right)^{n_{\lambda}}=1-\left(1-\nu_{S}\left(\left(\frac{3}{4} \boldsymbol{a}_{\lambda}, \infty\right)\right)\right)^{n_{\lambda}} \\
& \simeq 1-\mathrm{e}^{-\nu_{S}\left(\left(\frac{3}{4} a_{\lambda}, \infty\right)\right) / \nu_{S}\left(\left(a_{\lambda}, \infty\right)\right)} \longrightarrow 1
\end{aligned}
$$

as $\lambda \rightarrow 0$, whence (ii).
Step 2. - We now check that for all $a \in \mathbb{R}$, all $t \geq \frac{1}{2}$, there exists an event $\Omega_{a, t}^{\lambda}$, depending only on $\left(N_{s}^{S}(i), N_{s}^{M, \lambda}(i)\right)_{i \in J_{a}^{\lambda}, s \in\left[\left(t-\frac{1}{2}\right) a_{\lambda},\left(t+\frac{1}{4}\right) a_{\lambda}\right]}$ such that

Figure 7. The event $\Omega_{a, t}^{\lambda}$.
A match falls on $i_{M}$ at time $t_{M}$, no seed fall on $j_{g}$ and $j_{d}$ during $\left[\boldsymbol{a}_{\lambda}\left(t-\frac{1}{2}\right), \boldsymbol{a}_{\lambda}\left(t+\frac{1}{4}\right)\right]$. All the sites of $\llbracket i_{M}-\boldsymbol{k}_{\lambda}, i_{M}+\boldsymbol{k}_{\lambda} \rrbracket$ receive at least one seed during $\left[\boldsymbol{a}_{\lambda}\left(t-\frac{1}{2}\right), \boldsymbol{a}_{\lambda}\left(t-\frac{1}{12}\right)\right]$. Finally, there is at least one site of $\llbracket i_{M}-\boldsymbol{k}_{\lambda}, i_{M}+\boldsymbol{k}_{\lambda} \rrbracket$ on which no seed falls during $\left[\boldsymbol{a}_{\lambda}\left(t-\frac{1}{12}\right), \boldsymbol{a}_{\lambda}\left(t+\frac{1}{4}\right)\right]$.
(i) on $\Omega_{a, t}^{\lambda}$, a.s., there is $i \in J_{a}^{\lambda}$ such that $\eta_{a_{\lambda} s}^{\lambda}(i)=0$ for all $s \in\left[t, t+\frac{1}{4}\right]$;
(ii) $q_{\lambda}:=\operatorname{Pr}\left[\Omega_{a, t}^{\lambda}\right]$ does not depend on $t, a$ and $q:=\liminf _{\lambda \rightarrow 0} q_{\lambda}>0$.

This is much more delicate. We put

$$
\boldsymbol{k}_{\lambda}=\left\lfloor 1 / \nu_{S}\left(\left(\frac{3}{8} \boldsymbol{a}_{\lambda}, \infty\right)\right)\right\rfloor .
$$

Observe that due to $\left(H_{S}(\infty)\right), \boldsymbol{k}_{\lambda} \ll \boldsymbol{n}_{\lambda}=\left\lfloor 1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)\right\rfloor$
We introduce the event $\Omega_{a, t}^{\lambda}$ on which (see Figure 7):
(a) we have $\Delta N_{t_{M}}^{M, \lambda}\left(i_{M}\right)>0$ for some $i_{M} \in \llbracket\left\lfloor\left(a+\frac{1}{3}\right) \boldsymbol{n}_{\lambda}\right\rfloor,\left\lfloor\left(a+\frac{2}{3}\right) \boldsymbol{n}_{\lambda}\right\rfloor \rrbracket$, some $t_{M}$ in $\left[\left(t-\frac{1}{12}\right) \boldsymbol{a}_{\lambda}, t \boldsymbol{a}_{\lambda}\right]$ and this is the only match falling in $J_{a}^{\lambda}$ during $\left[\left(t-\frac{1}{2}\right) \boldsymbol{a}_{\lambda}, t \boldsymbol{a}_{\lambda}\right]$;
(b) there are $j_{g} \in \llbracket\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor,\left\lfloor\left(a+\frac{1}{4}\right) \boldsymbol{n}_{\lambda}\right\rfloor \rrbracket$ and $j_{d} \in \llbracket\left\lfloor\left(a+\frac{3}{4}\right) \boldsymbol{n}_{\lambda}\right\rfloor,\left\lfloor(a+1) \boldsymbol{n}_{\lambda}-1\right\rfloor \rrbracket$ such that $N_{a_{\lambda}\left(t+\frac{1}{4}\right)}^{S}\left(j_{g}\right)-N_{\boldsymbol{a}_{\lambda}\left(t-\frac{1}{2}\right)}^{S}\left(j_{g}\right)=N_{a_{\lambda}\left(t+\frac{1}{4}\right)}^{S}\left(j_{d}\right)-N_{a_{\lambda}\left(t-\frac{1}{2}\right)}^{S}\left(j_{d}\right)=0$;
(c) for all $i \in \llbracket i_{M}-\boldsymbol{k}_{\lambda}, i_{M}+\boldsymbol{k}_{\lambda} \rrbracket, N_{\boldsymbol{a}_{\lambda}\left(t-\frac{1}{12}\right)}^{S}(i)-N_{\boldsymbol{a}_{\lambda}\left(t-\frac{1}{2}\right)}^{S}(i)>0$;
(d) there is $j_{0} \in \llbracket i_{M}-\boldsymbol{k}_{\lambda}, i_{M}+\boldsymbol{k}_{\lambda} \rrbracket$ such that $N_{a_{\lambda}\left(t+\frac{1}{4}\right)}^{S}\left(j_{0}\right)-N_{a_{\lambda}\left(t-\frac{1}{12}\right)}^{S}\left(j_{0}\right)=0$.

We first prove point (i), considering two cases.
$\triangleright$ If the zone $\llbracket i_{M}-\boldsymbol{k}_{\lambda}, i_{M}+\boldsymbol{k}_{\lambda} \rrbracket$ is completely occupied at time $t_{M}-$, then it burns at time $t_{M}$ and since no seed falls on $j_{0}$, which belongs to this zone, during $\left[t_{M}, \boldsymbol{a}_{\lambda}\left(t+\frac{1}{4}\right)\right] \supset\left[\boldsymbol{a}_{\lambda} t, \boldsymbol{a}_{\lambda}\left(t+\frac{1}{4}\right)\right]$, we deduce that $\eta_{\boldsymbol{a}_{\lambda} s}^{\lambda}\left(j_{0}\right)=0$ for all $s \in\left[t, t+\frac{1}{4}\right]$.
$\triangleright$ Assume now that there is $i_{0} \in \llbracket i_{M}-\boldsymbol{k}_{\lambda}, i_{M}+\boldsymbol{k}_{\lambda} \rrbracket$ that is vacant at time $t_{M}$. Recall that there is no fire in $J_{a}^{\lambda}$ during $\left[\boldsymbol{a}_{\lambda}\left(t-\frac{1}{2}\right), t_{M}\right)$ and that on each site of $\llbracket i_{M}-\boldsymbol{k}_{\lambda}, i_{M}+\boldsymbol{k}_{\lambda} \rrbracket$, at least one seed falls during $\left[\boldsymbol{a}_{\lambda}\left(t-\frac{1}{2}\right), \boldsymbol{a}_{\lambda}\left(t-\frac{1}{12}\right)\right] \subset\left[\boldsymbol{a}_{\lambda}\left(t-\frac{1}{2}\right), t_{M}\right)$. Then necessarily, a fire starting at some $i_{M}^{\prime} \notin J_{a}^{\lambda}$ at some time $t_{M}^{\prime} \in\left[\boldsymbol{a}_{\lambda}\left(t-\frac{1}{2}\right), t_{M}\right)$ has made vacant $i_{0}$. Assume e.g. that $i_{M}^{\prime}<\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor$ and observe that $i_{M}^{\prime}<j_{g}<i_{0}$. The fire $\left(t_{M}^{\prime}, i_{M}^{\prime}\right)$ has then also necessarily made vacant $j_{g}$. Since no seed falls on $j_{g}$ during $\left[\boldsymbol{a}_{\lambda}\left(t-\frac{1}{2}\right), \boldsymbol{a}_{\lambda}\left(t+\frac{1}{4}\right)\right]$, we deduce that $j_{g}$ remains vacant during $\left[t_{M}^{\prime}, \boldsymbol{a}_{\lambda}\left(t+\frac{1}{4}\right)\right] \supset$ $\left[\boldsymbol{a}_{\lambda} t, \boldsymbol{a}_{\lambda}\left(t+\frac{1}{4}\right)\right]$.

We now prove (ii). The quantity $\operatorname{Pr}\left[\Omega_{a, t}^{\lambda}\right]$ does obviously not depend on $a \in \mathbb{R}$ nor on $t \geq \frac{1}{2}$ by invariance by spatial translation and by time stationarity. We infer from Proposition 3.2.1 that for $\pi_{M}(\mathrm{~d} s, \mathrm{~d} x)$ a Poisson measure on $[0, \infty) \times \mathbb{R}$ with intensity measure $\mathrm{d} s \mathrm{~d} x$, the probability of (a) tends, as $\lambda \rightarrow 0$, to

$$
\begin{aligned}
q:=\operatorname{Pr}( & \pi_{M}\left(\left[t-\frac{1}{12}, t\right] \times\left[a+\frac{1}{3}, a+\frac{2}{3}\right]\right)=1 \\
& \left.\pi_{M}\left(\left(\left[t-\frac{1}{2}, t\right] \times[a, a+1]\right) \backslash\left(\left[t-\frac{1}{12}, t\right] \times\left[a+\frac{1}{3}, a+\frac{2}{3}\right]\right)\right)=0\right),
\end{aligned}
$$

which is clearly positive. Next, the probability of $(\mathrm{b})$ tends to 1 . Indeed, treating e.g. the case of $j_{g}$, there holds, recalling that $\boldsymbol{n}_{\lambda} \simeq 1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)$,

$$
\begin{aligned}
\operatorname{Pr}[\exists j & \left.\in \llbracket\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor,\left\lfloor\left(a+\frac{1}{4}\right) \boldsymbol{n}_{\lambda}\right\rfloor \rrbracket, N_{a_{\lambda}\left(t+\frac{1}{4}\right)}^{S}(j)=N_{\boldsymbol{a}_{\lambda}\left(t-\frac{1}{2}\right)}^{S}(j)\right] \\
& \simeq 1-\nu_{S}\left(\left(0, \frac{3}{4} \boldsymbol{a}_{\lambda}\right)\right)^{\frac{1}{4} \boldsymbol{n}_{\lambda}} \\
& \simeq 1-\mathrm{e}^{-\nu_{S}\left(\left(\left(\frac{3}{4} a_{\lambda} / 4, \infty\right)\right) /\left[4 \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)\right]\right.},
\end{aligned}
$$

which tends to 1 as $\lambda \rightarrow 0$ due to $\left(H_{S}(\infty)\right)$. The probability of (c) (conditionally on (a)) also tends to 1 . Indeed, its value is nothing but

$$
\nu_{S}\left(\left(0, \frac{5}{12} a_{\lambda}\right)\right)^{2 k_{\lambda}+1} \simeq \mathrm{e}^{-2 \nu_{S}\left(\left(\frac{5}{12} a_{\lambda}, \infty\right)\right) / \nu_{S}\left(\left(\frac{3}{8} a_{\lambda}, \infty\right)\right)}
$$

which tends to 1 due to $\left(H_{S}(\infty)\right)$, since $\frac{5}{12}>\frac{3}{8}$. Finally, the probability of (d) (conditionally on (a)) also tends to 1 , since it equals

$$
1-\left(\nu_{S}\left(\left(0, \frac{1}{3} a_{\lambda}\right)\right)\right)^{2 k_{\lambda}+1} \simeq 1-\mathrm{e}^{-2 \nu_{S}\left(\left(\frac{1}{3} a_{\lambda}, \infty\right)\right) / \nu_{S}\left(\left(\frac{3}{8} a_{\lambda}, \infty\right)\right)},
$$

which tends to 1 due to $\left(H_{S}(\infty)\right)$, since $\frac{1}{3}<\frac{3}{8}$.
Step 3. - Let now $T>0$ be fixed. Set $K=\lfloor 4 T\rfloor$. For $a \in \mathbb{R}$, we set

$$
\widetilde{\Omega}_{a, T}^{\lambda}=\Omega_{a, 0}^{\lambda} \cap \bigcap_{k=2}^{K} \Omega_{a+(k-1), \frac{1}{4} k}^{\lambda}
$$

Then it is clear from steps 1 and 2 (observe that $\left(\frac{1}{4} K+\frac{1}{4} \geq T\right)$ ) that
(i) on $\widetilde{\Omega}_{a, T}^{\lambda}$, for all $t \in[0, T]$ there is $i \in \llbracket\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor, \llbracket\left\lfloor(a+K) \boldsymbol{n}_{\lambda}-1\right\rfloor \rrbracket$ such that $\eta_{a_{\lambda} t}^{\lambda}(i)=0$;
(ii) $p_{\lambda}=\operatorname{Pr}\left[\widetilde{\Omega}_{a, T}^{\lambda}\right]$ does not depend on $a$ and $p:=\liminf _{\lambda \rightarrow 0} p_{\lambda} \geq q^{K-1}>0$;
(iii) $\widetilde{\Omega}_{a, T}^{\lambda}$ depends only on $\left(N_{a_{\lambda} t}^{S}(i), N_{a_{\lambda} t}^{M, \lambda}(i)\right)_{t \in[0, T+1], i \in \llbracket\left\lfloor a n_{\lambda}\right\rfloor,\left\lfloor(a+K) n_{\lambda}\right\rfloor-1 \rrbracket}$.

Step 4. - We deduce that for all $a \in \mathbb{Z}$, conditionally on $\Omega_{a, T}^{\lambda}$, clusters on the left of $\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor-1$ are never connected (during $\left[0, \boldsymbol{a}_{\lambda} T\right]$ ) to clusters on the right of $\left\lfloor(a+K) \boldsymbol{n}_{\lambda}\right\rfloor$. Thus on $\Omega_{a, T}^{\lambda}$, fires starting on the left of $\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor-1$ do not affect the zone $\left\lfloor\left\lfloor(a+K) \boldsymbol{n}_{\lambda}\right\rfloor, \infty\right) \cap \mathbb{Z}$ and fires starting on the right of $\left\lfloor(a+K) \boldsymbol{n}_{\lambda}\right\rfloor$ do not affect the zone $\left(-\infty,\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor-1\right] \cap \mathbb{Z}$.

We deduce that for $A \geq 2 K$, the $\mathrm{FF}_{A}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process and the $\mathrm{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process coincide on $I_{A / 2}^{\lambda}$ during $\left[0, \boldsymbol{a}_{\lambda} T\right]$ as soon as there are $a_{1} \in\left[-A,-\frac{1}{2} A-K\right]$ and $a_{2} \in\left[\frac{1}{2} A, A-K\right]$ with $\Omega_{a_{1}, T}^{\lambda} \cap \Omega_{a_{2}, T}^{\lambda}$ realized. Furthermore, $\Omega_{a, T}^{\lambda}$ is independent of $\Omega_{b, T}^{\lambda}$ for all $a, b \in \mathbb{Z}$ with $|a-b|>K$. Thus we can bound the probabilities of the statement from below, for $A \geq 2 K$ and $\lambda>0$ small enough (so that $\operatorname{Pr}\left[\Omega_{a, T}^{\lambda}\right] \geq \frac{1}{2} p$ ), by

$$
\begin{aligned}
1-\operatorname{Pr} & {\left[\bigcap_{\ell=1}^{\lfloor A /(2 K)\rfloor}\left(\Omega_{\lfloor-A\rfloor+\ell K, T}^{\lambda}\right)^{c}\right]-\operatorname{Pr}\left[\bigcap_{\ell=1}^{\lfloor A /(2 K)\rfloor}\left(\Omega_{\lfloor A / 2\rfloor+\ell K, T}^{\lambda}\right)^{c}\right] } \\
& \geq 1-2\left(1-\frac{1}{2} p\right)^{\lfloor A /(2 K)\rfloor} \geq 1-2\left(1-\frac{1}{2} p\right)^{A /(2 K)-1} .
\end{aligned}
$$

This concludes the proof: choose $C_{T}=2 /\left(1-\frac{1}{2} p\right)>0(p$ depends only on $T)$ and $\alpha_{T}=-\log \left(1-\frac{1}{2} p\right) /(2 K)>0$.

When $\beta=B S$, the proof is similar, but consequently simpler.
Proof when $\beta=B S$. - Recall that $\boldsymbol{a}_{\lambda}=T_{S}$ and consider the true $\operatorname{FF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$ process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. For $a \in \mathbb{R}$, let

$$
J_{a}^{\lambda}=\left[\left[\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor,\left\lfloor(a+1) \boldsymbol{n}_{\lambda}\right\rfloor-1\right]\right] .
$$

Step 1. - We show here that for all $a \in \mathbb{R}$, there exists an event $\Omega_{a, 0}^{\lambda}$, depending only on $\left(N_{s}^{S}(i), N_{s}^{M, \lambda}(i)\right)_{i \in J_{a}^{\lambda}, s \in\left[0, \frac{3}{4} a_{\lambda}\right]}$ such that
(i) on $\Omega_{a, 0}^{\lambda}$, a.s., there is $i \in J_{a}^{\lambda}$ such that $\eta_{a_{\lambda} s}^{\lambda}(i)=0$ for all $s \in\left[0, \frac{3}{4}\right]$;
(ii) $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\Omega_{a, 0}^{\lambda}\right]=1$.

This is done as in the case where $\beta=\infty$. Consider simply

$$
\Omega_{a, 0}^{\lambda}=\left\{\exists i \in J_{a}^{\lambda}, N_{\frac{3}{4} a_{\lambda}}^{S}(i)=0\right\} .
$$

Clearly, (i) is satisfied. To check (ii), recall that $\left|J_{a}^{\lambda}\right|=\boldsymbol{n}_{\lambda} \rightarrow \infty$, whence

$$
\operatorname{Pr}\left[\Omega_{a, 0}^{\lambda}\right]=1-\nu_{S}\left(\left(0, \frac{3}{4} T_{S}\right)\right)^{n_{\lambda}} \longrightarrow 1,
$$

because $\nu_{S}\left(\left(0, \frac{3}{4} T_{S}\right)\right)<1\left(\right.$ recall that supp $\left.\nu_{S}=\left[0, T_{S}\right]\right)$.

Step 2. - We now check that for all $a \in \mathbb{R}$, all $t \geq \frac{1}{2}$, there exists an event $\Omega_{a, t}^{\lambda}$, depending only on $\left(N_{s}^{S}(i), N_{s}^{M, \lambda}(i)\right)_{i \in J_{a}^{\lambda}, s \in\left[\left(t-\frac{1}{4}\right) a_{\lambda},\left(t+\frac{1}{4}\right) a_{\lambda}\right]}$ such that
(i) on $\Omega_{a, t}^{\lambda}$, a.s., there is $i \in J_{a}^{\lambda}$ such that $\eta_{a_{\lambda} s}^{\lambda}(i)=0$ for all $s \in\left[t, t+\frac{1}{4}\right]$;
(ii) $q_{\lambda}:=\operatorname{Pr}\left[\Omega_{a, t}^{\lambda}\right]$ does not depend on $t, a$ and $q:=\liminf _{\lambda \rightarrow 0} q_{\lambda}>0$.

This is much easier than in the case where $\beta=\infty$ : simply set

$$
\Omega_{a, t}^{\lambda}=\left\{\exists i_{0} \in J_{a}^{\lambda}, N_{\boldsymbol{a}_{\lambda}\left(t+\frac{1}{4}\right)}^{S}\left(i_{0}\right)=N_{\boldsymbol{a}_{\lambda}\left(t-\frac{1}{4}\right)}^{S}\left(i_{0}\right), N_{\boldsymbol{a}_{\lambda} t}^{M, \lambda}\left(i_{0}\right)>N_{\boldsymbol{a}_{\lambda}\left(t-\frac{1}{4}\right)}^{M, \lambda}\left(i_{0}\right)\right\} .
$$

Point (i) is obviously checked since no seed fall on $i_{0}$ during $\left[\boldsymbol{a}_{\lambda}\left(t-\frac{1}{4}\right), \boldsymbol{a}_{\lambda}\left(t+\frac{1}{4}\right)\right]$ and a match falls on $i_{0}$ during $\left[\boldsymbol{a}_{\lambda}\left(t-\frac{1}{4}\right), \boldsymbol{a}_{\lambda} t\right]$. Next, $\operatorname{Pr}\left(\Omega_{a, t}^{\lambda}\right)=1-r_{\lambda}^{\left|J_{a}^{\lambda}\right|}$, where (for any $i \in \mathbb{Z}$, any $t \geq \frac{1}{4}$ )

$$
\begin{aligned}
r_{\lambda}: & =\operatorname{Pr}\left[N_{\boldsymbol{a}_{\lambda}\left(t+\frac{1}{4}\right)}^{S}\left(i_{0}\right)>N_{\boldsymbol{a}_{\lambda}\left(t-\frac{1}{4}\right)}^{S}\left(i_{0}\right) \text { or } N_{\boldsymbol{a}_{\lambda} t}^{M, \lambda}\left(i_{0}\right)=N_{\boldsymbol{a}_{\lambda}\left(t-\frac{1}{4}\right)}^{M, \lambda}\left(i_{0}\right)\right] \\
& =\operatorname{Pr}\left[N_{\frac{1}{2} a_{\lambda}}^{S}(i)>0 \text { or } N_{\frac{1}{4} a_{\lambda}}^{M}(i)=0\right] \\
& =\nu_{S}\left(\left[0, \frac{1}{2} T_{S}\right]\right)+\nu_{M}^{\lambda}\left(\left(\frac{1}{4} T_{S}, \infty\right)\right)-\nu_{S}\left(\left[0, \frac{1}{2} T_{S}\right]\right) \nu_{M}^{\lambda}\left(\left(\frac{1}{4} T_{S}, \infty\right)\right) .
\end{aligned}
$$

Due to $\left(H_{M}\right)$,

$$
\nu_{M}^{\lambda}\left(\left(\frac{1}{4} T_{S}, \infty\right)\right)=1-\lambda \int_{0}^{\frac{1}{4} T_{S}} \mu_{M}^{1}(\lambda t, \infty) \mathrm{d} t=1-\lambda \frac{1}{4} T_{S}(1+\varepsilon(\lambda))
$$

for some function $\varepsilon$ such that $\lim _{\lambda \rightarrow 0} \varepsilon(\lambda)=0$. Setting $\alpha=\nu_{S}\left(\left[0, \frac{1}{2} T_{S}\right]\right) \in(0,1)$, we deduce that

$$
\begin{aligned}
r_{\lambda} & =\alpha+1-\frac{1}{4} \lambda T_{S}(1+\varepsilon(\lambda))-\alpha\left(1-\frac{1}{4} \lambda T_{S}(1+\varepsilon(\lambda))\right) \\
& =1-\frac{1}{4} \lambda(1-\alpha) T_{S}(1+\varepsilon(\lambda)) .
\end{aligned}
$$

Recalling that $\left|J_{a}^{\lambda}\right| \simeq \boldsymbol{n}_{\lambda} \simeq 1 /\left(\lambda T_{S}\right)$, we finally conclude that

$$
\operatorname{Pr}\left(\Omega_{a, t}^{\lambda}\right) \simeq 1-r_{\lambda}^{1 /\left(\lambda T_{S}\right)} \rightarrow 1-\mathrm{e}^{-\frac{1}{4}(1-\alpha)}=: q>0 .
$$

Steps 3 and 4 are exactly the same as when $\beta=\infty$.
3.8. Localization of the results when $\beta \in\{\infty, B S\}$

We recall that $\boldsymbol{a}_{\lambda}, \boldsymbol{n}_{\lambda}$ are defined in (2.2.1) and (2.2.2). For $A>0$ and $i \in \mathbb{Z}$, we set as usual

$$
A_{\lambda}=\left\lfloor A \boldsymbol{n}_{\lambda}\right\rfloor, \quad I_{A}^{\lambda}=\llbracket-A_{\lambda}, A_{\lambda} \rrbracket, \quad i_{\lambda}=\left[i / \boldsymbol{n}_{\lambda},(i+1) / \boldsymbol{n}_{\lambda}\right) .
$$

In the next sections, we will prove the following localized version of Theorems 2.3.3 and 2.4.4, separating the cases $\beta=\infty$ and $\beta=B S$.

Proposition 3.8.1. - Let $\beta \in\{\infty, B S\}$. Assume $\left(H_{M}\right)$ and $\left(H_{S}(\beta)\right)$. Let $A>0$ be fixed. Consider, for each $\lambda \in(0,1]$, the process $\left(Z_{t}^{\lambda, A}(x), D_{t}^{\lambda, A}(x)\right)_{t \geq 0, x \in[-A, A]}$ associated with the $\mathrm{FF}_{A}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process and the $\operatorname{LFF}_{A}(\beta)$-process

$$
\left(Z_{t}^{A}(x), D_{t}^{A}(x), H_{t}^{A}(x)\right)_{t \geq 0, x \in[-A, A]} .
$$

(a) For any $T>0$, any $\left\{x_{1}, \ldots, x_{p}\right\} \subset[-A, A],\left(Z_{t}^{\lambda, A}\left(x_{i}\right), D_{t}^{\lambda, A}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p}$ goes in law to

$$
\left(Z_{t}^{A}\left(x_{i}\right), D_{t}^{A}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p},
$$

in $\mathbb{D}([0, T], \mathbb{R} \times \mathcal{I} \cup\{\varnothing\})^{p}$, as $\lambda$ tends to 0 . Here $\mathbb{D}([0, \infty), \mathbb{R} \times \mathcal{I} \cup\{\varnothing\})$ is endowed with the distance $\boldsymbol{d}_{T}$.
(b) For any $\left\{\left(t_{1}, x_{1}\right), \ldots,\left(t_{p}, x_{p}\right)\right\} \subset[0, \infty) \times[-A, A]$ (assume also that $t_{k} \neq 1$ for $k=1, \ldots, p$ if $\beta=\infty),\left(Z_{t_{i}}^{\lambda, A}\left(x_{i}\right), D_{t_{i}}^{\lambda, A}\left(x_{i}\right)\right)_{i=1, \ldots, p}$ goes in law to

$$
\left(Z_{t_{i}}^{A}\left(x_{i}\right), D_{t_{i}}^{A}\left(x_{i}\right)\right)_{i=1, \ldots, p}
$$

in $(\mathbb{R} \times \mathcal{I} \cup\{\varnothing\})^{p}$. Here $\mathcal{I} \cup\{\varnothing\}$ is endowed with $\boldsymbol{\delta}$.
(c)-(i) Assume first that $\beta=\infty$. For all $t>0$,

$$
\left(\frac{\psi_{S}\left(1-1 /\left|C_{A}\left(\eta_{a_{\lambda} t}^{\lambda, A}, 0\right)\right|\right)}{\boldsymbol{a}_{\lambda}} \mathbb{1}_{\left\{\left|C_{A}\left(\eta_{a_{\lambda} t}^{\lambda, A}, 0\right)\right| \geq 1\right\}}\right) \wedge 1
$$

goes in law to $Z_{t}^{A}(0)$ as $\lambda \rightarrow 0$.
(c)-(ii) Assume next that $\beta=B S$. For any $t \geq 0$, any $k \in \mathbb{N}$, there holds

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|C_{A}\left(\eta_{T_{S} t}^{\lambda, A}, 0\right)\right|=k\right]=\mathbb{E}\left[q_{k}\left(Z_{t}^{A}(0)\right)\right]
$$

where $q_{k}(z)$ was defined, for $k \geq 0$ and $z \in[0,1]$, in (2.4.2).

Assuming for a moment that this proposition holds true, we conclude the proofs of Theorems 2.3.3 and 2.4.4.

Proof of Theorem 2.3.3. - Let us first prove (a). Consider a continuous bounded functional $\Psi: \mathbb{D}([0, T], \mathbb{R} \times \mathcal{I} \cup\{\varnothing\})^{p} \mapsto \mathbb{R}$. We have to prove that $\lim _{\lambda \rightarrow 0} G_{\lambda}(\Psi)=0$, where

$$
\begin{aligned}
& G_{\lambda}(\Psi)=\mathbb{E}\left[\Psi\left(\left(Z_{t}^{\lambda}\left(x_{i}\right), D_{t}^{\lambda}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p)}\right)\right. \\
&-\mathbb{E}\left[\Psi\left(\left(Z_{t}\left(x_{i}\right), D_{t}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p}\right)\right]
\end{aligned}
$$

Using now Propositions 3.6.4 and 3.7.2, we observe that for any $A>2 \max _{i=1, \ldots, p}\left|x_{i}\right|$, for all $\lambda \in(0,1]$ small enough,

$$
\begin{aligned}
&\left|G_{\lambda}(\Psi)\right| \leq 2\|\Psi\|_{\infty} \operatorname{Pr}\left[\left(Z_{t}^{\lambda, A}(x), D_{t}^{\lambda, A}(x)\right)_{t \in[0, T], x \in\left[-\frac{1}{2} A, \frac{1}{2} A\right]}\right. \\
&\left.\neq\left(Z_{t}^{\lambda}(x), D_{t}^{\lambda}(x)\right)_{t \in[0, T], x \in\left[-\frac{1}{2} A, \frac{1}{2} A\right]}\right] \\
&+2\|\Psi\|_{\infty} \operatorname{Pr}\left[\left(Z_{t}^{A}(x), D_{t}^{A}(x)\right)_{t \in[0, T], x \in\left[-\frac{1}{2} A, \frac{1}{2} A\right]}\right. \\
&\left.\neq\left(Z_{t}(x), D_{t}(x)\right)_{t \in[0, T], x \in\left[-\frac{1}{2} A, \frac{1}{2} A\right]}\right] \\
&+\mid \mathbb{E}\left[\Psi \left(\left(Z_{t}^{\lambda, A}\left(x_{i}\right), D_{t}^{\lambda, A}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p)]}\right.\right. \\
&-\mathbb{E}\left[\Psi \left(\left(Z_{t}^{A}\left(x_{i}\right), D_{t}^{A}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p)] \mid} \mid\right.\right. \\
& \leq 4\|\Psi\|_{\infty} C_{T} \mathrm{e}^{-\alpha_{T} A}+\mid \mathbb{E}\left[\Psi\left(\left(Z_{t}^{\lambda, A}\left(x_{i}\right), D_{t}^{\lambda, A}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p}\right)\right] \\
& \quad-\mathbb{E}\left[\Psi\left(\left(Z_{t}^{A}\left(x_{i}\right), D_{t}^{A}\left(x_{i}\right)\right)_{t \in[0, T], i=1, \ldots, p}\right)\right] \mid
\end{aligned}
$$

Thus Proposition 3.8.1 (a) implies that $\lim \sup _{\lambda \rightarrow 0}\left|G_{\lambda}(\Psi)\right| \leq 4\|\Psi\|_{\infty} C_{T} \mathrm{e}^{-\alpha_{T} A}$. We conclude by making $A$ tend to infinity.

Point (b) is checked similarly. The proof of (c) is also similar, since $D_{t}^{\lambda}(0)=$ $D_{t}^{\lambda, A}(0)$ implies that $C\left(\eta_{a_{\lambda} t}^{\lambda}, 0\right)=C_{A}\left(\eta_{a_{\lambda} t}^{\lambda, A}, 0\right)$.

Proof of Theorem 2.4.4. - It is deduced from Propositions 3.6.4, 3.7.2 and 3.8.1 exactly as Theorem 2.3.3.

### 3.9. Convergence proof when $\beta=B S$

The aim of this section is to prove Proposition 3.8.1 in the case where $\beta=B S$ and this will conclude the proof of Theorem 2.4.4. In the whole section, we thus assume $\left(H_{M}\right)$ and $\left(H_{S}(B S)\right)$. The parameters $A>0$ and $T>0$ are fixed and we omit the subscript/superscript $A$ in the whole proof.

We recall that $\boldsymbol{a}_{\lambda}, \boldsymbol{n}_{\lambda}$ and $\boldsymbol{m}_{\lambda}$ are defined in (2.2.1), (2.2.2) and (2.2.4). For $A>0$ and $i \in \mathbb{Z}$, we set as usual

$$
A_{\lambda}=\left\lfloor A \boldsymbol{n}_{\lambda}\right\rfloor, \quad I_{A}^{\lambda}=\llbracket-A_{\lambda}, A_{\lambda} \rrbracket, \quad i_{\lambda}=\left[i / \boldsymbol{n}_{\lambda},(i+1) / \boldsymbol{n}_{\lambda}\right) .
$$

For $[a, b]$ an interval of $[-A, A]$ and $\lambda \in(0,1)$, we introduce, assuming $-A<a<b<A$,

$$
\left\{\begin{array}{l}
{[a, b]_{\lambda}=\llbracket\left\lfloor\boldsymbol{n}_{\lambda} a+\boldsymbol{m}_{\lambda}\right\rfloor+1,\left\lfloor\boldsymbol{n}_{\lambda} b-\boldsymbol{m}_{\lambda}\right\rfloor-1 \rrbracket \subset \mathbb{Z}}  \tag{3.9.1}\\
{[-A, b]_{\lambda}=\llbracket-A_{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} b-\boldsymbol{m}_{\lambda}\right\rfloor-1 \rrbracket \subset \mathbb{Z}} \\
{[a, A]_{\lambda}=\llbracket\left\lfloor\boldsymbol{n}_{\lambda} a+\boldsymbol{m}_{\lambda}\right\rfloor+1, A_{\lambda} \rrbracket \subset \mathbb{Z}}
\end{array}\right.
$$

For $x \in(-A, A)$ and $\lambda \in(0,1)$, we introduce

$$
\begin{equation*}
x_{\lambda}=\left[\left[\left\lfloor\boldsymbol{n}_{\lambda} x-\boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\boldsymbol{n}_{\lambda} x+\boldsymbol{m}_{\lambda}\right\rfloor\right]\right] \subset \mathbb{Z} \tag{3.9.2}
\end{equation*}
$$

3.9.1. Height of the barriers. - We need the following lemma. It describes the time needed for a destroyed (microscopic) cluster to be regenerated. Below, we assume that the zone around 0 is completely vacant at time $T_{S} t_{0}$. Then we consider the situation where a match falls on the site 0 at some time $T_{S} t_{1} \in\left(T_{S} t_{0}, T_{S}\left(t_{0}+1\right)\right)$ and we compute the law of $\Theta_{t_{0}, t_{1}}$, which is the delay needed for the destroyed cluster to be fully regenerated (divided by $T_{S}$ ).

Lemma 3.9.1. - Consider a family of i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes $\left(N_{t}^{S}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. Let $0 \leq t_{0}<t_{1}<t_{0}+1$ be fixed. Put

$$
\begin{aligned}
& \zeta_{t_{0}, t}(i)=\min \left(N_{T_{S}\left(t_{0}+t\right)}^{S}(i)-N_{T_{S} t_{0}}^{S}(i), 1\right), \\
& \zeta_{t_{1}, t}(i)=\min \left(N_{T_{S}\left(t_{1}+t\right)}^{S}(i)-N_{T_{S} t_{1}}^{S}(i), 1\right)
\end{aligned}
$$

for all $t>0$ and $i \in \mathbb{Z}$. Define

$$
\Theta_{t_{0}, t_{1}}=\inf \left\{t>0: \forall i \in C\left(\zeta_{t_{0}, t_{1}-t_{0}}, 0\right), \zeta_{t_{1}, t}(i)=1\right\} \in[0,1] .
$$

The the law of $\Theta_{t_{0}, t_{1}}$ is $\theta_{t_{1}-t_{0}}$, recall Definition 2.4.1.
Proof. - We can assume that $t_{0}=0$ by stationarity. We put $u=t_{1}=t_{1}-t_{0}$ and write, for $h \in[0,1]$,

$$
\begin{aligned}
\operatorname{Pr}\left[\Theta_{t_{0}, t_{1}} \leq h\right]= & \operatorname{Pr}\left[N_{T_{S} u}^{S}(0)=0\right] \\
& +\sum_{k \geq 1} \sum_{j=0}^{k-1} \operatorname{Pr}\left[N_{T_{S} u}^{S}(j-k)=\right. \\
& N_{T_{S} u}^{S}(j+1)=0, \forall i \in \llbracket j-k+1, j \rrbracket, \\
& \left.N_{T_{S} u}^{S}(i)>0, N_{T_{S}(u+h)}^{S}(i)>N_{T_{S} u}^{S}(i)\right]
\end{aligned}
$$

This yields, since $g_{S}(u, h)=\operatorname{Pr}\left[N_{T_{S} u}^{S}>0, N_{T_{S}(u+h)}^{S}>N_{T_{S} u}^{S}\right]$,

$$
\begin{aligned}
\operatorname{Pr}\left[\Theta_{t_{0}, t_{1}} \leq h\right] & =\nu_{S}\left(\left[T_{S} u, T_{S}\right]\right)+\sum_{k \geq 1} k\left[\nu_{S}\left(\left[T_{S} u, T_{S}\right]\right)\right]^{2} \cdot\left[g_{S}(u, h)\right]^{k} \\
& =\nu_{S}\left(\left[T_{S} u, T_{S}\right]\right)+\frac{\left[\nu_{S}\left(\left[T_{S} u, T_{S}\right]\right)\right]^{2}}{\left[1-g_{S}(u, h)\right]^{2}} g_{S}(u, h)=\theta_{u}([0, h]),
\end{aligned}
$$

recall Definition 2.4.1.
3.9.2. Persistent effect of microscopic fires. - Here we study the effect of microscopic fires. First, they produce a barrier, and then, if there are alternatively macroscopic fires on the left and right, they still have an effect. This phenomenon is illustrated on Figure 8 next page in the case of the limit process.

We say that $\mathcal{R}=\left(\varepsilon ; t_{0}, t_{1}, \ldots, t_{K} ; s\right)$ satisfies (PP) (like ping-pong) if
(i) $K \geq 2, \varepsilon \in\{-1,1\}$;
(ii) $0<t_{0}<t_{1}<\cdots<t_{K}<s<t_{K}+1$;
(iii) for all $k=0, \ldots, K-1, t_{k+1}-t_{k}<1$;
(iv) $t_{2}-t_{0}>1$ and for all $k=2, \ldots, K-2, t_{k+2}-t_{k}>1$.

$\qquad$

Figure 8. Persistent effect of a microscopic fire. Here $\mathcal{R}=\left(1 ; t_{0}, t_{1}, t_{2}, t_{3}, t_{4} ; s\right)$.

We set $\varepsilon_{k}=(-1)^{k} \varepsilon$ for $k \geq 0$.
Consider a family of i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes $\left(N_{t}^{S}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$.
We introduce, for each $\lambda \in(0,1)$, the process $\left(\zeta_{t}^{\lambda, \mathcal{R}}(i)\right)_{t \geq t_{0}, i \in \llbracket-m_{\lambda}, m_{\lambda} \rrbracket}$ defined as follows:
$\triangleright$ for all $t \in\left[t_{0}, t_{1}\right)$, all $i \in \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket, \zeta_{t}^{\lambda, \mathcal{R}}(i)=\min \left(N_{T_{S} t}^{S}(i)-N_{T_{S} t_{0}}^{S}(i), 1\right)$;
$\triangleright$ for all $i \in \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket, \zeta_{t_{1}}^{\lambda, \mathcal{R}}(i)=\zeta_{t_{1}-}^{\lambda, \mathcal{R}}(i) \mathbb{1}_{\left\{i \notin C\left(\zeta_{t_{1}-}^{\lambda, \mathcal{R}}, 0\right)\right\}} ;$
$\triangleright$ for $k=1, \ldots, K-1$,
$\left.{ }^{*}\right)$ for all $t \in\left(t_{k}, t_{k+1}\right), i \in \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket$,

$$
\zeta_{t}^{\lambda, \mathcal{R}}(i)=\min \left(\zeta_{t_{k}}^{\lambda, \mathcal{R}}(i)+N_{T_{S} t}^{S}(i)-N_{T_{S} t_{k}}^{S}(i), 1\right)
$$

(*) for all $i \in \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket$,

$$
\zeta_{t_{k+1}}^{\lambda, \mathcal{R}}(i)=\zeta_{t_{k+1}-}^{\lambda, \mathcal{R}}(i) \mathbb{1}_{i \notin C\left(\zeta_{t_{k+1}-}^{\lambda, \mathcal{R}}, \epsilon_{k} m_{\lambda}\right)}
$$

$\triangleright$ for all $t \in\left(t_{K}, \infty\right), i \in \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket$,

$$
\zeta_{t}^{\lambda, \mathcal{R}}(i)=\min \left(\zeta_{t_{K}}^{\lambda, \mathcal{R}}(i)+N_{T_{S} t}^{S}(i)-N_{T_{S} t_{K}}^{S}(i), 1\right)
$$

Roughly, we start at time $T_{S} t_{0}$ with an empty configuration and seeds fall according to $\left(N_{t}^{S}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. At time $T_{S} t_{1}$, there is a (microscopic) fire at 0 . Then alternatively on the left and right, far away from 0 (at $-\boldsymbol{m}_{\lambda}$ or at $\boldsymbol{m}_{\lambda}$ ), there is a (macroscopic) fire at time $T_{S} t_{k}$.

Consider the event
$\Omega_{\mathcal{R}}^{S}(\lambda)=\left\{\exists-\boldsymbol{m}_{\lambda}<i_{1}<i_{2}<i_{3}<\boldsymbol{m}_{\lambda}: \zeta_{s}^{\lambda, \mathcal{R}}\left(i_{1}\right)=\zeta_{s}^{\lambda, \mathcal{R}}\left(i_{3}\right)=0, \zeta_{s}^{\lambda, \mathcal{R}}\left(i_{2}\right)=1\right\}$.

Lemma 3.9.2. - Let $\mathcal{R}=\left(\varepsilon ; t_{0}, t_{1}, \ldots, t_{K} ; s\right)$ satisfy (PP). Consider $\Theta_{t_{0}, t_{1}}$ defined in Lemma 3.9.1 and $\left(\zeta_{t}^{\lambda, \mathcal{R}}(i)\right)_{t \geq t_{0}, i \in \llbracket-m_{\lambda}, m_{\lambda} \rrbracket}$ defined above. There holds

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\Omega_{\mathcal{R}}^{S}(\lambda) \mid \Theta_{t_{0}, t_{1}}>t_{2}-t_{1}\right)=1
$$

Proof. - We assume that $\varepsilon=1$ and that $K$ is even for simplicity. Fix $\alpha=1 / K$.
First fire. - We put $C=C\left(\zeta_{t_{1}-}^{\lambda, \mathcal{R}}, 0\right)$. Since $t_{1}-t_{0}<1$ (so that each site is vacant with probability $\nu_{S}\left(\left(T_{S}\left(t_{1}-t_{0}\right), T_{S}\right)\right)>0$ at time $\left.t_{1}\right)$, the probability that $C \subset \llbracket-\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$ clearly tends to 1 . Thus the match falling at time $t_{1}$ at 0 destroys nothing outside $\llbracket-\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$ (with probability tending to 1).

Second fire. - Since $t_{2}-t_{0}>1$ (so that $T_{S}\left(t_{2}-t_{0}\right)>T_{S}$ ), at least one seed has fallen, during $\left[t_{0}, t_{2}\right)$ on each site of $\llbracket\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor+1, \boldsymbol{m}_{\lambda} \rrbracket$. Thus the fire at time $t_{2}$ destroys completely this zone, but does not affect $\llbracket-\boldsymbol{m}_{\lambda},-\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor-1 \rrbracket$, because $t_{2}<t_{1}+\Theta_{t_{0}, t_{1}}$ and because by definition of $\Theta_{t_{0}, t_{1}}$, there is an empty site in $C \subset \llbracket-\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$ during $\left[t_{1}, t_{1}+\Theta_{t_{0}, t_{1}}\right]$.

Third fire. - Since $t_{3}-t_{2}<1$, the probability that there is a vacant site in $\llbracket\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor+1,\left\lfloor 2 \alpha \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$ at time $t_{3}$ tends to 1 as $\lambda \rightarrow 0$.

Next, all the sites of $\llbracket-\boldsymbol{m}_{\lambda},-\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor-1 \rrbracket$ are occupied at time $t_{3}$ - (because they have not been affected by a fire and because $t_{3}-t_{0}>t_{2}-t_{0}>1$ ). Thus the fire at time $t_{3}$ destroys the zone $\llbracket-\boldsymbol{m}_{\lambda},-\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor-1 \rrbracket$ and does not affect the zone $\llbracket\left\lfloor 2 \alpha \boldsymbol{m}_{\lambda}\right\rfloor, \boldsymbol{m}_{\lambda} \rrbracket$.

Fourth fire. - Since $t_{4}-t_{3}<1$, the probability that there is (at least) a vacant site in $\llbracket-\left\lfloor 2 \alpha \boldsymbol{m}_{\lambda}\right\rfloor,-\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor-1 \rrbracket$ at time $t_{4}$ tends to 1 as $\lambda \rightarrow 0$.

Next, all the sites of $\llbracket\left\lfloor 2 \alpha \boldsymbol{m}_{\lambda}\right\rfloor, \boldsymbol{m}_{\lambda} \rrbracket$ are occupied at time $t_{4}$ - (because they have not been affected by a fire during $\left(t_{2}, t_{4}\right)$ with $t_{4}-t_{2}>1$ ). Thus the fire at time $t_{4}$ destroys the zone $\llbracket\left\lfloor 2 \alpha \boldsymbol{m}_{\lambda}\right\rfloor, \boldsymbol{m}_{\lambda} \rrbracket$ and does not affect the zone $\llbracket-\boldsymbol{m}_{\lambda},-\left\lfloor 2 \alpha \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$.

Last fire and conclusion. - Iterating the procedure, we see that with a probability tending to 1 as $\lambda \rightarrow 0$, the fire at time $t_{K}$ destroys the zone

$$
\left[\left[\left\lfloor\left(\frac{1}{2} K \alpha\right) \boldsymbol{m}_{\lambda}\right\rfloor, \boldsymbol{m}_{\lambda}\right]\right]=\left[\left[\left\lfloor\frac{1}{2} \boldsymbol{m}_{\lambda}\right\rfloor, \boldsymbol{m}_{\lambda}\right]\right] .
$$

Then one easily concludes: since $0<s-t_{K}<1$, the probability that there is at least one site in $\llbracket\left\lfloor\frac{1}{2} \boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\frac{2}{3} \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$ with no seed falling during $\left[t_{K}, s\right]$ tends to 1 , the probability that there is at least one site in $\llbracket\left\lfloor\frac{2}{3} \boldsymbol{m}_{\lambda}\right\rfloor+1,\left\lfloor\frac{5}{6} \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$ with at least one seed falling during $\left[t_{K}, s\right]$ tends to 1 , and the probability that there is at least one site in $\llbracket\left\lfloor\frac{5}{6} \boldsymbol{m}_{\lambda}\right\rfloor+1, \boldsymbol{m}_{\lambda} \rrbracket$ with no seed falling during $\left[t_{K}, s\right]$ tends to 1 .
3.9.3. The coupling. - We are going to construct a coupling between the $\mathrm{FF}_{A}\left(\mu_{S}, \mu_{M}^{\lambda}\right.$ )-process (on the time interval $\left[0, T_{S} T\right]$ ) and the $\mathrm{LFF}_{A}(B S)$-process (on $[0, T]$ ).

First, we couple a family of i.i.d. $\operatorname{SR}\left(\mu_{M}^{\lambda}\right)$-processes $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ with a Poisson measure $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)$ on $[0, T] \times[-A, A]$ with intensity measure $\mathrm{d} t \mathrm{~d} x$ as in Proposition 3.2.1.

We call $n:=\pi_{M}([0, T] \times[-A, A])$ and we consider the marks $\left(T_{q}, X_{q}\right)_{q=1, \ldots, n}$ of $\pi_{M}$ ordered in such a way that $0<T_{1}<\cdots<T_{n}<T$.

Next, we introduce some i.i.d. families of i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes $\left(N_{t}^{S, q}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$, for $q=0,1, \ldots$, independent of $\pi_{M}$ and $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$.

Then we build a family of i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes, independent of $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ and of $\pi_{M}$, as follows.
$\triangleright$ For $q \in\{1, \ldots, n\}$, for all $i \in\left(X_{q}\right)_{\lambda}$ (recall that $\left(X_{q}\right)_{\lambda}=\llbracket\left\lfloor\boldsymbol{n}_{\lambda} X_{q}-\boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\boldsymbol{n}_{\lambda} X_{q}+\right.$ $\left.\left.m_{\lambda}\right\rfloor \rrbracket\right)$ set

$$
\left(N_{t}^{S, \lambda}(i)\right)_{t \geq 0}=\left(N_{t}^{S, q}\left(i-\left\lfloor\boldsymbol{n}_{\lambda} X_{q}\right\rfloor\right)\right)_{t \geq 0} .
$$

(We have a problem if $i$ belongs to $\left(X_{q}\right)_{\lambda} \cap\left(X_{r}\right)_{\lambda}$ for some $q<r$. Then set e.g. $\left(N_{t}^{S, \lambda}(i)\right)_{t \geq 0}=\left(N_{t}^{S, q}\left(i-\left\lfloor\boldsymbol{n}_{\lambda} X_{q}\right\rfloor\right)\right)_{t \geq 0}$. This will occur with a very small probability, so that this choice is not important).
$\triangleright$ For all other $i \in \mathbb{Z}$ set

$$
\left(N_{t}^{S, \lambda}(i)\right)_{t \geq 0}=\left(N_{t}^{S, 0}(i)\right)_{t \geq 0}
$$

The $\mathrm{FF}_{A}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in I_{A}^{\lambda}}$ is built upon the seed processes $\left(N_{t}^{S, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ and match processes $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$.

The advantage of the previous construction is the following. When a match falls at some $X_{q}$ for the $\operatorname{LFF}_{A}(B S)$-process, it will fall at $\left\lfloor\boldsymbol{n}_{\lambda} X_{q}\right\rfloor$ in the discrete process, and thus if it is microscopic, it will involve the same seed processes for all values of $\lambda$.

It also considerably simplifies the dependence/independence considerations.
Finally, we build the $\mathrm{LFF}_{A}(B S)$-process. We consider the Poisson measure $\pi_{M}$ previously introduced, and for all $0<t_{0}<t_{1}<t_{0}+1$, for all $q=1, \ldots, n$, we consider $\Theta_{t_{0}, t_{1}}^{q}$ defined from $\left(N_{t}^{S, q}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ as in Lemma 3.9.1. We define $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \in[0, T], x \in[-A, A]}$ as follows:

Algorithm 3.9.3. - Consider the marks $\left(T_{k}, X_{k}\right)_{k=1, \ldots, n}$ of $\pi_{M}$ in $[0, T] \times[-A, A]$, ordered chronologically and set $T_{0}=0$.

Step 0. - Put $Z_{0}(x)=H_{0}(x)=0$ and $D_{0}(x)=\{x\}$ for all $x \in[-A, A]$.
Assume that for some $k \in\{0, \ldots, n-1\},\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \in\left[0, T_{k}\right], x \in[-A, A]}$ has been built.

Step $k+1$. - For $t \in\left(T_{k}, T_{k+1}\right)$ and $x \in[-A, A]$, put

$$
Z_{t}(x)=\min \left(1, Z_{T_{k}}(x)+t-T_{k}\right), \quad H_{t}(x)=\max \left(0, H_{T_{k}}(x)-t+T_{k}\right),
$$

and then define $D_{t}(x)$ as in (3.6.1). Finally, build $\left(Z_{T_{k+1}}(x), D_{T_{k+1}}(x), H_{T_{k+1}}(x)\right)$ as follows.
(i) If $Z_{T_{k+1}-}\left(X_{k+1}\right)=1$, set $H_{T_{k+1}}(x)=H_{T_{k+1}-}(x)$ for all $x \in[-A, A]$ and consider $[a, b]:=D_{T_{k+1}-}\left(X_{k+1}\right)$. Set

$$
\begin{aligned}
& Z_{T_{k+1}}(x)= \begin{cases}0 & \text { for all } x \in(a, b), \\
Z_{T_{k+1}-}(x) & \text { for all } x \in[-A, A] \backslash[a, b] .\end{cases} \\
& Z_{T_{k+1}}(a)= \begin{cases}0 & \text { if } Z_{T_{k+1}-}(a)=1, \\
Z_{T_{k+1}-}(a) & \text { if } Z_{T_{k+1}-}(a)<1,\end{cases} \\
& Z_{T_{k+1}}(b)= \begin{cases}0 & \text { if } Z_{T_{k+1}-}(b)=1, \\
Z_{T_{k+1}-}(b) & \text { if } Z_{T_{k+1}-}(b)<1 .\end{cases}
\end{aligned}
$$

(ii) If $Z_{T_{k+1}-}\left(X_{k+1}\right)<1$, set

$$
\begin{aligned}
H_{T_{k+1}}\left(X_{k+1}\right) & =\Theta_{T_{k+1}-}^{k+1} Z_{T_{k+1}-}\left(X_{k+1}\right), T_{k+1} \\
Z_{T_{k+1}}\left(X_{k+1}\right) & =Z_{T_{k+1}-}\left(X_{k+1}\right)
\end{aligned}
$$

and for all $x \in[-A, A] \backslash\left\{X_{k+1}\right\}$,

$$
\left(Z_{T_{k+1}}(x), H_{T_{k+1}}(x)\right)=\left(Z_{T_{k+1}-}(x), H_{T_{k+1}-}(x)\right) .
$$

(iii) Using the values of $\left(Z_{T_{k+1}}(x), H_{T_{k+1}}(x)\right)_{x \in[-A, A]}$, compute $\left(D_{T_{k+1}}(x)\right)_{x \in[-A, A]}$ as in (3.6.1).

Lemma 3.9.4. - The process $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \in[0, T], x \in[-A, A]}$ built in Algorithm 3.9.3 is a $\operatorname{LFF}_{A}(B S)$-process.

Proof. - The only difference between Algorithms 3.6.3 and 3.9.3 is that in step $k+1$, point (ii), we use $\Theta_{T_{k+1}-Z_{T_{k+1}-}\left(X_{k+1}\right), T_{k+1}}^{k+1}$ instead of $F_{S}\left(Z_{T_{k+1}-}\left(X_{k+1}\right), V_{k+1}\right)$.

But due to Lemma 3.9.1 and Definition 2.4.1, these two variables have the same law $\theta_{Z_{T_{k+1}-}\left(X_{k+1}\right)}$ (conditionally on $T_{k+1}, X_{k+1}$ and $\left.\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \in\left[0, T_{k+1}\right), x \in[-A, A]}\right)$. Indeed, it suffices to use that in Algorithm 3.6.3, $V_{k+1}$ is independent of $Z_{T_{k+1}-}\left(X_{k+1}\right)$, while in Algorithm 3.9.3, the family $\left(N_{t}^{S, k+1}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ is independent of $\left(T_{k+1}, Z_{T_{k+1}-}\left(X_{k+1}\right)\right)$.

Finally, we observe that $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \in[0, T], x \in[-A, A]}$ depends only on $\pi_{M}$ and on $\left(\left(N_{t}^{S, q}(i)\right)_{t \in[0, T], i \in \mathbb{Z}}\right)_{q \geq 1}$. It is independent of $\left(N_{t}^{S, 0}(i)\right)_{t \in[0, T], i \in \mathbb{Z}}$.
3.9.4. A favorable event. - First, we know from Proposition 3.2.1 that

$$
\Omega_{A, T}^{M}(\lambda):=\left\{\forall t \in[0, T], \forall i \in I_{A}^{\lambda}, \Delta N_{T_{S} t}^{M, \lambda}(i) \neq 0 \text { iff } \pi_{M}\left(\{t\} \times i_{\lambda}\right) \neq 0\right\}
$$

satisfies

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\Omega_{A, T}^{M}(\lambda)\right]=1
$$

Next, we recall that the marks of $\pi_{M}$ are called $\left(T_{1}, X_{1}\right), \ldots,\left(T_{n}, X_{n}\right)$ and are ordered chronologically. We introduce $\mathcal{T}_{M}=\left\{0, T_{1}, \ldots, T_{n}\right\}, \mathcal{B}_{M}=\left\{X_{1}, \ldots, X_{n}\right\}$, as well as the set $\mathcal{C}_{M}$ of connected components of $[-A, A] \backslash \mathcal{B}_{M}$ (sometimes referred to as cells).

For $\alpha>0$, we consider the event

$$
\Omega_{M}(\alpha)=\left\{\min _{\substack{s, t \in \mathcal{T}_{M} \\ s \neq t}}|t-s| \geq \alpha, \min _{\substack{x, y \in \mathcal{B}_{M} \cup\{-A, A\} \\ x \neq y}}|x-y| \geq \alpha,\right\},
$$

which clearly satisfies $\lim _{\alpha \rightarrow 0} \operatorname{Pr}\left[\Omega_{M}(\alpha)\right]=1$. Observe that for any given $\alpha>0$, there is $\lambda_{\alpha}>0$ such that for all $\lambda \in\left(0, \lambda_{\alpha}\right)$, on $\Omega_{M}(\alpha)$,
$\triangleright$ for all $x, y \in \mathcal{B}_{M} \cup\{-A, A\}$ with $x \neq y, x_{\lambda} \cap y_{\lambda}=\varnothing$;
$\triangleright$ the family $\left\{c_{\lambda}, c \in \mathcal{C}_{M}\right\} \cup\left\{x_{\lambda}, x \in \mathcal{B}_{M}\right\}$ is a partition of $I_{A}^{\lambda}$ (recall (3.9.1) and (3.9.2)).

Indeed, it suffices that $\sup _{\left(0, \lambda_{\alpha}\right)}\left[\boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}\right]<\frac{1}{4} \alpha$.
Let $q \in\{1, \ldots, n\}$. We call $\mathcal{U}_{q}$ the set of all possible $\mathcal{R}=\left(\varepsilon, t_{0}, \ldots, t_{K} ; s\right)$ satisfying (PP) with $\varepsilon \in\{-1,1\}$, with $\left\{t_{0}, \ldots, t_{K}, s\right\} \subset \mathcal{T}_{M}$ and with $\Theta_{t_{0}, t_{1}}^{q}>t_{2}-t_{1}$. We introduce, for $q=1, \ldots, n$ and $\mathcal{R} \in \mathcal{U}_{q}$, the event $\Omega_{\mathcal{R}}^{S, q}(\lambda)$ defined as in subsection 3.9.2 with the $\operatorname{SR}\left(\mu_{S}\right)$-processes $\left(N_{t}^{S, q}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. Then we put

$$
\Omega_{1}^{S}(\lambda)=\bigcap_{q=1}^{n} \bigcap_{\mathcal{R} \in \mathcal{U}_{q}} \Omega_{\mathcal{R}}^{S, q}(\lambda)
$$

which satisfies $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\Omega_{1}^{S}(\lambda)\right)=1$ thanks to Lemma 3.9.2 (since for each $q$, $\left(N_{t}^{S, q}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ is independent of $\pi_{M}$ and since conditionally on $\pi_{M}$, the set $\mathcal{U}_{q}$ is finite).

We also consider the event $\Omega_{2}^{S}(\lambda)$ on which the following conditions hold: for all $t_{1}, t_{2} \in \mathcal{T}_{M}$ with $0<t_{2}-t_{1}<1$, for all $q=1, \ldots, n$, there are

$$
-\boldsymbol{m}_{\lambda}<i_{1}<i_{2}<-\frac{1}{2} \boldsymbol{m}_{\lambda}<i_{3}<0<i_{4}<\frac{1}{2} \boldsymbol{m}_{\lambda}<i_{5}<i_{6}<\boldsymbol{m}_{\lambda}
$$

such that
$\triangleright$ for $j=1,3,4,6, \quad N_{T_{S} t_{2}}^{S, q}\left(i_{j}\right)-N_{T_{S} t_{1}}^{S, q}\left(i_{j}\right)=0$;
$\triangleright$ for $j=2,5, \quad N_{T_{S} t_{2}}^{S, q}\left(i_{j}\right)-N_{T_{S} t_{1}}^{S, q}\left(i_{j}\right)>0$.
There holds $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\Omega_{2}^{S}(\lambda)\right)=1$. Indeed, it suffices to prove that almost surely, $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\Omega_{2}^{S}(\lambda) \mid \pi_{M}\right)=1$. Since there are a.s. finitely many possibilities for $q, t_{1}, t_{2}$ and since $\pi_{M}$ is independent of $\left(N_{t}^{S, q}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$, it suffices to work with a fixed $q \in\{1, \ldots, n\}$ and some fixed $0<t_{2}-t_{1}<1$.

Observe that for each $i, \operatorname{Pr}\left(N_{T_{S} t_{2}}^{S, q}(i)-N_{T_{S} t_{1}}^{S, q}(i)=0\right)=\nu_{S}\left(\left(T_{S}\left(t_{2}-t_{1}\right), T_{S}\right)\right)<1$ and $\operatorname{Pr}\left(N_{T_{S} t_{2}}^{S, q}(i)-N_{T_{S} t_{1}}^{S, q}(i)>0\right)=\nu_{S}\left(\left(0, T_{S}\left(t_{2}-t_{1}\right)\right)\right)<1$ by definition of $T_{S}$ and since $t_{2}-t_{1}<1$. Recall also that $\boldsymbol{m}_{\lambda}$ tends to infinity. Thus during $\left[T_{S} t_{1}, T_{S} t_{2}\right]$, the probability that a seed falls on each site of $\llbracket-\boldsymbol{m}_{\lambda}+1,-\left\lfloor\frac{1}{4} \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$ tends to 0 , the
probability that no seed at all falls on $\llbracket-\left\lfloor\frac{1}{4} \boldsymbol{m}_{\lambda}\right\rfloor+1,-\left\lfloor\frac{1}{2} \boldsymbol{m}_{\lambda}\right\rfloor-1 \rrbracket$ tends to 0 , the probability a seed falls on each site of $\llbracket-\left\lfloor\frac{1}{2} \boldsymbol{m}_{\lambda}\right\rfloor,-1 \rrbracket$ tends to 0 , etc.

We finally introduce the event

$$
\Omega(\alpha, \lambda)=\Omega_{A, T}^{M}(\lambda) \cap \Omega_{M}(\alpha) \cap \Omega_{1}^{S}(\lambda) \cap \Omega_{2}^{S}(\lambda)
$$

We observe that $\Omega(\alpha, \lambda)$ is independent of $\left(N_{t}^{S, 0}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ and that for any $\varepsilon>0$, choosing $\alpha>0$ small enough, $\operatorname{Pr}[\Omega(\alpha, \lambda)]>1-\varepsilon$ for all $\lambda>0$ small enough.
3.9.5. Heart of the proof. - We now handle the main part of the proof.

Consider the $\operatorname{LFF}_{A}(B S)$-process. Observe that by construction, we have, for $c \in \mathcal{C}_{M}$ and $x, y \in c, Z_{t}(x)=Z_{t}(y)$ for all $t \in[0, T]$, thus we can introduce $Z_{t}(c)$.

If $x \in \mathcal{B}_{M}$, it is at the boundary of two cells $c_{-}, c_{+} \in \mathcal{C}_{M}$ and then for all $t \in[0, T]$ we set

$$
Z_{t}\left(x_{-}\right)=Z_{t}\left(c_{-}\right) \quad \text { and } \quad Z_{t}\left(x_{+}\right)=Z_{t}\left(c_{+}\right)
$$

If $x \in(-A, A) \backslash \mathcal{B}_{M}$, we put $Z_{t}\left(x_{-}\right)=Z_{t}\left(x_{+}\right)=Z_{t}(x)$ for all $t \in[0, T]$.
For $x \in \mathcal{B}_{M}$ and $t \geq 0$ we set

$$
\widetilde{H}_{t}(x)=\max \left(H_{t}(x), 1-Z_{t}(x), 1-Z_{t}\left(x_{-}\right), 1-Z_{t}\left(x_{+}\right)\right) .
$$

Observe that $x$ is microscopic or acts like a barrier at time $t$ if and only if $\widetilde{H}_{t}(x)>0$.
Actually $Z_{t}(x)$ always equals either $Z_{t}\left(x_{-}\right)$or $Z_{t}\left(x_{+}\right)$and these can be distinct only at a point where has occurred a microscopic fire (that is if $x=X_{q}$ for some $q \in\{1, \ldots, n\}$, if $Z_{T_{q}-}\left(X_{q}\right)<1$ and if $\left.t>T_{q}\right)$.

For all $x \in(-A, A)$ and $t \in[0, T]$, we put

$$
\tau_{t}(x)=\sup \left\{s \leq t: Z_{s}\left(x_{+}\right)=Z_{s}\left(x_{-}\right)=Z_{s}(x)=0\right\} \in[0, t] \cap \mathcal{T}_{M}
$$

For $c \in \mathcal{C}_{M}$ and $t \in[0, T]$, we clearly have $\tau_{t}(x)=\tau_{t}(y)$ for all $x, y \in c$, so that we can also define $\tau_{t}(c)$.

Observe, using Algorithm 3.9.3, that

$$
\begin{align*}
& \text { for } x \notin \mathcal{B}_{M}, \quad Z_{t}(x)=\min \left(t-\tau_{t}(x), 1\right) \text { for all } t \in[0, T]  \tag{3.9.3}\\
& \text { for } q=1, \ldots, n, \quad Z_{t}\left(X_{q}\right)=\min \left(t-\tau_{t}\left(X_{q}\right), 1\right) \text { for all } t \in\left[0, T_{q}\right) \text {. } \tag{3.9.4}
\end{align*}
$$

Indeed, $\tau_{t}(x)$ stands for the last time before $t$ where $x$ was involved in a macroscopic fire (with the convention that a macroscopic fire occurs at time 0 ). Thus for $x \notin \mathcal{B}_{M}$, if $t-\tau_{t}(x) \geq 1, Z_{t}(x)=1$, and if $t-\tau_{t}(x)<1, Z_{t}(x)=t-\tau_{t}(x)$. For $x=X_{q}$, the same reasoning holds during $\left[0, T_{q}\right)$.

We also define for all $t \in[0, T]$, all $c \in \mathcal{C}_{M}$ and all $x \in(-A, A)$ here ( $c_{\lambda}$ is defined by (3.9.1) and $x_{\lambda}$ by (3.9.2))

$$
\begin{aligned}
\tau_{t}^{\lambda}(c) & =\sup \left\{s \leq t: \forall i \in c_{\lambda}, \eta_{T_{S} t-}^{\lambda}(i)=1 \text { and } \eta_{T_{S} t}^{\lambda}(i)=0\right\} \in[0, t] \\
\rho_{t}^{\lambda}(c) & =\sup \left\{s \leq t: \exists i \in c_{\lambda}, \eta_{T_{S} t-}^{\lambda}(i)=1 \text { and } \eta_{T_{S t}}^{\lambda}(i)=0\right\} \in[0, t] \\
\tau_{t}^{\lambda}(x) & =\sup \left\{s \leq t: \forall i \in x_{\lambda}, \eta_{T_{S t-}}^{\lambda}(i)=1 \text { and } \eta_{T_{S} t}^{\lambda}(i)=0\right\} \in[0, t]
\end{aligned}
$$

with the convention that $\eta_{0-}^{\lambda}(i)=1$ for all $i \in I_{A}^{\lambda}$. Observe that on $\Omega_{A, T}^{M}(\lambda)$, we have $\tau_{t}^{\lambda}(c), \rho_{t}^{\lambda}(c), \tau_{t}^{\lambda}(x) \in[0, t] \cap \mathcal{T}_{M}$ for all $t \in[0, T]$, all $c \in \mathcal{C}_{M}$ and all $x \in(-A, A)$.

For $t \in[0, T]$, consider the event

$$
\Omega_{t}^{\lambda}=\left\{\forall s \in[0, t], \forall c \in \mathcal{C}_{M}, \tau_{s}^{\lambda}(c)=\rho_{s}^{\lambda}(c)=\tau_{s}(c) \text { and } \forall x \in \mathcal{B}_{M}, \tau_{s}^{\lambda}(x)=\tau_{s}(x)\right\} .
$$

We define $\Omega_{t-}^{\lambda}$ similarly, replacing $[0, t]$ by $[0, t)$. The aim of the subsection is to prove the following result.

Lemma 3.9.5. - For any $\alpha>0$, any $\lambda \in\left(0, \lambda_{\alpha}\right), \Omega_{T}^{\lambda}$ a.s. holds on $\Omega(\alpha, \lambda)$.
Proof. - We work on $\Omega(\alpha, \lambda)$ and assume that $\lambda \in\left(0, \lambda_{\alpha}\right)$. Clearly, $\tau_{0}(x)=\tau_{0}^{\lambda}(x)=0$ and $\tau_{0}(c)=\tau_{0}^{\lambda}(c)=\rho_{0}^{\lambda}(c)=0$ for all $x \in \mathcal{B}_{M}$, all $c \in \mathcal{C}_{M}$, so that $\Omega_{0}^{\lambda}$ a.s. holds. We will show that for $q=0, \ldots, n-1, \Omega_{T_{q}}^{\lambda}$ implies $\Omega_{T_{q+1}}^{\lambda}$. This will prove that $\Omega_{T_{n}}^{\lambda}$ holds. The extension to $\Omega_{T}^{\lambda}$ will be straightforward (see step 1 below).

We thus fix $q \in\{0, \ldots, n-1\}$ and assume $\Omega_{T_{q}}^{\lambda}$. We repeatedly use below that on the time interval $\left(T_{q}, T_{q+1}\right)$, there are no fires at all (in $[-A, A]$ ) for the $\operatorname{LFF}_{A}(B S)$ process and no fires at all (in $\left.I_{A}^{\lambda}\right)$ during $\left(T_{S} T_{q}, T_{S} T_{q+1}\right)$ for the $\mathrm{FF}_{A}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process (use $\Omega_{A, T}^{M}(\lambda)$ ).

Step 1. - To start with, we observe that since there are no fires between $T_{S} T_{q}$ and $T_{S} T_{q+1}$, we have

$$
\tau_{t}^{\lambda}(x)=\tau_{T_{q}}^{\lambda}(x), \quad \tau_{t}^{\lambda}(c)=\tau_{T_{q}}^{\lambda}(c) \quad \text { and } \quad \rho_{t}^{\lambda}(c)=\rho_{T_{q}}^{\lambda}(c)
$$

for all $x \in \mathcal{B}_{M}$, all $c \in \mathcal{C}_{M}$, all $t \in\left[T_{q}, T_{q+1}\right.$ ) (because $\eta_{T_{S} t}^{\lambda}(i)$ is nondecreasing on $\left[T_{q}, T_{q+1}\right)$ for all $\left.i \in I_{A}^{\lambda}\right)$. By the same way,

$$
\tau_{t}(x)=\tau_{T_{q}}(x) \quad \text { and } \quad \tau_{t}(c)=\tau_{T_{q}}(c)
$$

for all $x \in \mathcal{B}_{M}$, all $c \in \mathcal{C}_{M}$, all $t \in\left[T_{q}, T_{q+1}\right)$ (because $Z_{t}(x), Z_{t}\left(x_{+}\right), Z_{t}\left(x_{-}\right)$are nondecreasing on $\left[T_{q}, T_{q+1}\right)$ for all $\left.x \in[-A, A]\right)$. Hence for $t \in\left[T_{q}, T_{q+1}\right), \Omega_{t}^{\lambda}=\Omega_{T_{q}}^{\lambda}$. Thus $\Omega_{T_{q}}^{\lambda}$ implies $\Omega_{T_{q+1}-}^{\lambda}$.

Step 2. - Let $c \in \mathcal{C}_{M}$. Observe that on $\Omega_{T_{q+1}-}^{\lambda}$, there holds, for all $i \in c_{\lambda}$,

$$
\begin{equation*}
\eta_{T_{S} T_{q+1}-}^{\lambda}(i)=\min \left(N_{T_{S} T_{q+1}-}^{S, 0}(i)-N_{T_{S} \tau_{T_{q}}(c)}^{S, 0}(i), 1\right) \tag{3.9.5}
\end{equation*}
$$

Indeed, seeds are falling on $i$ according to $\left(N_{t}^{S, 0}(i)\right)_{t \geq 0}$. Furthermore, we know from step 1 that

$$
\rho_{T_{q+1}-}^{\lambda}(c)=\tau_{T_{q+1}-}^{\lambda}(c)=\tau_{T_{q+1}-}(c)=\tau_{T_{q}}(c) .
$$

By definition of $\tau_{T_{q+1}-}^{\lambda}(c), \eta_{T_{S} \tau_{T_{q}}}^{\lambda}(i)=0$ for all $i \in c_{\lambda}$. And by definition of $\rho_{T_{q+1}-}^{\lambda}(c)$, no fire affects $c_{\lambda}$ during $\left(T_{S} \rho_{T_{q+1}-}^{\lambda}(c), T_{S} T_{q+1}\right)$.

Step 3. - We show here that if $Z_{T_{q+1}-}\left(X_{q+1}\right)<1$, there exist $j_{1}, j_{2}, j_{3}, j_{4}$ in $\left(X_{q+1}\right)_{\lambda}$ such that

$$
\begin{gathered}
j_{1}<j_{2}<\left\lfloor\boldsymbol{n}_{\lambda} X_{q+1}\right\rfloor<j_{3}<j_{4}, \\
\eta_{T_{S} T_{q+1}-}^{\lambda}\left(j_{2}\right)=\eta_{T_{S} T_{q+1}-}^{\lambda}\left(j_{3}\right)=0, \\
\eta_{T_{S} T_{q+1}-}^{\lambda}\left(j_{1}\right)=\eta_{T_{S} T_{q+1}-}^{\lambda}\left(j_{4}\right)=1 .
\end{gathered}
$$

Recall that for $i \in\left(X_{q+1}\right)_{\lambda}$, the seeds fall according to $\left(N_{t}^{S, q+1}\left(i-\left\lfloor\boldsymbol{n}_{\lambda} X_{q+1}\right\rfloor\right)\right)_{t \geq 0}$. Recall also that $\tau_{T_{q+1}-}^{\lambda}\left(X_{q+1}\right)=\tau_{T_{q+1}-}\left(X_{q+1}\right)$ (by Step 1), so that by definition, $\left(X_{q+1}\right)_{\lambda}$ is completely vacant at time $T_{S} \tau_{T_{q+1}-}\left(X_{q+1}\right)$. Recall finally that $\tau_{T_{q+1}-}\left(X_{q+1}\right) \in \mathcal{T}_{M}$ (and so does $T_{q+1}$ ).

Observe that by (3.9.4), $Z_{T_{q+1}-}\left(X_{q+1}\right)<1$ implies that $T_{q+1}-\tau_{T_{q+1}-}\left(X_{q+1}\right)<1$. Since we work on $\Omega_{2}^{S}(\lambda)$, we know that there are some sites

$$
i_{1}<i_{2}<i_{3}<\left\lfloor\boldsymbol{n}_{\lambda} X_{q+1}\right\rfloor<i_{4}<i_{5}<i_{6}
$$

in $\left(X_{q+1}\right)_{\lambda}$ such that at least one seed has fallen on $i_{2}$ and $i_{5}$ and no seed has fallen on $i_{1}, i_{3}, i_{4}, i_{6}$ during $\left[T_{S} \tau_{T_{q+1}-}\left(X_{q+1}\right), T_{S} T_{q+1}\right)$. All this implies that

$$
\eta_{T_{S} T_{q+1}-}^{\lambda}\left(i_{2}\right)=\eta_{T_{S} T_{q+1}-}^{\lambda}\left(i_{5}\right)=1 \quad \text { and } \quad \eta_{T_{S} T_{q+1}-}^{\lambda}\left(i_{3}\right)=\eta_{T_{S} T_{q+1}-}^{\lambda}\left(i_{4}\right)=0
$$

(because the vacant sites $i_{1}, i_{6}$ protect the occupied sites $i_{2}, i_{4}$ from fires falling outside $\left(X_{q+1}\right)_{\lambda}$ and because no fire falls on $\left(X_{q+1}\right)_{\lambda}$ during $\left.\left[0, T_{S} T_{q+1}\right)\right)$.

Step 4. - Next we check that if $Z_{T_{q+1}-}(c)=1$ for some $c \in \mathcal{C}_{M}$, then

$$
\eta_{T_{S} T_{q+1}-}^{\lambda}(i)=1 \quad \text { for all } i \in c_{\lambda} .
$$

Recalling (3.9.3), we see that $Z_{T_{q+1}-}(c)=1$ implies that $T_{q+1}-\tau_{T_{q+1}-}(c) \geq 1$ and thus $T_{q+1}-\tau_{T_{q}}(c) \geq 1$ by step 1 . Using (3.9.5), we conclude that for all $i \in c_{\lambda}$,

$$
\eta_{T_{S} T_{q+1}-}^{\lambda}(i)=\min \left(N_{T_{S} T_{q+1}-}^{S, 0}(i)-N_{T_{S} \tau_{T_{q}}(c)(i)}^{S, 0}, 1\right)=1
$$

(at least one seed falls on each site during a time interval of length greater than $T_{S}$ ).
Step 5. - We now prove that if $\widetilde{H}_{T_{q+1}-}(x)=0$ for some $x \in \mathcal{B}_{M}$,

$$
\eta_{T_{S} T_{q+1}-}^{\lambda}(i)=1 \quad \text { then for all } i \in x_{\lambda} .
$$

Preliminary considerations. - Let $k \in\{1, \ldots, n\}$ such that $x=X_{k}$, which is at the boundary of two cells $c_{-}, c_{+} \in \mathcal{C}_{M}$. We know that $\widetilde{H}_{T_{q+1}-}(x)=0$, whence $H_{T_{q+1}-}(x)=0$ and $Z_{T_{q+1}-}(x)=Z_{T_{q+1}-}\left(c_{+}\right)=Z_{T_{q+1}-}\left(c_{-}\right)=1$. This implies that $T_{q+1} \geq 1$, because $Z_{t}(x)=t$ for all $t<1$, all $x \in[-A, A]$.

No fire has concerned $\left(c_{-}\right)_{\lambda}$ during $\left(T_{S} \rho_{T_{q+1}-}^{\lambda}\left(c_{-}\right), T_{S} T_{q+1}\right)$ (by definition of $\rho_{T_{q+1}-}^{\lambda}\left(c_{-}\right)$). But step 1 implies that $\rho_{T_{q+1}-}^{\lambda}\left(c_{-}\right)=\tau_{T_{q+1}-}\left(c_{-}\right) \leq T_{q+1}-1$, because $Z_{T_{q+1}-}\left(c_{-}\right)=1$, see (3.9.3). Using a similar argument for $c_{+}$, we conclude that no
match falling outside $\left(X_{k}\right)_{\lambda}$ can affect $\left(X_{k}\right)_{\lambda}$ during $\left(T_{S}\left(T_{q+1}-1\right), T_{S} T_{q+1}\right)$ (because to affect $\left(X_{k}\right)_{\lambda}$, a match falling outside $\left(X_{k}\right)_{\lambda}$ needs to cross $c_{-}$or $\left.c_{+}\right)$.

Case 1. - First assume that $k \geq q+1$. Then we know that no fire has fallen on $\left(X_{k}\right)_{\lambda}$ during $\left[0, T_{S} T_{q+1}\right)$. Due to the preliminary considerations, we deduce that no fire at all has concerned $\left(X_{k}\right)_{\lambda}$ during $\left(T_{S}\left(T_{q+1}-1\right), T_{S} T_{q+1}\right)$. This time interval is of length greater than $T_{S}$. Thus $\left(X_{k}\right)_{\lambda}$ is completely occupied at time $T_{S} T_{q+1}-$.
Case 2. - Assume that $k \leq q$ and $Z_{T_{k}-}\left(X_{k}\right)=1$, so that there already has been a macroscopic fire in $\left(X_{k}\right)_{\lambda}$ (at time $\boldsymbol{a}_{\lambda} T_{k}$ ). Since then $Z_{T_{k}}\left(X_{k}\right)=0$ and $Z_{T_{q+1}-}\left(X_{k}\right)=1$, we deduce that $T_{q+1}-T_{k} \geq 1$. We conclude as in case 1 that no fire at all has concerned $\left(X_{k}\right)_{\lambda}$ during $\left(T_{S}\left(T_{q+1}-1\right), T_{S} T_{q+1}\right)$, which implies the claim.
Case 3. - Assume that $k \leq q$ and $Z_{T_{k}-}\left(X_{k}\right)<1$ and $T_{q+1}-T_{k} \geq 1$. Then there already has been a microscopic fire in $\left(X_{k}\right)_{\lambda}$ (at time $T_{S} T_{k}$ ). But there are no fire in $\left(X_{k}\right)_{\lambda}$ during $\left(T_{S} T_{k}, T_{S} T_{q+1}\right)$ and we conclude as in case 2.
Case 4. - Assume finally that $k \leq q$ and $Z_{T_{k}-}\left(X_{k}\right)<1$ and $T_{q+1}-T_{k}<1$. There has been a microscopic fire in $\left(X_{k}\right)_{\lambda}$ (at time $T_{S} T_{k}$ ). Since $H_{T_{q+1}-}\left(X_{k}\right)=0$, we deduce (see Algorithm 3.9.3) that $T_{k}+\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}^{k} \leq T_{q+1}$.
Consider the zone $C\left(\eta_{T_{S} T_{k}-}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} X_{k}\right\rfloor\right)$ destroyed by the match falling at time $T_{S} T_{k}$. This zone is completely occupied at time $T_{S}\left(T_{k}+\Theta_{\left.T_{k}-Z_{T_{k}-\left(X_{k}\right), T_{k}}\right)} \leq T_{S} T_{q+1}\right.$ by definition of $\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}$, see Lemma 3.9.1, using here again the preliminary considerations.

We deduce that $C\left(\eta_{T_{S} T_{k}-}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} X_{k}\right\rfloor\right)$ is completely occupied at time $T_{S} T_{q+1}-$.
Consider now $i \in\left(X_{k}\right)_{\lambda} \backslash C\left(\eta_{T_{S} T_{k}-}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} X_{k}\right\rfloor\right)$. Then $i$ has not been killed by the fire falling on $\left\lfloor\boldsymbol{n}_{\lambda} X_{k}\right\rfloor$. Thus $i$ cannot have been killed during $\left(T_{S}\left(T_{q+1}-1\right), T_{S} T_{q+1}\right)$ (due to the preliminary considerations) and is thus occupied at time $T_{S} T_{q+1}-$. This implies the claim.

Step 6. - Let us now prove that if $\widetilde{H}_{T_{q+1}-}(x)>0$ and $Z_{T_{q+1}-}\left(x_{+}\right)=1$ for some $x \in \mathcal{B}_{M}$, there are $i_{1}, i_{2} \in x_{\lambda}$ such that

$$
i_{1}<i_{2} \quad \text { and } \quad \eta_{T_{S} T_{q+1}-}^{\lambda}\left(i_{1}\right)=1, \quad \eta_{T_{S} T_{q+1}-}^{\lambda}\left(i_{2}\right)=0
$$

Recall that $x$ is at the boundary of two cells $c_{-}, c_{+}$. We have either $H_{T_{q+1}-}(x)>0$ or $Z_{T_{q+1}-}\left(c_{-}\right)<1$ (because $Z_{T_{q+1}-}\left(c_{+}\right)=1$ by assumption). Clearly, $x=X_{k}$ for some $k \leq q$, with $Z_{T_{k}-}\left(X_{k}\right)<1$ (else, we would have $H_{t}(x)=0$ and $Z_{t}\left(c_{-}\right)=Z_{t}\left(c_{+}\right)$ for all $t \in\left[0, T_{q+1}\right)$ ). Thus, recalling (3.9.4), $T_{k}-Z_{T_{k}-}\left(X_{k}\right)=\tau_{T_{k}-}\left(X_{k}\right)=\tau_{T_{k}-}^{\lambda}\left(X_{k}\right)$, so that $\left(X_{k}\right)_{\lambda}$ is completely empty at time $T_{S}\left(T_{k}-Z_{T_{k}-}\left(X_{k}\right)\right)$.

Case 1. - Assume first that $H_{T_{q+1}-}(x)>0$. Then by construction, see Algorithm 3.9.3,

$$
T_{k}+\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}^{k}>T_{q+1}>T_{k}
$$

Consider $C=C\left(\eta_{T_{S} T_{k}-}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} X_{k}\right\rfloor\right)$. By $\Omega_{2}^{S}(\lambda)$, we have

$$
C \subset\left[\left[\left\lfloor\boldsymbol{n}_{\lambda} X_{k}-\frac{1}{2} \boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\boldsymbol{n}_{\lambda} X_{k}+\frac{1}{2} \boldsymbol{m}_{\lambda}\right\rfloor\right\rfloor\right],
$$

because $T_{k}-Z_{T_{k}-}\left(X_{k}\right)$ and $T_{k}$ belong to $\mathcal{T}_{M}$ and $0<Z_{T_{k}-}\left(X_{k}\right)<1$. The component $C$ is destroyed at time $T_{S} T_{k}$. By Definition of $\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}^{k}$, see Lemma 3.9.1, we deduce that $C$ is not completely occupied at time

$$
T_{S} T_{q+1}<T_{S}\left(T_{k}+\Theta_{T_{k}-Z_{T_{k}-}-\left(X_{k}\right), T_{k}}^{k}\right)
$$

Consequenty, there is $i_{2} \in \llbracket\left\lfloor\boldsymbol{n}_{\lambda} X_{k}-\frac{1}{2} \boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\boldsymbol{n}_{\lambda} X_{k}+\frac{1}{2} \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$ such that

$$
\eta_{T_{S} T_{q+1}-}^{\lambda}\left(i_{2}\right)=0
$$

Finally, using again $\Omega_{2}^{S}(\lambda)$ there is necessarily (at least) one seed falling on a site in $\llbracket\left\lfloor\boldsymbol{n}_{\lambda} X_{k}-\boldsymbol{m}_{\lambda}+1\right\rfloor,\left\lfloor\boldsymbol{n}_{\lambda} X_{k}-\frac{1}{2} \boldsymbol{m}_{\lambda}-1\right\rfloor \rrbracket \subset\left(X_{k}\right)_{\lambda}$ during $\left(T_{S} T_{q}, T_{S} T_{q+1}\right)$. This shows the result.
Case 2. - Assume next that $H_{T_{q+1}-}(x)=0$ and that

$$
T_{q+1}-\left[T_{k}-Z_{T_{k}-}\left(X_{k}\right)\right]<1 .
$$

Recall that $\left(X_{k}\right)_{\lambda}$ is completely empty at time $T_{S}\left(T_{k}-Z_{T_{k}-}\left(X_{k}\right)\right)$. Since $T_{k}-Z_{T_{k}-}\left(X_{k}\right)$ and $T_{q+1}$ belong to $\mathcal{T}_{M}$ and since their difference is smaller than 1 by assumption, $\Omega_{2}^{S}(\lambda)$ guarantees us the existence of $i_{1}<i_{2}<i_{3}$, all in $\left(X_{k}\right)_{\lambda}$, such that (at least) one seed falls on $i_{2}$ and no seed fall on $i_{1}$ nor on $i_{3}$ during $\left(T_{S}\left(T_{k}-Z_{T_{k}-}\left(X_{k}\right)\right), T_{S} T_{q+1}\right)$. One easily concludes that $i_{2}$ is occupied and $i_{3}$ is vacant at time $T_{S} T_{q+1}-$, as desired.
Case 3. - Assume finally that $H_{T_{q+1}-}(x)=0$ and that

$$
T_{q+1}-\left[T_{k}-Z_{T_{k}-}\left(X_{k}\right)\right] \geq 1
$$

Since $H_{T_{q+1}-}(x)=0$, there holds $Z_{T_{q+1}-}\left(c_{-}\right)<1=Z_{T_{q+1}-}\left(c_{+}\right)$and $T_{k}+\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}^{k} \leq T_{q+1}$. We aim to use the event $\Omega_{1}^{S}(\lambda)$. We introduce

$$
t_{0}=T_{k}-Z_{T_{k}-}\left(X_{k}\right)=\tau_{T_{k}-}\left(X_{k}\right)=\tau_{T_{k}-}^{\lambda}\left(X_{k}\right)
$$

Observe that $\tau_{T_{k}-}\left(c_{-}\right)=\tau_{T_{k}-}\left(c_{+}\right)=\tau_{T_{k}-}(x)$ because there is no match falling (exactly) on $x$ during $\left[0, T_{k}\right)$. Thus $Z_{t_{0}}(x)=Z_{t_{0}}\left(c_{-}\right)=Z_{t_{0}}\left(c_{+}\right)=0$.

Set now $t_{1}=T_{k}$ and $s=T_{q+1}$. Observe that $0<t_{1}-t_{0}<1$ (because $\left.Z_{T_{k}-}\left(X_{k}\right)<1\right)$. Necessarily, $Z_{t}\left(c_{-}\right)$has jumped to 0 at least one time between $t_{0}$ and $T_{q+1}-$ (else, one would have $Z_{T_{q+1}-}\left(c_{-}\right)=1$, since $T_{q+1}-t_{0} \geq 1$ by assumption) and this jump occurs after $t_{0}+1>t_{1}$ (since a jump of $Z_{t}\left(c_{-}\right)$requires that $Z_{t}\left(c_{-}\right)=1$, and since for all $\left.t \in\left[t_{0}, t_{0}+1\right), Z_{t}\left(c_{-}\right)=t-t_{0}<1\right)$.

We thus may denote by $t_{2}<t_{3}<\cdots<t_{K}$, for some $K \geq 2$, the successive times of jumps of the process $\left(Z_{t}\left(c_{-}\right), Z_{t}\left(c_{+}\right)\right)$during $\left(t_{0}+1, s\right)$. We also put $\varepsilon=1$ if $t_{2}$ is a jump of $Z_{t}\left(c_{+}\right)$and $\varepsilon=-1$ else. Then we observe that $Z_{t}\left(c_{-}\right)$and $Z_{t}\left(c_{+}\right)$do never jump to 0 at the same time during $\left(t_{0}, s\right.$ ] (else, it would mean that they are killed by
the same fire at some time $u$, whence necessarily, $H_{r}(u)=0$ and $Z_{r}\left(c_{-}\right)=Z_{r}\left(c_{+}\right)$for all $r \in(u, s])$.

Furthermore, there is always at least one jump of $\left(Z_{t}\left(c_{-}\right), Z_{t}\left(c_{+}\right)\right)$in any time interval of length 1 (during $\left[t_{0}+1, s\right)$ ), because else, $Z_{t}\left(c_{+}\right)$and $Z_{t}\left(c_{-}\right)$would both become equal to 1 and thus would remain equal forever.

Finally, observe that two jumps of $Z_{t}\left(c_{-}\right)$cannot occur in a time interval of length 1 (since a jump of $Z_{t}\left(c_{-}\right)$requires that $Z_{t}\left(c_{-}\right)=1$ ) and the same thing holds for $c_{+}$.

Consequently, the family $\mathcal{R}=\left\{\varepsilon, t_{0}, \ldots, t_{K} ; s\right\}$ necessarily satisfies condition (PP).
Next, $t_{2}-t_{1}<\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}^{k}=\Theta_{t_{0}, t_{1}}^{k}$, because else, we would have $H_{t_{2}-}\left(X_{k}\right)=0$ and thus the fire destroying $c_{+}$(or $c_{-}$) at time $t_{2}$ would also destroy $c_{-}$(or $c_{+}$), we thus would have $Z_{t_{2}}\left(c_{+}\right)=Z_{t_{2}}\left(c_{-}\right)=0$, so that $Z_{t}\left(c_{+}\right)$and $Z_{t}\left(c_{-}\right)$would remain equal forever.

Finally, we check that $\left(\eta_{T_{S} t}^{\lambda}(i)\right)_{t \geq t_{0}, i \in x_{\lambda}}=\left(\zeta_{t}^{\lambda, \mathcal{R}, k}\left(i+\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor\right)\right)_{t \geq t_{0}, i \in x_{\lambda}}$, this last process being built with the family of seed processes $\left(N_{T_{S} t}^{S, k}(i)\right)_{t \geq t_{0}, i \in x_{\lambda}}$ as in subsection 3.9.2. Both are empty at time $t_{0}$. Seeds fall according to the same processes. In both cases, a first match falls on $\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor$ at time $t_{1}$. In both cases (say that $\varepsilon=1$ ) a fire destroys the occupied connected component containing $\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor+\boldsymbol{m}_{\lambda}$ at time $t_{2}$ (by definition for $\zeta^{\lambda, \mathcal{R}}$ and since $Z_{t_{2}-}\left(c_{+}\right)=1$ implies, exactly as in step 4 , that $\eta_{T_{S} t_{2}-}^{\lambda}(i)=1$ for all $i$ in $\left(c_{+}\right)_{\lambda}$, so that the fire destroying $c_{+}$at time $t_{2}$ also destroys the occupied connected component around $\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor+\boldsymbol{m}_{\lambda}$, which is at the boundary of $c_{+}$). And so on.

We thus can use $\Omega_{1}^{S}(\lambda)$ and conclude that there are some sites $i_{1}<i_{2}$ in $x_{\lambda}$ with $\eta_{T_{S} T_{q+1-}}^{\lambda}\left(i_{1}\right)=1$ and $\eta_{T_{S} T_{q+1-}}^{\lambda}\left(i_{2}\right)=0$ as desired.

Step 7. - We finally conclude the proof. We put $z:=Z_{T_{q+1}-}\left(X_{q+1}\right)$ and consider separately the cases where $z \in(0,1)$ and $z=1$. Observe that $z=0$ never happens, since by construction, $Z_{T_{q+1}-}\left(X_{q+1}\right)=\min \left(Z_{T_{q}}\left(X_{q+1}\right)+\left(T_{q+1}-T_{q}\right), 1\right)>0$ and since $T_{q+1}>T_{q}$.

Case $z \in(0,1) .-$ Then in the $\operatorname{LFF}_{A}(B S)$-process, see Algorithm 3.9.3,

$$
Z_{T_{q+1}}(x)=Z_{T_{q+1}-}(x)>0 \quad \text { for all } x \in[-A, A],
$$

whence $\tau_{T_{q+1}}(x)=\tau_{T_{q+1}-}(x)$ and $\tau_{T_{q+1}}(c)=\tau_{T_{q+1}-}(c)$ for all $x \in \mathcal{B}_{M}$, all $c \in \mathcal{C}_{M}$.
Using step 3, we see that the match falling on $\left\lfloor\boldsymbol{n}_{\lambda} X_{q+1}\right\rfloor$ at time $T_{S} T_{q+1}$ destroys nothing outside $\llbracket j_{2}+1, j_{3}-1 \rrbracket$. As a conclusion, we obviously have

$$
\tau_{T_{q+1}}^{\lambda}(x)=\tau_{T_{q+1}-}^{\lambda}(x) \quad \text { and } \quad \rho_{T_{q+1}}^{\lambda}(c)=\tau_{T_{q+1}}^{\lambda}(c)=\tau_{T_{q+1}-}^{\lambda}(c)
$$

for all $x \in \mathcal{B}_{M} \backslash\left\{X_{q+1}\right\}$ and all $c \in \mathcal{C}_{M}$. There also holds $\tau_{T_{q+1}}^{\lambda}\left(X_{q+1}\right)=\tau_{T_{q+1}-}^{\lambda}(x)$ because $j_{1}$ (see step 3), which is occupied at time $T_{S} T_{q+1}-$ and not killed at time $T_{S} T_{q+1}$ (thanks to $j_{2}$ ), does belong to $\left(X_{q+1}\right)_{\lambda}$.

We conclude that when $z \in(0,1), \Omega_{T_{q+1}-}^{\lambda}$ implies $\Omega_{T_{q+1}}^{\lambda}$. Using Step 1 , we deduce that $\Omega_{T_{q}}^{\lambda}$ implies $\Omega_{T_{q+1}}^{\lambda}$ when $z \in(0,1)$.

Case 1. - Then there are $a, b \in \mathcal{B}_{M} \cup\{-A, A\}$ such that $D_{T_{q+1}-}\left(X_{q+1}\right)=[a, b]$. We assume that $a, b \in \mathcal{B}_{M}$, the other cases being treated similarly. Recalling Algorithm 3.9.3, we know that for all $c \in \mathcal{C}_{M}$ with $c \subset(a, b), Z_{T_{q+1}-}(c)=1$, for all $x \in \mathcal{B}_{M} \cap(a, b), \widetilde{H}_{T_{q+1}-}(x)=0$, while finally $\widetilde{H}_{T_{q+1}-}(a)>0$ and $\widetilde{H}_{T_{q+1}-}(b)>0$.
For the $\operatorname{LFF}_{A}(B S)$-process, we have
(i) $\tau_{T_{q+1}}(c)=T_{q+1}$ for all $c \in \mathcal{C}_{M}$ with $c \subset(a, b)$;
(ii) $\tau_{T_{q+1}}(x)=T_{q+1}$ for all $x \in \mathcal{B}_{M} \cap(a, b)$;
(iii) $\tau_{T_{q+1}}(c)=\tau_{T_{q+1}-}(c)$ for all $c \in \mathcal{C}_{M}$ with $c \cap(a, b)=\varnothing$;
(iv) $\tau_{T_{q+1}}(x)=\tau_{T_{q+1}-}(x)$ for all $x \in \mathcal{B}_{M} \backslash(a, b)$.

Next, using steps 4,5 , using step 6 for $a$ (and a very similar result for $b$ ), we immediately check that the fire occurring at $\left\lfloor\boldsymbol{n}_{\lambda} X_{q+1}\right\rfloor$ at time $T_{S} T_{q+1}$
$\triangleright$ destroys completely all the cells $c \in \mathcal{C}_{M}$ with $c \subset(a, b)$;
$\triangleright$ destroys completely all the zones $x_{\lambda}$ with $x \in \mathcal{B}_{M} \cap(a, b)$;
$\triangleright$ does not destroy at all the cells $c \in \mathcal{C}_{M}$ with $c \cap(a, b)=\varnothing$ and the zones $x_{\lambda}$ with $x \in \mathcal{B}_{M} \backslash[a, b] ;$
$\triangleright$ does not destroy completely $a_{\lambda}$ nor $b_{\lambda}$.
Consequently, we have
(i) $\rho_{T_{q+1}}^{\lambda}(c)=\tau_{T_{q+1}}^{\lambda}(c)=T_{q+1}$ for all $c \in \mathcal{C}_{M}$ with $c \subset(a, b)$;
(ii) $\tau_{T_{q+1}}^{\lambda}(x)=T_{q+1}$ for all $x \in \mathcal{B}_{M} \cap(a, b)$;
(iii) $\rho_{T_{q+1}}^{\lambda}(c)=\rho_{T_{q+1}-}^{\lambda}(c)$ and $\tau_{T_{q+1}}^{\lambda}(c)=\tau_{T_{q+1}-}^{\lambda}(c)$ for all $c \in \mathcal{C}_{M}$ with $c \cap(a, b)=$
(iv) $\tau_{T_{q+1}}^{\lambda}(x)=\tau_{T_{q+1}-}^{\lambda}(x)$ for all $x \in \mathcal{B}_{M} \backslash(a, b)$.

We conclude that when $z=1, \Omega_{T_{q+1}-}^{\lambda}$ implies $\Omega_{T_{q+1}}^{\lambda}$. Using step 1, we deduce that $\Omega_{T_{q}}^{\lambda}$ implies $\Omega_{T_{q+1}}^{\lambda}$ when $z=1$.
3.9.6. Conclusion. - To achieve the proof, we will need the following result.

Lemma 3.9.6. - Let $\left(N_{t}^{S}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ be a family of i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes.
(i) Put $K_{t}^{\lambda}=\left(2 \boldsymbol{m}_{\lambda}+1\right)^{-1}\left|\left\{i \in \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket: N_{T_{S} t}^{S}(i)>0\right\}\right|$ and

$$
U_{t}^{\lambda}=\left(\frac{\psi_{S}\left(K_{t}^{\lambda}\right)}{T_{S}}\right) \wedge 1
$$

recall notation 2.1.5. Then for any $T>0, \sup _{[0, T]}\left|U_{t}^{\lambda}-t \wedge 1\right|$ tends a.s. to 0 as $\lambda$ tends to 0 .
(ii) For any $k \geq 0, \operatorname{Pr}\left[\left|C\left(\min \left(N_{T_{S} t}^{S}, 1\right), 0\right)\right|=k\right]=q_{k}(t \wedge 1)$, where $q_{k}(z)$ was defined (2.4.2).

Proof. - We start with (i). First observe that $t \mapsto U_{t}^{\lambda}$ and $t \mapsto t \wedge 1$ are nondecreasing and $t \mapsto t \wedge 1$ is continuous. By the Dini Theorem, it suffices to prove that for all $t \in[0, T]$, a.s., $\lim U_{t}^{\lambda}=t \wedge 1$. To do so, observe that $\left(2 m_{\lambda}+1\right) K_{t}^{\lambda}$ has a binomial distribution with parameters $2 \boldsymbol{m}_{\lambda}+1$ and $\nu_{S}\left(\left(0, T_{S} t\right)\right)$. Thus $K_{t}^{\lambda}$ tends a.s. to $\nu_{S}\left(\left(0, T_{S} t\right)\right)$. Hence $U_{t}^{\lambda}$ tends a.s. to $\left(\psi_{S}\left(\nu_{S}\left(\left(0, T_{S} t\right)\right)\right) / T_{S}\right) \wedge 1=t \wedge 1$ by definition of $\psi_{S}$.

We now check (ii). If $t \geq 1$, then obviously, $\min \left(N_{T_{S} t}^{S}(i), 1\right)=1$ for all $i \in \mathbb{Z}$, whence $\left|C\left(\min \left(N_{T_{S} t}^{S}, 1\right), 0\right)\right|=\infty$ a.s. Consequently,

$$
\operatorname{Pr}\left[\left|C\left(\min \left(N_{T_{S} t}^{S}, 1\right), 0\right)\right|=k\right]=0=q_{k}(1)
$$

For $t<1$, the result relies on a simple computation involving the i.i.d. random variables $\min \left(N_{T_{S} t}^{S}(i), 1\right)$, which have a Bernoulli distribution with parameter $\nu_{S}\left(\left(0, T_{S} t\right)\right)$ : if $k=0$, there holds

$$
\operatorname{Pr}\left[\left|C\left(\min \left(N_{T_{S} t}^{S}, 1\right), 0\right)\right|=0\right]=\operatorname{Pr}\left[N_{T_{S} t}(i)=0\right]=\nu_{S}\left(\left(T_{S} t, T_{S}\right)\right)=q_{0}(t)
$$

For $k \geq 1$,

$$
\begin{aligned}
\operatorname{Pr} & {\left[\left|C\left(\min \left(N_{T_{S} t}^{S}, 1\right), 0\right)\right|=k\right] } \\
& =\sum_{j=0}^{k-1} \operatorname{Pr}\left[N_{T_{S} t}^{S}(j-k)=N_{T_{S} t}^{S}(j+1)=0, \forall i \in \llbracket j-k+1, j \rrbracket, N_{T_{S} t}^{S}(i)=1\right] \\
& =k\left[\nu_{S}\left(\left(T_{S} t, T_{S}\right)\right)\right]^{2} \cdot\left[\nu_{S}\left(\left(0, T_{S} t\right)\right)\right]^{k}=q_{k}(t),
\end{aligned}
$$

which ends the proof.
We finally give the
Proof of Proposition 3.8.1 when $\beta=B S$. - Let us fix $x_{0} \in(-A, A), t_{0} \in(0, T]$ and $\varepsilon>0$. We will prove that with our coupling (see subsection 3.9.3), there holds
(a) $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\boldsymbol{\delta}\left(D_{t_{0}}^{\lambda}\left(x_{0}\right), D_{t_{0}}\left(x_{0}\right)\right)>\varepsilon\right]=0$;
(b) $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\boldsymbol{\delta}_{T}\left(D^{\lambda}\left(x_{0}\right), D\left(x_{0}\right)\right)>\varepsilon\right]=0$;
(c) $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\sup _{[0, T]}\left|Z_{t}^{\lambda}\left(x_{0}\right)-Z_{t}^{\lambda}\left(x_{0}\right)\right| \geq \varepsilon\right]=0$;
(d) $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|C\left(\eta_{T_{S} t_{0}}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor\right)\right|=k\right]=\mathbb{E}\left[q_{k}\left(Z_{t}\left(x_{0}\right)\right)\right]$.

Recall that $q_{k}(z)$ was defined, for $k \geq 0$ and $z \in[0,1]$ in (2.4.2). These points will clearly imply the result.

First, we introduce, for $\zeta>0$, the event $\Omega_{A, T}^{x_{0}}(\zeta)$ on which $x_{0} \notin \bigcup_{q=1}^{n}\left[X_{q}-\zeta, X_{q}+\zeta\right]$. The probability of this event obviously tends to 1 as $\zeta \rightarrow 0$.

On $\Omega_{A, T}^{x_{0}}(\zeta)$, for $\lambda>0$ small enough (say, small enough such that $4 \boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}<\zeta$ ), $\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor \notin \bigcup_{q=1}^{n}\left(X_{q}\right)_{\lambda}$. We then call $c_{0} \in \mathcal{C}_{M}$ the cell containing $x_{0}$.

Step 1. - We first show that (a) (which holds for an arbitrary value of $\left.t_{0} \in(0, T]\right)$ implies (b).

Indeed, we have by construction, for any $t \in[0, T], \boldsymbol{\delta}\left(D_{t}^{\lambda}\left(x_{0}\right), D_{t}\left(x_{0}\right)\right)<4 A$. Hence by dominated convergence, (a) implies that $\lim _{\lambda \rightarrow 0} \mathbb{E}\left[\boldsymbol{\delta}\left(D_{t}^{\lambda}\left(x_{0}\right), D_{t}\left(x_{0}\right)\right)\right]=0$, whence again by dominated convergence, $\lim _{\lambda \rightarrow 0} \mathbb{E}\left[\boldsymbol{\delta}_{T}\left(D^{\lambda}\left(x_{0}\right), D\left(x_{0}\right)\right)\right]=0$.

Step 2. - Due to Lemma 3.9.5, we know that on $\Omega(\alpha, \lambda) \cap \Omega_{A, T}^{x_{0}}(\zeta)$, we have

$$
\tau_{t}^{\lambda}\left(c_{0}\right)=\rho_{t}^{\lambda}\left(c_{0}\right)=\tau_{t}\left(x_{0}\right) \quad \text { for all } t \in[0, T] .
$$

This implies that for all $i \in\left(c_{0}\right)_{\lambda}$, for all $t \in[0, T]$,

$$
\eta_{T_{S} t}^{\lambda}(i)=\min \left(N_{T_{S} t}^{S, 0}(i)-N_{T_{S} \tau_{t}\left(x_{0}\right)}^{S, 0}(i), 1\right) .
$$

We also recall that by construction, $\left(\tau_{t}\left(x_{0}\right)\right)_{t \geq 0}$ is independent of $\left(N_{t}^{S, 0}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$.
Step 3. - Here we prove (d), for some fixed $k \geq 0$. Let $\delta>0$ be fixed. We first consider $\alpha_{0}>0, \zeta_{0}>0$ and $\lambda_{0}>0$ such that for all $\lambda \in\left(0, \lambda_{0}\right)$,

$$
\operatorname{Pr}\left[\Omega\left(\alpha_{0}, \lambda\right) \cap \Omega_{A, T}^{x_{0}}\left(\zeta_{0}\right)\right]>1-\delta
$$

Then we consider $\lambda_{k} \leq \lambda_{0}$ in such a way that for $\lambda \in\left(0, \lambda_{k}\right)$,

$$
\left[\left[\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor-k-1,\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor+k+1\right]\right] \subset\left(c_{0}\right)_{\lambda}
$$

on $\Omega_{A, T}^{x_{0}}\left(\zeta_{0}\right)$ (it suffices that $2 k<\zeta_{0} \boldsymbol{n}_{\lambda}$ for all $\lambda \in\left(0, \lambda_{k}\right)$ ).
We easily conclude: for $\lambda \in\left(0, \lambda_{k}\right)$, recalling (3.9.3), using Lemma 3.9 .6 (ii) together with a (spatial and temporal) stationarity argument, using step 2 and that $\left(N_{t}^{S, 0}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ is independent of $\Omega_{A, T}^{x_{0}}(\zeta) \cap \Omega(\alpha, \lambda)$ and $\tau_{t}\left(x_{0}\right)$, we obtain

$$
\begin{aligned}
& \left|\operatorname{Pr}\left[\left|C\left(\eta_{T_{S} t}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor\right)\right|=k\right]-\mathbb{E}\left[q_{k}\left(Z_{t}\left(x_{0}\right)\right)\right]\right| \\
& \quad=\left|\operatorname{Pr}\left[\left|C\left(\eta_{T_{S} t}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor\right)\right|=k\right]-\mathbb{E}\left[q_{k}\left(\min \left(t-\tau_{t}\left(x_{0}\right), 1\right)\right)\right]\right| \\
& \quad \leq \operatorname{Pr}\left[\left(\Omega(\alpha, \lambda) \cap \Omega_{A, T}^{x_{0}}(\zeta)\right)^{c}\right]<\delta .
\end{aligned}
$$

This concludes the proof of (d).
Step 4. - We next prove (c). For $\delta>0$ fixed, we consider $\alpha_{0}>0, \zeta_{0}>0$ and $\lambda_{0}>0$ be as in step 3. Consider the successive values $0=s_{0}<s_{1}<\cdots<s_{\ell}<T$ of $\left(\tau_{t}\left(x_{0}\right)\right)_{t \in[0, T]}$. Set also $s_{\ell+1}=T$. Recall the definition of $Z_{t}^{\lambda}(x)$, see $(2.2 .5)$, and compare to Lemma 3.9.6(i). Let $k \in\{0, \ldots, \ell\}$ be fixed. Denote by $\left(U_{t}^{k, \lambda}\right)_{t \geq 0}$ the process defined as in Lemma 3.9.6(i) with the seed process

$$
\left(N_{s_{k} / T_{S}+t}^{S, 0}\left(i-\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor\right)-N_{s_{k} / T_{S}}^{S, 0}\left(i-\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor\right)\right)_{t \geq 0, i \in \mathbb{Z}}
$$

(this is indeed a family of $\operatorname{SR}\left(\mu_{S}\right)$-processes by stationarity and since $s_{1}, \ldots, s_{\ell}$ are independent of $\left.\left(N_{t}^{S, 0}(i)\right)_{t \geq 0, i \in \mathbb{Z}}\right)$. Then due to Lemma 3.9.6(i), for all $\lambda>0$ small enough, say $\lambda \in\left(0, \lambda_{1}\right)$,

$$
\operatorname{Pr}\left(\sup _{\left[s_{k}, s_{k+1}\right)}\left|U_{t-s_{k}}^{k, \lambda}-\left(t-s_{k}\right) \wedge 1\right| \geq \varepsilon\right) \leq \delta .
$$

But on $\Omega(\alpha, \lambda) \cap \Omega_{A, T}^{x_{0}}(\zeta)$, we have $Z_{t}^{\lambda}\left(x_{0}\right)=U_{t-s_{k}}^{k, \lambda}$ for all $t \in\left[s_{k}, s_{k+1}\right)$, see step 2. It also holds, recall (3.9.3), that $Z_{t}\left(x_{0}\right)=\left(t-s_{k}\right) \wedge 1$ for $t \in\left[s_{k}, s_{k+1}\right)$. As a conclusion, for all $\lambda>0$ small enough,

$$
\begin{aligned}
\operatorname{Pr}\left(\sup _{\left[s_{k}, s_{k+1}\right)}\left|Z_{t}^{\lambda}\left(x_{0}\right)-Z_{t}\left(x_{0}\right)\right| \geq \varepsilon\right) \leq & \operatorname{Pr}\left(\left(\Omega(\alpha, \lambda) \cap \Omega_{A, T}^{x_{0}}(\zeta)\right)^{c}\right) \\
& +\operatorname{Pr}\left(\sup _{\left[s_{k}, s_{k+1}\right)}\left|U_{t-s_{k}}^{k, \lambda}-\left(t-s_{k}\right) \wedge 1\right| \geq \varepsilon\right) \leq 2 \delta .
\end{aligned}
$$

Observing finally that $\ell \leq \pi_{M}([0, T] \times(-A, A))$ and that

$$
\mathbb{E}\left[\pi_{M}([0, T] \times(-A, A))\right]=2 T A
$$

we easily deduce that for all $\lambda>0$ small enough,

$$
\operatorname{Pr}\left(\sup _{[0, T]}\left|Z_{t}^{\lambda}\left(x_{0}\right)-Z_{t}\left(x_{0}\right)\right| \geq \varepsilon\right) \leq 2 T A \delta .
$$

Point (c) immediately follows.
Step 5. - It remains to prove (a). Let $\delta>0$. Put $\mathcal{T}_{M}^{*}=\mathcal{T}_{M} \cup\left\{t_{0}\right\}$. Define the events $\Omega_{M}^{*}(\alpha), \Omega_{1}^{S, *}(\lambda)$ and $\Omega_{2}^{S, *}(\lambda)$ as $\Omega_{M}(\alpha), \Omega_{1}^{S}(\lambda)$ and $\Omega_{2}^{S}(\lambda)$, replacing $\mathcal{T}_{M}$ by $\mathcal{T}_{M}^{*}$. Define also $\Omega^{*}(\lambda, \alpha)=\Omega_{A, T}^{M}(\lambda) \cap \Omega_{M}^{*}(\alpha) \cap \Omega_{1}^{S, *}(\lambda) \cap \Omega_{2}^{S, *}(\lambda)$. Clearly, choosing $\alpha_{1}>0$ and $\zeta_{1}>0$ small enough, we have $\operatorname{Pr}\left[\Omega^{*}\left(\lambda, \alpha_{1}\right) \cap \Omega_{A, T}^{x_{0}}\left(\zeta_{1}\right)\right] \geq 1-\delta$ for all $\lambda>0$ small enough, say $\lambda \in\left(0, \lambda_{2}\right)$. On $\Omega^{*}\left(\lambda, \alpha_{1}\right) \cap \Omega_{A, T}^{x_{0}}\left(\zeta_{1}\right)$, we can argue exactly as in the proof of Lemma 3.9.5 to check that
(i) if $Z_{t_{0}}\left(x_{0}\right)<1$, then $D_{t_{0}}\left(x_{0}\right)=\left\{x_{0}\right\}$ and $C\left(\eta_{T_{S} t}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor\right) \subset\left(x_{0}\right)_{\lambda}$ (see Step 3 of the proof of Lemma 3.9.5), whence $D_{t_{0}}^{\lambda}\left(x_{0}\right) \subset\left[x_{0}-\boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}, x_{0}+\boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}\right]$. We deduce that $\boldsymbol{\delta}\left(D_{t_{0}}\left(x_{0}\right), D_{t_{0}}^{\lambda}\left(x_{0}\right)\right) \leq 2 \boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}$;
(ii) if $Z_{t_{0}}\left(x_{0}\right)=1$ and $D_{t_{0}}\left(x_{0}\right)=[a, b]$ for some $a, b \in \mathcal{B}_{M} \cup\{-A, A\}$, then
$\triangleright$ for all $c \in \mathcal{C}_{M}$ with $c \subset[a, b], \eta_{T_{S} t}^{\lambda}(i)=1$ for all $i \in c_{\lambda}$ (see Step 4 of the preceding proof);
$\triangleright$ for all $x \in \mathcal{B}_{M} \cap(a, b), \eta_{T_{S} t}^{\lambda}(i)=1$ for all $i \in x_{\lambda}$ (see step 5 of the preceding proof);
$\triangleright$ there are $i \in a_{\lambda}$ and $j \in b_{\lambda}$ such that $\eta_{T_{S} t}^{\lambda}(i)=\eta_{T_{S} t}^{\lambda}(j)=0$ (see step 6 of the preceding proof);
so that

$$
\left[\left[\left\lfloor\boldsymbol{n}_{\lambda} a\right\rfloor+\boldsymbol{m}_{\lambda}+1,\left\lfloor\boldsymbol{n}_{\lambda} b\right\rfloor-\boldsymbol{m}_{\lambda}-1\right]\right] \subset C\left(\eta_{T_{S} t}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor\right) \subset\left[\left[\left\lfloor\boldsymbol{n}_{\lambda} a\right\rfloor-\boldsymbol{m}_{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} b\right\rfloor+\boldsymbol{m}_{\lambda}\right]\right]
$$

and thus

$$
\left[a+\boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}, b-\boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}\right] \subset D_{t_{0}}^{\lambda}\left(x_{0}\right) \subset\left[a-\boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}, b+\boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}\right],
$$

whence as previously, $\boldsymbol{\delta}\left(D_{t_{0}}\left(x_{0}\right), D_{t_{0}}^{\lambda}\left(x_{0}\right)\right) \leq 2 \boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}$. Thus for all $\lambda \in\left(0, \lambda_{2}\right)$, on $\Omega^{*}\left(\lambda, \alpha_{1}\right) \cap \Omega_{A, T}^{x_{0}}\left(\zeta_{1}\right)$, we always have

$$
\boldsymbol{\delta}\left(D_{t_{0}}\left(x_{0}\right), D_{t_{0}}^{\lambda}\left(x_{0}\right)\right) \leq 2 \boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}
$$

We conclude that for $\delta>0$, for all $\lambda \in\left(0, \lambda_{2}\right)$ small enough (so that $2 \boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}<\varepsilon$ ), there holds

$$
\operatorname{Pr}\left[\boldsymbol{\delta}\left(D_{t_{0}}\left(x_{0}\right), D_{t_{0}}^{\lambda}\left(x_{0}\right)\right)>\varepsilon\right] \leq \operatorname{Pr}\left[\left(\Omega^{*}(\lambda, \alpha) \cap \Omega_{A, T}^{x_{0}}(\zeta)\right)^{c}\right]<\delta
$$

This concludes the proof.

### 3.10. Convergence proof when $\beta=\infty$

The aim of this section is to prove Proposition 3.8 .1 in the case where $\beta=\infty$ and this will conclude the proof of Theorem 2.3.3. This section generalizes consequently [15, section 4] and the proof we present here is quite different and slightly less intricate. We follow essentially the ideas of the previous section. Some points are easier (because the height of the barriers are deterministic in the limit process), but some other points are more complicated (in particular, the height of the barriers are not constant as a function of $\lambda$ ).

In the whole section, we assume $\left(H_{M}\right)$ and $\left(H_{S}(\infty)\right)$. The parameters $A>0$ and $T>0$ are fixed and we omit the subscript/superscript $A$ in the whole proof.

We recall that $\boldsymbol{a}_{\lambda}, \boldsymbol{n}_{\lambda}$ and $\boldsymbol{m}_{\lambda}$ are defined in (2.2.1), (2.2.2) and (2.2.4). For $A>0$ and $i \in \mathbb{Z}$, we set as usual

$$
A_{\lambda}=\left\lfloor A \boldsymbol{n}_{\lambda}\right\rfloor, \quad I_{A}^{\lambda}=\llbracket-A_{\lambda}, A_{\lambda} \rrbracket, \quad i_{\lambda}=\left[i / \boldsymbol{n}_{\lambda},(i+1) / \boldsymbol{n}_{\lambda}\right) .
$$

For $[a, b]$ an interval of $[-A, A]$ and $\lambda \in(0,1)$, we introduce, assuming $-A<a<b<A$,

$$
\begin{cases}{[a, b]_{\lambda}} & =\llbracket\left\lfloor\boldsymbol{n}_{\lambda} a+\boldsymbol{m}_{\lambda}\right\rfloor+1,\left\lfloor\boldsymbol{n}_{\lambda} b-\boldsymbol{m}_{\lambda}\right\rfloor-1 \rrbracket \subset \mathbb{Z}  \tag{3.10.1}\\ {[-A, b]_{\lambda}} & =\llbracket-A_{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} b-\boldsymbol{m}_{\lambda}\right\rfloor-1 \rrbracket \subset \mathbb{Z} \\ {[a, A]_{\lambda}} & =\llbracket\left\lfloor\boldsymbol{n}_{\lambda} a+\boldsymbol{m}_{\lambda}\right\rfloor+1, A_{\lambda} \rrbracket \subset \mathbb{Z}\end{cases}
$$

For $x \in(-A, A)$ and $\lambda \in(0,1)$, we introduce as usual

$$
\begin{equation*}
x_{\lambda}=\left[\left[\left\lfloor\boldsymbol{n}_{\lambda} x-\boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\boldsymbol{n}_{\lambda} x+\boldsymbol{m}_{\lambda}\right\rfloor\right]\right] \subset \mathbb{Z} \tag{3.10.2}
\end{equation*}
$$

3.10.1. Speed of occupation. - We start with some easy estimates.

Lemma 3.10.1. - Consider a family of i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes $\left(N_{t}^{S}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. Let $a<b$.
(i) For $t<1, \lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\forall i \in \llbracket\left\lfloor a \boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor b \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket, N_{a_{\lambda} t}^{S}(i)>0\right]=0$.
(ii) For $t \geq 1, \lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\forall i \in \llbracket\left\lfloor a \boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor b \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket, N_{\boldsymbol{a}_{\lambda} t}^{S}(i)>0\right]=1$.
(iii) For $t<1$, $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\forall i \in \llbracket\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor,\left\lfloor b \boldsymbol{n}_{\lambda}\right\rfloor \rrbracket, N_{\boldsymbol{a}_{\lambda} t}^{S}(i)>0\right]=0$.
(iv) For $t>1$, $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\forall i \in \llbracket\left\lfloor a \boldsymbol{n}_{\lambda}\right\rfloor,\left\lfloor b \boldsymbol{n}_{\lambda}\right\rfloor \rrbracket, N_{\boldsymbol{a}_{\lambda} t}^{S}(i)>0\right]=1$.
(v) For $t>0$ and $i \in \mathbb{Z}, \lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[N_{a_{\lambda} t}^{S}(i)>0\right]=1$.

Proof. - To check points (i) and (ii), it suffices to note that

$$
\nu_{S}\left(\left(0, a_{\lambda} t\right)\right)^{(b-a) m_{\lambda}} \sim \mathrm{e}^{-(b-a) m_{\lambda} \nu_{S}\left(\left(a_{\lambda} t, \infty\right)\right)}
$$

which tends to 0 if $t<1$ (see (2.2.4)) and to 1 if $t \geq 1$ (because then $\boldsymbol{m}_{\lambda} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right) \leq$ $\left.\boldsymbol{m}_{\lambda} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right) \simeq \boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda} \rightarrow 0\right)$. To check points (iii) and (iv), observe that

$$
\nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda} t\right)\right)^{(b-a) \boldsymbol{n}_{\lambda}} \sim \mathrm{e}^{-(b-a) \boldsymbol{n}_{\lambda} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)} \sim \mathrm{e}^{-(b-a) \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right) / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)}
$$

tends to 0 if $t<1$ and to 1 if $t>1$ due to $\left(H_{S}(\infty)\right)$. Finally, (v) follows from the fact that $1-\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)$ obviously tends to 1 .
3.10.2. Height of the barriers. - We describe here the time needed for a destroyed (microscopic) cluster to be regenerated. Roughly, we assume that the zone around 0 is completely vacant at time $\boldsymbol{a}_{\lambda} t_{0}$. Then we consider the situation where a match falls on the site 0 at some time $\boldsymbol{a}_{\lambda} t_{1} \in\left(\boldsymbol{a}_{\lambda} t_{0}, \boldsymbol{a}_{\lambda}\left(t_{0}+1\right)\right)$ and we denote by $\Theta_{t_{0}, t_{1}}^{\lambda}$ the delay needed for the destroyed cluster to be fully regenerated (divided by $a_{\lambda}$ ). We show that

$$
\Theta_{t_{0}, t_{1}}^{\lambda} \simeq t_{1}-t_{0} \quad \text { when } \lambda \text { is small. }
$$

Lemma 3.10.2. - Consider a family of i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes $\left(N_{t}^{S}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. Let $0 \leq t_{0}<t_{1}<t_{0}+1$ be fixed. Put

$$
\begin{aligned}
& \zeta_{t_{0}, t}^{\lambda}(i)=\min \left(N_{a_{\lambda}\left(t_{0}+t\right)}^{S}(i)-N_{a_{\lambda} t_{0}}^{S}(i), 1\right), \\
& \zeta_{t_{1}, t}^{\lambda}(i)=\min \left(N_{a_{\lambda}\left(t_{1}+t\right)}^{S}(i)-N_{a_{\lambda} t_{1}}^{S}(i), 1\right)
\end{aligned}
$$

for all $t>0$ and $i \in \mathbb{Z}$. Define

$$
\Theta_{t_{0}, t_{1}}^{\lambda}=\inf \left\{t>0: \forall i \in C\left(\zeta_{t_{0}, t_{1}-t_{0}}^{\lambda}, 0\right), \zeta_{t_{1}, t}^{\lambda}(i)=1\right\} \in[0,1] .
$$

Then for all $\delta>0$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|\Theta_{t_{0}, t_{1}}^{\lambda}-\left(t_{1}-t_{0}\right)\right| \geq \delta\right]=0
$$

Proof. - We can assume that $t_{0}=0$ by stationarity. We put $u=t_{1}=t_{1}-t_{0}$. Exactly as in the case where $\beta=B S$ (see subsection 3.9.1), we obtain, for $h>0$,

$$
\operatorname{Pr}\left[\Theta_{t_{0}, t_{1}}^{\lambda} \leq h\right]=\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} u, \infty\right)\right)+\frac{\left[\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} u, \infty\right)\right)\right]^{2}}{\left[1-g_{S}^{\lambda}(u, h)\right]^{2}} g_{S}^{\lambda}(u, h),
$$

where

$$
g_{S}^{\lambda}(u, h)=\operatorname{Pr}\left[N_{a_{\lambda} u}^{S}(0)>0, N_{a_{\lambda}(u+h)}^{S}(0)>N_{a_{\lambda} u}^{S}(0)\right] .
$$

For $h>u$, we observe that $g_{S}^{\lambda}(u, h) \geq 1-\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} h, \infty\right)\right)-\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} u, \infty\right)\right)$, whence
$\operatorname{Pr}\left[\Theta_{t_{0}, t_{1}}^{\lambda} \leq h\right] \geq\left(\frac{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} u, \infty\right)\right)}{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} h, \infty\right)\right)+\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} u, \infty\right)\right)}\right)^{2}\left[1-\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} h, \infty\right)\right)-\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} u, \infty\right)\right)\right]$, which tends to 1 as $\lambda \rightarrow 0$ due to $\left(H_{S}(\infty)\right)$, since $\boldsymbol{a}_{\lambda}$ increases to infinity and since $h>u$.

For $h<u$, there holds $g_{S}^{\lambda}(u, h) \leq 1-\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} h, \infty\right)\right)$, so that

$$
\operatorname{Pr}\left[\Theta_{t_{0}, t_{1}}^{\lambda} \leq h\right] \leq \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} u, \infty\right)\right)+\left(\frac{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} u, \infty\right)\right)}{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} h, \infty\right)\right)}\right)^{2}\left[1-\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} h, \infty\right)\right)\right]
$$

which tends to 0 due to $\left(H_{S}(\infty)\right)$ and since $h<u$. This concludes the proof.
3.10.3. Persistent effect of microscopic fires. - We handle a study similar to subsection 3.9.2. Recall that $\mathcal{R}=\left(\varepsilon ; t_{0}, t_{1}, \ldots, t_{K} ; s\right)$ satisfies (PP) if
(i) $K \geq 2, \varepsilon \in\{-1,1\}$;
(ii) $0<t_{0}<t_{1}<\cdots<t_{K}<s<t_{K}+1$;
(iii) for all $k=0, \ldots, K-1, t_{k+1}-t_{k}<1$;
(iv) $t_{2}-t_{0}>1$ and for all $k=2, \ldots, K-2, t_{k+2}-t_{k}>1$,
and that we set $\varepsilon_{k}=(-1)^{k} \varepsilon$ for $k \geq 0$.
For a family of i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes $\left(N_{t}^{S}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$, we introduce, for each $\lambda$ in $(0,1)$, the process $\left(\zeta_{t}^{\lambda, \mathcal{R}}(i)\right)_{t \geq t_{0}, i \in \llbracket-m_{\lambda}, m_{\lambda} \rrbracket}$ defined as follows:
$\triangleright$ for all $t \in\left[t_{0}, t_{1}\right)$, all $i \in \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket, \zeta_{t}^{\lambda, \mathcal{R}}(i)=\min \left(N_{\boldsymbol{a}_{\lambda} t}^{S}(i)-N_{\boldsymbol{a}_{\lambda} t_{0}}^{S}(i), 1\right)$,
$\triangleright$ for all $i \in \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket, \zeta_{t_{1}}^{\lambda, \mathcal{R}}(i)=\zeta_{t_{1}-}^{\lambda, \mathcal{R}}(i) \mathbb{1}_{\left\{i \notin C\left(\zeta_{t_{1}-}^{\lambda, \mathcal{R}}, 0\right)\right\}}$,
$\triangleright$ for $k=1, \ldots, K-1$,
$\left.{ }^{*}\right)$ for all $t \in\left(t_{k}, t_{k+1}\right), i \in \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket$,

$$
\zeta_{t}^{\lambda, \mathcal{R}}(i)=\min \left(\zeta_{t_{k}}^{\lambda, \mathcal{R}}(i)+N_{a_{\lambda} t}^{S}(i)-N_{a_{\lambda} t_{k}}^{S}(i), 1\right),
$$

(*) for all $i \in \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket$,

$$
\zeta_{t_{k+1}}^{\lambda, \mathcal{R}}(i)=\zeta_{t_{k+1}-}^{\lambda, \mathcal{R}}(i) \mathbb{1}_{i \notin C\left(\zeta_{t_{k+1}}^{\lambda, \mathcal{R}}, \epsilon_{k} m_{\lambda}\right)} ;
$$

$\triangleright$ for all $t \in\left(t_{K}, \infty\right), i \in \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket$,

$$
\zeta_{t}^{\lambda, \mathcal{R}}(i)=\min \left(\zeta_{t_{K}}^{\lambda, \mathcal{R}}(i)+N_{a_{\lambda} t}^{S}(i)-N_{a_{\lambda} t_{K}}^{S}(i), 1\right)
$$

Consider the event
$\Omega_{\mathcal{R}}^{S}(\lambda)=\left\{\exists-\boldsymbol{m}_{\lambda}<i_{1}<i_{2}<i_{3}<\boldsymbol{m}_{\lambda}: \zeta_{s}^{\lambda, \mathcal{R}}\left(i_{1}\right)=\zeta_{s}^{\lambda, \mathcal{R}}\left(i_{3}\right)=0, \zeta_{s}^{\lambda, \mathcal{R}}\left(i_{2}\right)=1\right\}$.
Lemma 3.10.3. - Let $\mathcal{R}=\left(\varepsilon ; t_{0}, t_{1}, \ldots, t_{K} ; s\right)$ satisfy $(\mathrm{PP})$. For each $\lambda \in(0,1]$, consider the process $\left(\zeta_{t}^{\lambda, \mathcal{R}}(i)\right)_{t \geq t_{0}, i \in \llbracket-m_{\lambda}, m_{\lambda} \rrbracket}$ defined above. If $t_{2}-t_{1}<t_{1}-t_{0}$, there holds

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\Omega_{\mathcal{R}}^{S}(\lambda)\right)=1
$$

Compare to Lemma 3.9.2: the condition $\Theta_{t_{0}, t_{1}}>t_{2}-t_{1}$ is replaced by the condition $t_{1}-t_{0}>t_{2}-t_{1}$. This is very natural, in view of Lemma 3.10.2.

Proof. - In view of Lemma 3.10.1, the proof is very similar to that of Lemma 3.9.2. We assume that $\varepsilon=1$ and that $K$ is even for simplicity. Fix $\alpha=1 / K$.

First fire. - We put $C=C\left(\zeta_{t_{1}-}^{\lambda, \mathcal{R}}, 0\right)$. Since $t_{1}-t_{0}<1, C \subset \llbracket-\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$ with probability tending to 1 (use Lemma 3.10.1(i) and space/time stationarity). Thus the match falling at time $t_{1}$ destroys nothing outside $\llbracket-\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$.

Second fire. - Since $t_{2}-t_{0}>1$, at least one seed has fallen, during $\left[t_{0}, t_{2}\right)$ on each site of $\llbracket\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor+1, \boldsymbol{m}_{\lambda} \rrbracket$ with probability tending to 1 (use Lemma 3.10 .1 (ii) and space/time stationarity). Thus the fire at time $t_{2}$ destroys completely the zone $\llbracket\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor+1, \boldsymbol{m}_{\lambda} \rrbracket$. Furthermore, it does not affect $\llbracket-\boldsymbol{m}_{\lambda},-\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor-1 \rrbracket$ with probability tending to 1 , because $t_{2}<t_{1}+\Theta_{t_{0}, t_{1}}^{\lambda}$ with probability tending to $1\left(\Theta_{t_{0}, t_{1}}^{\lambda} \simeq t_{1}-t_{0}\right.$ by Lemma 3.10.2 and $t_{2}-t_{1}<t_{1}-t_{0}$ by assumption) and because there is an empty site in $C \subset \llbracket-\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$ during $\left[t_{1}, t_{1}+\Theta_{t_{0}, t_{1}}^{\lambda}\right]$ (by definition of $\Theta_{t_{0}, t_{1}}^{\lambda}$ ).

Third fire. - Since $t_{3}-t_{2}<1$, the probability that there is a vacant site in $\llbracket\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor+1,\left\lfloor 2 \alpha \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$ at time $t_{3}$ tends to 1 as $\lambda \rightarrow 0$ (use Lemma 3.10.1 (i) and space/time stationarity).

Next, all the sites of $\llbracket-\boldsymbol{m}_{\lambda},-\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor-1 \rrbracket$ are occupied at time $t_{3}-$ with probability tending to 1 (because they have not been affected by a fire during $\left[t_{0}, t_{3}\right.$ ) and because $t_{3}-t_{0}>t_{2}-t_{0}>1$, see Lemma 3.10.1 (ii)). Thus the fire at time $t_{3}$ destroys the zone $\llbracket-\boldsymbol{m}_{\lambda},-\left\lfloor\alpha \boldsymbol{m}_{\lambda}\right\rfloor-1 \rrbracket$ and does not affect the zone $\llbracket\left\lfloor 2 \alpha \boldsymbol{m}_{\lambda}\right\rfloor, \boldsymbol{m}_{\lambda} \rrbracket$.

Last fire and conclusion. - Iterating the procedure, we see that with a probability tending to 1 as $\lambda \rightarrow 0$, the fire at time $t_{K}$ destroys the zone

$$
\left[\left[\left\lfloor\left(\frac{1}{2} K \alpha\right) \boldsymbol{m}_{\lambda}\right\rfloor, \boldsymbol{m}_{\lambda}\right]\right]=\left[\left[\left\lfloor\frac{1}{2} \boldsymbol{m}_{\lambda}\right\rfloor, \boldsymbol{m}_{\lambda}\right]\right] .
$$

Then one easily concludes: since $0<s-t_{K}<1$, the probability that there is at least one site in $\llbracket\left\lfloor\frac{1}{2} \boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\frac{2}{3} \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$ with no seed falling during $\left[t_{K}, s\right]$ tends to 1 (by Lemma 3.10.1 (i)), the probability that there is at least one site in $\llbracket\left\lfloor\frac{2}{3} \boldsymbol{m}_{\lambda}\right\rfloor+1,\left\lfloor\frac{5}{6} \boldsymbol{m}_{\lambda}\right\rfloor \rrbracket$ with at least one seed falling during $\left[t_{K}, s\right]$ tends to 1 (by Lemma 3.10.1 (v)), and the probability that there is at least one site in $\llbracket\left\lfloor\frac{5}{6} \boldsymbol{m}_{\lambda}\right\rfloor+1, \boldsymbol{m}_{\lambda} \rrbracket$ with no seed falling during $\left[t_{K}, s\right]$ tends to 1 (by Lemma 3.10.1 (i)).
3.10.4. The coupling. - We are going to construct a coupling between the $\mathrm{FF}_{A}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process (on the time interval $\left[0, \boldsymbol{a}_{\lambda} T\right]$ ) and the $\mathrm{LFF}_{A}(\infty)$-process (on $[0, T]$ ).

First, we couple a family of i.i.d. $\operatorname{SR}\left(\mu_{M}^{\lambda}\right)$-processes $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ with a Poisson measure $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)$ on $[0, T] \times[-A, A]$ with intensity measure $\mathrm{d} t \mathrm{~d} x$ as in Proposition 3.2.1.

We call $n:=\pi_{M}([0, T] \times[-A, A])$ and we consider the marks $\left(T_{q}, X_{q}\right)_{q=1, \ldots, n}$ of $\pi_{M}$ ordered in such a way that $0<T_{1}<\cdots<T_{n}<T$.

Next, we introduce some i.i.d. families of i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes $\left(N_{t}^{S, q}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$, for $q=0,1, \ldots$, independent of $\pi_{M}$ and $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$.

Then we build a family of i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes (independent of $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ and $\pi_{M}$ ) as follows.
$\triangleright$ For $q \in\{1, \ldots, n\}$, recall that $\left.\left(X_{q}\right)_{\lambda}=\llbracket\left\lfloor\boldsymbol{n}_{\lambda} X_{q}-\boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\boldsymbol{n}_{\lambda} X_{q}+\boldsymbol{m}_{\lambda}\right\rfloor \rrbracket\right)$, and for all $i \in\left(X_{q}\right)_{\lambda}$, set

$$
\left(N_{t}^{S, \lambda}(i)\right)_{t \geq 0}=\left(N_{t}^{S, q}\left(i-\left\lfloor\boldsymbol{n}_{\lambda} X_{q}\right\rfloor\right)\right)_{t \geq 0}
$$

(In the rare case where $i$ belongs to $\left(X_{q}\right)_{\lambda} \cap\left(X_{r}\right)_{\lambda}$ for some $q<r$, set e.g. $\left(N_{t}^{S, \lambda}(i)\right)_{t \geq 0}=\left(N_{t}^{S, q}\left(i-\left\lfloor\boldsymbol{n}_{\lambda} X_{q}\right\rfloor\right)\right)_{t \geq 0}$. This will occur with a very small probability, so that this choice is not important).
$\triangleright$ For all other $i \in \mathbb{Z}$ set

$$
\left(N_{t}^{S, \lambda}(i)\right)_{t \geq 0}=\left(N_{t}^{S, 0}(i)\right)_{t \geq 0}
$$

The $\mathrm{FF}_{A}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in I_{A}^{\lambda}}$ is built from the seed processes $\left(N_{t}^{S, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ and from the match processes $\left(N_{t}^{M, \lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$.

Finally, we build the $\mathrm{LFF}_{A}(\infty)$-process $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \in[0, T], x \in[-A, A]}$ from $\pi_{M}$ (use Algorithm 3.9.3 replacing $\Theta_{T_{k+1}-Z_{T_{k+1}-}\left(X_{k+1}\right), T_{k+1}}^{k+1}$ by $Z_{T_{k+1}-}\left(X_{k+1}\right)$ ) and observe that it is independent of $\left(N_{t}^{S, q}(i)\right)_{t \in[0, T], i \in \mathbb{Z}, q \geq 0}$.
3.10.5. A favorable event. - First, we know from Proposition 3.2.1 that

$$
\Omega_{A, T}^{M}(\lambda):=\left\{\forall t \in[0, T], \forall i \in I_{A}^{\lambda}, \Delta N_{a_{\lambda} t}^{M, \lambda}(i) \neq 0 \text { iff } \pi_{M}\left(\{t\} \times i_{\lambda}\right) \neq 0\right\}
$$

satisfies $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\Omega_{A, T}^{M}(\lambda)\right]=1$. Next, we recall that the marks of $\pi_{M}$ are called $\left(T_{1}, X_{1}\right), \ldots,\left(T_{n}, X_{n}\right)$ and are ordered chronologically. We introduce

$$
\mathcal{T}_{M}=\left\{0, T_{1}, \ldots, T_{n}\right\}, \quad \mathcal{B}_{M}=\left\{X_{1}, \ldots, X_{n}\right\}
$$

as well as the set $\mathcal{C}_{M}$ of connected components of $[-A, A] \backslash \mathcal{B}_{M}$ (sometimes referred to as cells). We also introduce

$$
\mathcal{S}_{M}=\left\{2 t-s: s, t \in \mathcal{T}_{M}, s<t\right\},
$$

which has to be seen as the possible limit values of $t+\Theta_{s, t}^{\lambda} \simeq t+t-s$, recall Lemma 3.10.2.

For $\alpha>0$, we consider the event

$$
\Omega_{M}(\alpha)=\left\{\min _{\substack{s, t \in \mathcal{T}_{M} \cup \mathcal{S}_{M} \\ s \neq t}}|t-s| \geq \alpha, \min _{\substack{s, t \in \mathcal{T}_{M} \cup \mathcal{S}_{M} \\ s \neq t}}|t-(s+1)| \geq \alpha, \min _{\substack{x, y \in \mathcal{B}_{M} \cup\{-A, A\} \\ x \neq y}}|x-y| \geq \alpha\right\},
$$

which clearly satisfies $\lim _{\alpha \rightarrow 0} \operatorname{Pr}\left[\Omega_{M}(\alpha)\right]=1$. As in the case $\beta=B S$, for any given $\alpha>0$, there is $\lambda_{\alpha}>0$ such that for all $\lambda \in\left(0, \lambda_{\alpha}\right)$, on $\Omega_{M}(\alpha)$,
$\triangleright$ for all $x, y \in \mathcal{B}_{M} \cup\{-A, A\}$, with $x \neq y, x_{\lambda} \cap y_{\lambda}=\varnothing$;
$\triangleright$ the family $\left\{c_{\lambda}, c \in \mathcal{C}_{M}\right\} \cup\left\{x_{\lambda}, x \in \mathcal{B}_{M}\right\}$ is a partition of $I_{A}^{\lambda}$ (recall (3.10.1) and (3.10.2)).

Let $q \in\{1, \ldots, n\}$. We call $\mathcal{U}_{q}$ the set of all possible $\mathcal{R}=\left(\varepsilon, t_{0}, \ldots, t_{K} ; s\right)$ satisfying $(\mathrm{PP})$ with $\varepsilon \in\{-1,1\}$, with $\left\{t_{0}, \ldots, t_{K}, s\right\} \subset \mathcal{T}_{M}$ and with $t_{1}-t_{0}>t_{2}-t_{1}$. We introduce, for $q=1, \ldots, n$ and $\mathcal{R} \in \mathcal{U}_{q}$, the event $\Omega_{\mathcal{R}}^{S, q}(\lambda)$ defined as in subsection 3.10.3 with the $\operatorname{SR}\left(\mu_{S}\right)$-processes $\left(N_{t}^{S, q}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. Then we put

$$
\Omega_{1}^{S}(\lambda)=\bigcap_{q=1}^{n} \bigcap_{\mathcal{R} \in \mathcal{U}_{q}} \Omega_{\mathcal{R}}^{S, q}(\lambda)
$$

which satisfies $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\Omega_{1}^{S}(\lambda)\right)=1$ thanks to Lemma 3.10.3.
We also consider the event $\Omega_{2}^{S}(\lambda)$ on which the following conditions hold: for all $t_{1}, t_{2} \in \mathcal{T}_{M} \cup \mathcal{S}_{M}$ with $0<t_{2}-t_{1}<1$, for all $q=1, \ldots, n$, there are

$$
-\boldsymbol{m}_{\lambda}<i_{1}<i_{2}<-\frac{1}{2} \boldsymbol{m}_{\lambda}<i_{3}<0<i_{4}<\frac{1}{2} \boldsymbol{m}_{\lambda}<i_{5}<i_{6}<\boldsymbol{m}_{\lambda}
$$

such that

$$
\begin{aligned}
& \triangleright \text { for } j=1,3,4,6, N_{a_{\lambda} t_{2}}^{S, q}\left(i_{j}\right)-N_{a_{\lambda} t_{1}}^{S, q}\left(i_{j}\right)=0, \\
& \triangleright \text { for } j=2,5, N_{a_{\lambda} t_{2}}^{S, q}\left(i_{j}\right)-N_{a_{\lambda} t_{1}}^{S, q}\left(i_{j}\right)>0 .
\end{aligned}
$$

There holds $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\Omega_{2}^{S}(\lambda)\right)=1$. Indeed, it suffices to prove that almost surely, $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\Omega_{2}^{S}(\lambda) \mid \pi_{M}\right)=1$. Since there are a.s. finitely many possibilities for $q, t_{1}, t_{2}$ and since $\pi_{M}$ is independent of $\left(N_{t}^{S, q}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$, it suffices to work with a fixed $q$ in $\{1, \ldots, n\}$ and some fixed $0<t_{2}-t_{1}<1$. The result then follows from Lemma 3.10.1 (i)-(v) together with space/time stationarity.

Next we introduce the event $\Omega_{3}^{S}(\lambda)$ on which the following conditions hold: for all $t_{1}, t_{2} \in \mathcal{T}_{M} \cup \mathcal{S}_{M}$,
$\triangleright$ for all $c \in \mathcal{C}_{M}$, if $0<t_{2}-t_{1}<1$, there is $i \in c_{\lambda}$ with $N_{a_{\lambda} t_{2}}^{S, \lambda}(i)-N_{a_{\lambda} t_{1}}^{S, \lambda}(i)=0$;
$\triangleright$ for all $x \in \mathcal{B}_{M}$, if $0<t_{2}-t_{1}<1$, there is $i \in x_{\lambda}$ with $N_{a_{\lambda} t_{2}}^{S, \lambda}(i)-N_{a_{\lambda} t_{1}}^{S, \lambda}(i)=0$;
$\triangleright$ if $t_{2}-t_{1}>1$, for all $c \in \mathcal{C}_{M}$, for all $i \in c_{\lambda}, N_{a_{\lambda} t_{2}}^{S, \lambda}(i)-N_{a_{\lambda} t_{1}}^{S, \lambda}(i)>0$;
$\triangleright$ if $t_{2}-t_{1}>1$, for all $x \in \mathcal{B}_{M}$, for all $i \in x_{\lambda}, N_{a_{\lambda} t_{2}}^{S, \lambda}(i)-N_{a_{\lambda} t_{1}}^{S, \lambda}(i)>0$.
There holds $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\Omega_{3}^{S}(\lambda)\right)=1$. As previously, it suffices to work with some fixed $t_{1}, t_{2}, x \in(-A, A)$ and $c=(a, b) \subset(-A, A)$. Observing that $\left|x_{\lambda}\right| \sim 2 m_{\lambda}$ and that $\left|c_{\lambda}\right| \sim(b-a) \boldsymbol{n}_{\lambda}$, Lemma 3.10.1 and space/time stationarity shows the result.

We also need $\Omega_{4}^{S}(\gamma, \lambda)$, defined for $\gamma>0$ as follows: for all $q=1, \ldots, n$, for all $t_{0}, t_{1} \in \mathcal{T}_{M}$ with $t_{0}<t_{1}<t_{0}+1$, there holds $\left|\Theta_{t_{0}, t_{1}}^{q, \lambda}-\left(t_{1}-t_{0}\right)\right|<\gamma$. Here $\Theta_{t_{0}, t_{1}}^{q, \lambda}$ is defined as in Lemma 3.10.2 with the seed processes family $\left(N_{t}^{S, q}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. Lemma 3.10.2 directly implies that for any $\gamma>0, \lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\Omega_{4}^{S}(\gamma, \lambda)\right]=1$.

We finally introduce the event

$$
\Omega(\alpha, \gamma, \lambda)=\Omega_{A, T}^{M}(\lambda) \cap \Omega_{M}(\alpha) \cap \Omega_{1}^{S}(\lambda) \cap \Omega_{2}^{S}(\lambda) \cap \Omega_{3}^{S}(\lambda) \cap \Omega_{4}^{S}(\gamma, \lambda)
$$

We have shown that for any $\varepsilon>0$, there exists $\alpha>0$ such that for any $\gamma>0$, there holds $\liminf _{\lambda \rightarrow 0} \operatorname{Pr}[\Omega(\alpha, \gamma, \lambda)]>1-\varepsilon$.
3.10.6. Heart of the proof. - We now handle the main part of the proof, following closely subsection 3.9.5.

Consider the $\mathrm{LFF}_{A}(\infty)$-process. Observe that by construction, we have, for $c \in \mathcal{C}_{M}$ and $x, y \in c, Z_{t}(x)=Z_{t}(y)$ for all $t \in[0, T]$, thus we can introduce $Z_{t}(c)$.

If $x \in \mathcal{B}_{M}$, it is at the boundary of two cells $c_{-}, c_{+} \in \mathcal{C}_{M}$ and then we set $Z_{t}\left(x_{-}\right)=$ $Z_{t}\left(c_{-}\right)$and $Z_{t}\left(x_{+}\right)=Z_{t}\left(c_{+}\right)$for all $t \in[0, T]$.

If $x \in(-A, A) \backslash \mathcal{B}_{M}$, we put $Z_{t}\left(x_{-}\right)=Z_{t}\left(x_{+}\right)=Z_{t}(x)$ for all $t \in[0, T]$.
For $x \in \mathcal{B}_{M}$ and $t \geq 0$ we set $\widetilde{H}_{t}(x)=\max \left(H_{t}(x), 1-Z_{t}(x), 1-Z_{t}\left(x_{-}\right), 1-Z_{t}\left(x_{+}\right)\right)$.
Actually $Z_{t}(x)$ always equals either $Z_{t}\left(x_{-}\right)$or $Z_{t}\left(x_{+}\right)$and these can be distinct only at a point where has occurred a microscopic fire (that is if $x=X_{q}$ for some $q \in\{1, \ldots, n\}$ with $T_{q}<t$ and $\left.Z_{T_{q}-}\left(X_{q}\right)<1\right)$.

For all $x \in(-A, A)$ and $t \in[0, T]$, we put

$$
\tau_{t}(x)=\sup \left\{s \leq t: Z_{s}\left(x_{+}\right)=Z_{s}\left(x_{-}\right)=Z_{s}(x)=0\right\} \in[0, t] \cap \mathcal{T}_{M}
$$

For $c \in \mathcal{C}_{M}$ and $t \in[0, T]$, we can define $\tau_{t}(c)$ as usual.
Observe, using Algorithm 3.9.3, that as when $\beta=B S$,

$$
\begin{align*}
& \text { for } x \notin \mathcal{B}_{M}, \quad Z_{t}(x)=\min \left(t-\tau_{t}(x), 1\right) \text { for all } t \in[0, T]  \tag{3.10.3}\\
& \text { for } q=1, \ldots, n, \quad Z_{t}\left(X_{q}\right)=\min \left(t-\tau_{t}\left(X_{q}\right), 1\right) \text { for all } t \in\left[0, T_{q}\right) \tag{3.10.4}
\end{align*}
$$

We also define for all $t \in[0, T]$, all $c \in \mathcal{C}_{M}$ and all $x \in(-A, A)$

$$
\begin{aligned}
\tau_{t}^{\lambda}(c) & =\sup \left\{s \leq t: \forall i \in c_{\lambda}, \eta_{a_{\lambda} t-}^{\lambda}(i)=1 \text { and } \eta_{a_{\lambda} t}^{\lambda}(i)=0\right\} \in[0, t], \\
\rho_{t}^{\lambda}(c) & =\sup \left\{s \leq t: \exists i \in c_{\lambda}, \eta_{a_{\lambda} t-}^{\lambda}(i)=1 \text { and } \eta_{a_{\lambda} t}^{\lambda}(i)=0\right\} \in[0, t], \\
\tau_{t}^{\lambda}(x) & =\sup \left\{s \leq t: \forall i \in x_{\lambda}, \eta_{a_{\lambda} t-}^{\lambda}(i)=1 \text { and } \eta_{a_{\lambda} t}^{\lambda}(i)=0\right\} \in[0, t]
\end{aligned}
$$

with the convention that $\eta_{0-}^{\lambda}(i)=1$ for all $i \in I_{A}^{\lambda}$. Observe that on $\Omega_{A, T}^{M}(\lambda)$, we have $\tau_{t}^{\lambda}(c), \rho_{t}^{\lambda}(c), \tau_{t}^{\lambda}(x) \in[0, t] \cap \mathcal{T}_{M}$ for all $t \in[0, T]$, all $c \in \mathcal{C}_{M}$ and all $x \in(-A, A)$.

For $t \in[0, T]$, consider the event

$$
\Omega_{t}^{\lambda}=\left\{\forall s \in[0, t], \forall c \in \mathcal{C}_{M}, \tau_{s}^{\lambda}(c)=\rho_{s}^{\lambda}(c)=\tau_{s}(c) \text { and } \forall x \in \mathcal{B}_{M}, \tau_{s}^{\lambda}(x)=\tau_{s}(x)\right\}
$$

Lemma 3.10.4. - Let $\alpha>\gamma>0$. For any $\lambda \in\left(0, \lambda_{\alpha}\right)$, $\Omega_{T}^{\lambda}$ a.s. holds on $\Omega(\alpha, \gamma, \lambda)$.

Proof. - We work on $\Omega(\alpha, \gamma, \lambda)$ and assume that $\lambda \in\left(0, \lambda_{\alpha}\right)$. Clearly,

$$
\tau_{0}(x)=\tau_{0}^{\lambda}(x)=0 \quad \text { and } \quad \tau_{0}(c)=\tau_{0}^{\lambda}(c)=\rho_{0}^{\lambda}(c)=0
$$

for all $x \in \mathcal{B}_{M}$, all $c \in \mathcal{C}_{M}$, so that $\Omega_{0}^{\lambda}$ a.s. holds. We will show that for $q=0, \ldots, n-1$, $\Omega_{T_{q}}^{\lambda}$ implies $\Omega_{T_{q+1}}^{\lambda}$. This will prove that $\Omega_{T_{n}}^{\lambda}$ holds. The extension to $\Omega_{T}^{\lambda}$ will be straightforward (see step 1 below).

We thus fix $q \in\{0, \ldots, n-1\}$ and assume $\Omega_{T_{q}}^{\lambda}$. We repeatedly use below that on the time interval $\left(T_{q}, T_{q+1}\right)$, there are no fires at all (in $[-A, A]$ ) for the $\operatorname{LFF}_{A}(B S)$ process and no fires at all (in $\left.I_{A}^{\lambda}\right)$ during $\left(\boldsymbol{a}_{\lambda} T_{q}, \boldsymbol{a}_{\lambda} T_{q+1}\right)$ for the $\mathrm{FF}_{A}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process (use $\Omega_{A, T}^{M}(\lambda)$ ).

Step 1. - Exactly as in the proof of Lemma 3.9.5, step $1, \Omega_{T_{q}}^{\lambda}$ implies $\Omega_{T_{q+1}-}^{\lambda}$.
Step 2. - Exactly as in the proof of Lemma 3.9.5, step 2, we observe that for $c \in \mathcal{C}_{M}$, on $\Omega_{T_{q+1}-}^{\lambda}$, there holds, for all $i \in c_{\lambda}$,

$$
\begin{equation*}
\eta_{a_{\lambda} T_{q+1}-}^{\lambda}(i)=\min \left(N_{a_{\lambda} T_{q+1}-}^{S, 0}(i)-N_{a_{\lambda} \tau_{T_{q}}(c)}^{S, 0}(i), 1\right) \tag{3.10.5}
\end{equation*}
$$

Step 3. - If $Z_{T_{q+1}-}\left(X_{q+1}\right)<1$, there exist $j_{1}, j_{2}, j_{3}, j_{4} \in\left(X_{q+1}\right)_{\lambda}$ such that

$$
\begin{gathered}
j_{1}<j_{2}<\left\lfloor\boldsymbol{n}_{\lambda} X_{q+1}\right\rfloor<j_{3}<j_{4}, \\
\eta_{a_{\lambda} T_{q+1}-}^{\lambda}\left(j_{2}\right)=\eta_{a_{\lambda} T_{q+1}-}^{\lambda}\left(j_{3}\right)=0, \\
\eta_{a_{\lambda} T_{q+1}-}^{\lambda}\left(j_{1}\right)=\eta_{a_{\lambda} T_{q+1}-}^{\lambda}\left(j_{4}\right)=1 .
\end{gathered}
$$

The proof is the same as Lemma 3.9.5, step 3.
Step 4. - Next we check that if $Z_{T_{q+1}-}(c)=1$ for some $c \in \mathcal{C}_{M}$, then

$$
\eta_{a_{\lambda} T_{q+1}-}^{\lambda}(i)=1 \quad \text { for all } i \in c_{\lambda} .
$$

Recalling (3.10.3), we see that $Z_{T_{q+1}-}(c)=1$ implies that $T_{q+1}-\tau_{T_{q+1}-}(c) \geq 1$ and thus $T_{q+1}-\tau_{T_{q}}(c) \geq 1$ by step 1 . Using $\Omega_{M}(\alpha)$ and that $T_{q+1}, \tau_{T_{q}}(c) \in \mathcal{T}_{M}$, we deduce that $T_{q+1}-\tau_{T_{q}}(c)>1$. Using (3.10.5), we conclude that for all $i \in c_{\lambda}$,

$$
\eta_{a_{\lambda} T_{q+1}-}^{\lambda}(i)=\min \left(N_{a_{\lambda} T_{q+1}-}^{S, 0}(i)-N_{a_{\lambda} \tau_{T_{q}}(c)(i)}^{S, 0}, 1\right)=1
$$

by $\Omega_{3}^{S}(\lambda)$.
Step 5. - We now prove that if $\widetilde{H}_{T_{q+1}-}(x)=0$ for some $x \in \mathcal{B}_{M}$, then

$$
\eta_{a_{\lambda} T_{q+1}-}^{\lambda}(i)=1 \quad \text { for all } i \in x_{\lambda} .
$$

Preliminary considerations. - Let $k \in\{1, \ldots, n\}$ such that $x=X_{k}$, which is at the boundary of two cells $c_{-}, c_{+} \in \mathcal{C}_{M}$. We know that $\widetilde{H}_{T_{q+1}-}(x)=0$, whence $H_{T_{q+1}-}(x)=0$ and $Z_{T_{q+1}-}(x)=Z_{T_{q+1}-}\left(c_{+}\right)=Z_{T_{q+1}-}\left(c_{-}\right)=1$. This implies that $T_{q+1} \geq 1$ (because $Z_{t}(x)=t$ for all $t<1$ and all $x \in[-A, A]$ ) and thus $T_{q+1} \geq 1+\alpha$ due to $\Omega_{M}(\alpha)$.

No fire has concerned $\left(c_{-}\right)_{\lambda}$ during $\left(\boldsymbol{a}_{\lambda} \rho_{T_{q+1}-}^{\lambda}\left(c_{-}\right), \boldsymbol{a}_{\lambda} T_{q+1}\right)$ (by definition of $\left.\rho_{T_{q+1}-}^{\lambda}\left(c_{-}\right)\right)$. But step 1 implies that $\rho_{T_{q+1}-}^{\lambda}\left(c_{-}\right)=\tau_{T_{q+1}-}\left(c_{-}\right) \leq T_{q+1}-1$ because $Z_{T_{q+1}-}\left(c_{-}\right)=1$, see (3.10.3). Recalling $\Omega_{M}(\alpha)$, we deduce that

$$
\rho_{T_{q+1}-}^{\lambda}\left(c_{-}\right)<T_{q+1}-1-\alpha .
$$

Using a similar argument for $c_{+}$, we conclude that no match falling outside $\left(X_{k}\right)_{\lambda}$ can affect $\left(X_{k}\right)_{\lambda}$ during $\left(\boldsymbol{a}_{\lambda}\left(T_{q+1}-1-\alpha\right), \boldsymbol{a}_{\lambda} T_{q+1}\right)$ (because to affect $\left(X_{k}\right)_{\lambda}$, a match falling outside $\left(X_{k}\right)_{\lambda}$ needs to cross $c_{-}$or $\left.c_{+}\right)$.

Case 1. - First assume that $k \geq q+1$. Then we know that no fire has fallen on $\left(X_{k}\right)_{\lambda}$ during $\left[0, \boldsymbol{a}_{\lambda} T_{q+1}\right)$. Due to the preliminary considerations, we deduce that no fire at all has concerned $\left(X_{k}\right)_{\lambda}$ during $\left(\boldsymbol{a}_{\lambda}\left(T_{q+1}-1-\alpha\right), \boldsymbol{a}_{\lambda} T_{q+1}\right)$. Using $\Omega_{3}^{S}(\lambda)$, we conclude that $\left(X_{k}\right)_{\lambda}$ is completely occupied at time $a_{\lambda} T_{q+1}-$.
Case 2. - Assume that $k \leq q$ and $Z_{T_{k}-}\left(X_{k}\right)=1$, so that there already has been a macroscopic fire in $\left(X_{k}\right)_{\lambda}$ (at time $\left.\boldsymbol{a}_{\lambda} T_{k}\right)$. Since $Z_{T_{k}}\left(X_{k}\right)=0$ and $Z_{T_{q+1}-}\left(X_{k}\right)=1$, we deduce that $T_{q+1}-T_{k} \geq 1$, whence $T_{q+1}-T_{k} \geq 1+\alpha$ as usual. We conclude as in Case 1 that no fire at all has concerned $\left(X_{k}\right)_{\lambda}$ during $\left(T_{S}\left(T_{q+1}-1-\alpha\right), T_{S} T_{q+1}\right)$, which implies the claim by $\Omega_{3}^{S}(\lambda)$.
Case 3. - Assume that $k \leq q$ and $Z_{T_{k}-}\left(X_{k}\right)<1$ and $T_{q+1}-T_{k} \geq 1$, whence $T_{q+1}-T_{k} \geq 1+\alpha$ due to $\Omega_{M}(\alpha)$. Then there already has been a microscopic fire in $\left(X_{k}\right)_{\lambda}$ (at time $\left.\boldsymbol{a}_{\lambda} T_{k}\right)$. But there are no fire in $\left(X_{k}\right)_{\lambda}$ during $\left(\boldsymbol{a}_{\lambda} T_{k}, \boldsymbol{a}_{\lambda} T_{q+1}\right) \supset$ $\left(T_{S}\left(T_{q+1}-1-\alpha\right), T_{S} T_{q+1}\right)$ and we conclude as in case 2.
Case 4. - Assume finally that $k \leq q$ and $Z_{T_{k}-}\left(X_{k}\right)<1$ and $T_{q+1}-T_{k}<1$, whence $T_{q+1}-T_{k} \leq 1-\alpha$ due to $\Omega_{M}(\alpha)$. There has been a microscopic fire in $\left(X_{k}\right)_{\lambda}$ (at time $\boldsymbol{a}_{\lambda} T_{k}$ ). Since $H_{T_{q+1}-}\left(X_{k}\right)=0$, we deduce (see Algorithm 3.9.3 and recall that $\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}^{k}$ is replaced by $\left.Z_{T_{k}-}\left(X_{k}\right)\right)$ that $T_{k}+Z_{T_{k}-}\left(X_{k}\right) \leq T_{q+1}$, whence $T_{k}+Z_{T_{k}-}\left(X_{k}\right) \leq T_{q+1}-\alpha$ by $\Omega_{M}(\alpha)\left(\mathcal{S}_{M}\right.$ was designed for that purpose).
Consider the zone $C=C\left(\eta_{a_{\lambda} T_{k}-}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} X_{k}\right\rfloor\right)$ destroyed by the match falling at time $\boldsymbol{a}_{\lambda} T_{k}$. This zone is completely occupied at time $\boldsymbol{a}_{\lambda}\left(T_{k}+\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}^{k, \lambda}\right)$ : this follows from the definition of $\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}^{k, \lambda}$, see Lemma 3.9.1 and from the preliminary considerations. Using $\Omega_{4}^{S}(\gamma, \lambda)$, we deduce that

$$
T_{k}+\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}^{k, \lambda} \leq T_{k}+Z_{T_{k}-}\left(X_{k}\right)+\gamma<T_{q+1}
$$

since $\gamma<\alpha$. Hence $C$ is completely occupied at time $\boldsymbol{a}_{\lambda} T_{q+1}-$.
Consider now $i \in\left(X_{k}\right)_{\lambda} \backslash C$. Then $i$ has not been killed by the fire starting at $\left\lfloor\boldsymbol{n}_{\lambda} X_{k}\right\rfloor$. Thus $i$ cannot have been killed during ( $\boldsymbol{a}_{\lambda}\left(T_{q+1}-1-\alpha\right), \boldsymbol{a}_{\lambda} T_{q+1}$ ) (due to the preliminary considerations) and we conclude, using $\Omega_{3}^{S}(\lambda)$, that $i$ is occupied at time $a_{\lambda} T_{q+1}-$. This implies the claim.

Step 6. - Let us now prove that if $\widetilde{H}_{T_{q+1}-}(x)>0$ and $Z_{T_{q+1}-}\left(x_{+}\right)=1$ for some $x \in \mathcal{B}_{M}$, there are $i_{1}, i_{2} \in x_{\lambda}$ such that $i_{1}<i_{2}$ and $\eta_{a_{\lambda} T_{q+1}-}^{\lambda}\left(i_{1}\right)=1, \eta_{a_{\lambda} T_{q+1}-}^{\lambda}\left(i_{2}\right)=0$. Recall that $x$ is at the boundary of two cells $c_{-}, c_{+}$.

We have either $H_{T_{q+1}-}(x)>0$ or $Z_{T_{q+1}-}\left(c_{-}\right)<1$ (because $Z_{T_{q+1}-}\left(c_{+}\right)=1$ by assumption). Clearly, $x=X_{k}$ for some $k \leq q$, with $Z_{T_{k}-}\left(X_{k}\right)<1$ (else, we would have $H_{t}(x)=0$ and $Z_{t}\left(c_{-}\right)=Z_{t}\left(c_{+}\right)$for all $\left.t \in\left[0, T_{q+1}\right)\right)$. Thus, recalling (3.10.4),

$$
T_{k}-Z_{T_{k}-}\left(X_{k}\right)=\tau_{T_{k}-}\left(X_{k}\right)=\tau_{T_{k}-}^{\lambda}\left(X_{k}\right)
$$

so that $\left(X_{k}\right)_{\lambda}$ is completely empty at time $\boldsymbol{a}_{\lambda}\left(T_{k}-Z_{T_{k}-}\left(X_{k}\right)\right)$.

Case 1. - Assume first that $H_{T_{q+1}-}(x)>0$. Then by construction, see Algorithm 3.9.3 (with $\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}$ replaced by $Z_{T_{k}-}\left(X_{k}\right)$ ), there holds

$$
T_{k}+Z_{T_{k}-}\left(X_{k}\right)>T_{q+1}>T_{k}
$$

whence by $\Omega_{M}(\alpha), T_{k}+Z_{T_{k}-}\left(X_{k}\right)>T_{q+1}+\alpha>T_{k}+2 \alpha$.
Consider $C=C\left(\eta_{a_{\lambda} T_{k}-}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} X_{k}\right\rfloor\right)$. By $\Omega_{2}^{S}(\lambda)$, we have

$$
C \subset\left[\left[\left\lfloor\boldsymbol{n}_{\lambda} X_{k}-\frac{1}{2} \boldsymbol{m}_{\lambda}\right\rfloor,\left\lfloor\boldsymbol{n}_{\lambda} X_{k}+\frac{1}{2} \boldsymbol{m}_{\lambda}\right\rfloor\right]\right]
$$

(because $\left(X_{k}\right)_{\lambda}$ is completely empty at time $\boldsymbol{a}_{\lambda}\left(T_{k}-Z_{T_{k}-}\left(X_{k}\right)\right)$, because $T_{k}-$ $Z_{T_{k}-}\left(X_{k}\right)$ and $T_{k}$ belong to $\mathcal{T}_{M}$ and because $\left.0<Z_{T_{k}-}\left(X_{k}\right)<1\right)$.

The component $C$ is destroyed at time $T_{S} T_{k}$. By Definition of $\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}^{k, \lambda}$, see Lemma 3.10.2, we deduce that $C$ is not completely occupied at time

$$
\boldsymbol{a}_{\lambda}\left(T_{k}+\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}^{k, \lambda}\right)
$$

But by $\Omega_{4}^{S}(\gamma, \lambda)$ we see that $\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}^{k, \lambda} \geq Z_{T_{k}-}\left(X_{k}\right)-\gamma$, whence

$$
T_{k}+\Theta_{T_{k}-Z_{T_{k}-}\left(X_{k}\right), T_{k}}^{k, \lambda} \geq T_{k}+Z_{T_{k}-}\left(X_{k}\right)-\gamma>T_{q+1}
$$

since $\gamma<\alpha$. All this implies that $C$ is not completely occupied at time $\boldsymbol{a}_{\lambda} T_{q+1}-$.
Finally, using again $\Omega_{2}^{S}(\lambda)$ there is necessarily (at least) one seed falling on a site in $\llbracket\left\lfloor\boldsymbol{n}_{\lambda} X_{k}-\boldsymbol{m}_{\lambda}+1\right\rfloor,\left\lfloor\boldsymbol{n}_{\lambda} X_{k}-\frac{1}{2} \boldsymbol{m}_{\lambda}-1\right\rfloor \rrbracket \subset\left(X_{k}\right)_{\lambda}$ during $\left(\boldsymbol{a}_{\lambda} T_{q}, \boldsymbol{a}_{\lambda} T_{q+1}\right)$. This shows the result.

Case 2. - Assume next that $H_{T_{q+1}-}(x)=0$ and $T_{q+1}-\left[T_{k}-Z_{T_{k}-}\left(X_{k}\right)\right]<1$. Recall that $\left(X_{k}\right)_{\lambda}$ is completely empty at time $\boldsymbol{a}_{\lambda}\left(T_{k}-Z_{T_{k}-}\left(X_{k}\right)\right)$. Since $T_{k}-$ $Z_{T_{k}-}\left(X_{k}\right)$ and $T_{q+1}$ belong to $\mathcal{T}_{M}$ and since their difference is smaller than 1 by assumption, $\Omega_{2}^{S}(\lambda)$ guarantees us the existence of $i_{1}<i_{2}<i_{3}$, all in $\left(X_{k}\right)_{\lambda}$, such that (at least) one seed falls on $i_{2}$ and no seed fall on $i_{1}$ nor on $i_{3}$ during $\left(\boldsymbol{a}_{\lambda}\left(T_{k}-Z_{T_{k}-}\left(X_{k}\right)\right), \boldsymbol{a}_{\lambda} T_{q+1}\right)$. One easily concludes that $i_{2}$ is occupied and $i_{3}$ is vacant at time $\boldsymbol{a}_{\lambda} T_{q+1}-$, as desired.
Case 3. - Assume finally that $H_{T_{q+1}-}(x)=0$ and $T_{q+1}-\left[T_{k}-Z_{T_{k}-}\left(X_{k}\right)\right] \geq 1$, whence $T_{q+1}-\left[T_{k}-Z_{T_{k}-}\left(X_{k}\right)\right] \geq 1+\alpha$ by $\Omega_{M}(\alpha)$. Since $H_{T_{q+1}-}(x)=0$, there holds $Z_{T_{q+1}-}\left(c_{-}\right)<1=Z_{T_{q+1}-}\left(c_{+}\right)$and $T_{k}+Z_{T_{k}-}\left(X_{k}\right) \leq T_{q+1}$, so that $T_{k}+Z_{T_{k}-}\left(X_{k}\right) \leq$ $T_{q+1}-\alpha$.
We aim to use the event $\Omega_{1}^{S}(\lambda)$. We introduce

$$
t_{0}=T_{k}-Z_{T_{k}-}\left(X_{k}\right)=\tau_{T_{k}-}\left(X_{k}\right)=\tau_{T_{k}-}^{\lambda}\left(X_{k}\right) .
$$

Observe that $\tau_{T_{k}-}\left(c_{-}\right)=\tau_{T_{k}-}\left(c_{+}\right)=\tau_{T_{k}-}(x)$ because there has been no fire (exactly) at $x$ during $\left[0, T_{k}\right)$. Thus

$$
Z_{t_{0}-}(x)=Z_{t_{0}-}\left(x_{-}\right)=Z_{t_{0}-}\left(x_{+}\right)=1 \quad \text { and } \quad Z_{t_{0}}(x)=Z_{t_{0}}\left(c_{-}\right)=Z_{t_{0}}\left(c_{+}\right)=0
$$

Set now $t_{1}=T_{k}$ and $s=T_{q+1}$. Observe that $0<t_{1}-t_{0}<1$. Necessarily, $Z_{t}\left(c_{-}\right)$has jumped to 0 at least one time between $t_{0}$ and $T_{q+1}-$ (else, one would
have $Z_{T_{q+1}-}\left(c_{-}\right)=1$, since $T_{q+1}-t_{0} \geq 1$ by assumption) and this jump occurs after $t_{0}+1>t_{1}$ (since a jump of $Z_{t}\left(c_{-}\right)$requires that $Z_{t}\left(c_{-}\right)=1$, and since for all $\left.t \in\left[t_{0}, t_{0}+1\right), Z_{t}\left(c_{-}\right)=t-t_{0}<1\right)$.

We thus may denote by $t_{2}<t_{3}<\cdots<t_{K}$, for some $K \geq 2$, the successive times of jumps of the process $\left(Z_{t}\left(c_{-}\right), Z_{t}\left(c_{+}\right)\right)$during $\left(t_{0}+1, s\right)$. We also put $\varepsilon=1$ if $t_{2}$ is a jump of $Z_{t}\left(c_{+}\right)$and $\varepsilon=-1$ else. Then we prove exactly as in Lemma 3.9.5, step 6 , case 3 that $\mathcal{R}=\left\{\varepsilon, t_{0}, \ldots, t_{K} ; s\right\}$ necessarily satisfies the condition (PP).

Next, $t_{2}-t_{1}<Z_{T_{k}-}\left(X_{k}\right)=t_{1}-t_{0}$, because else, we would have $H_{t_{2}-}\left(X_{k}\right)=0$ and thus the fire destroying $c_{+}$(or $c_{-}$) at time $t_{2}$ would also destroy $c_{-}$(or $c_{+}$), we thus would have $Z_{t_{2}}\left(c_{+}\right)=Z_{t_{2}}\left(c_{-}\right)=0$, so that $Z_{t}\left(c_{+}\right)$and $Z_{t}\left(c_{-}\right)$would remain equal forever.

Finally, we check as in Lemma 3.9.5, step 6, case 3 that

$$
\left(\eta_{a_{\lambda} t}^{\lambda}(i)\right)_{t \geq t_{0}, i \in x_{\lambda}}=\left(\zeta_{t}^{\lambda, \mathcal{R}, k}\left(i+\left\lfloor\boldsymbol{n}_{\lambda} x\right\rfloor\right)\right)_{t \geq t_{0}, i \in x_{\lambda}},
$$

this last process being built upon the family $\left(N_{t}^{S, k}(i)\right)_{t \geq t_{0}, i \in x_{\lambda}}$ as in subsection 3.10.3.
We thus can use $\Omega_{1}^{S}(\lambda)$ and conclude that there are some sites $i_{1}<i_{2}$ in $x_{\lambda}$ with $\eta_{T_{S} T_{q+1-}}^{\lambda}\left(i_{1}\right)=1$ and $\eta_{T_{S} T_{q+1-}}^{\lambda}\left(i_{2}\right)=0$ as desired.

Step 7. - The conclusion follows from the previous steps exactly as in the proof of Lemma 3.9.5, step 7: it suffices to replace everywhere $T_{S}$ by $\boldsymbol{a}_{\lambda}$.
3.10.7. Conclusion. - To achieve the proof, we will need the following result.

Lemma 3.10.5. - Let $\left(N_{t}^{S}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$ be a family of i.i.d. $\operatorname{SR}\left(\mu_{S}\right)$-processes, and define

$$
\zeta_{t}^{\lambda}(i)=\min \left(N_{\boldsymbol{a}_{\lambda} t}^{S}(i), 1\right)
$$

(i) Put $K_{t}^{\lambda}=\left(2 \boldsymbol{m}_{\lambda}+1\right)^{-1}\left|\left\{i \in \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket: \zeta_{t}^{\lambda}(i)>0\right\}\right|$ and

$$
U_{t}^{\lambda}=\left(\frac{\psi_{S}\left(K_{t}^{\lambda}\right)}{a_{\lambda}}\right) \wedge 1
$$

recall notation 2.1.5. Then for any $\varepsilon>0$, any $T>0$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\sup _{[0, T]}\left|U_{t}^{\lambda}-t \wedge 1\right|>\varepsilon\right]=0
$$

(ii) Put also $C_{t}^{\lambda}=C\left(\zeta_{t}^{\lambda}, 0\right)$ and define

$$
V_{t}^{\lambda}=\left(\boldsymbol{a}_{\lambda}^{-1} \psi_{S}\left(1-1 /\left|C_{t}^{\lambda}\right|\right) \mathbb{1}_{\left\{\left|C_{t}^{\lambda}\right|>0\right\}}\right) \wedge 1 .
$$

Then for any $\varepsilon>0$, for all $t \in[0,1)$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[C_{t}^{\lambda} \subset \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket,\left|V_{t}^{\lambda}-t\right|<\varepsilon\right]=1 .
$$

Proof. - We split the proof into three steps.
Step 1. - Here we show that for $t \geq 0$ fixed,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|U_{t}^{\lambda}-t \wedge 1\right|>\varepsilon\right]=0
$$

Case 1. - Assume first that $t \geq 1$. Then Lemma 3.10.1(ii) implies that $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[K_{t}^{\lambda}=1\right]=1$. But $K_{t}^{\lambda}=1$ implies that $U_{t}^{\lambda}=\left[\psi_{S}(1) / \boldsymbol{a}_{\lambda}\right] \wedge 1=1$ (because $\psi_{S}(1)=\infty$ ).
Case 2. - Assume next that $t<1$. Then the random variable $X_{t}^{\lambda}=\left(2 m_{\lambda}+1\right) K_{t}^{\lambda}$ has a binomial distribution with parameters $2 \boldsymbol{m}_{\lambda}+1$ and $\nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda} t\right)\right)$. Let $\varepsilon \in(0, t)$ be fixed. Then, using Bienaymé-Chebyshev's inequality,

$$
\begin{aligned}
\operatorname{Pr} & {\left[K_{t}^{\lambda} \leq \nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda}(t-\varepsilon)\right)\right)\right] } \\
& =\operatorname{Pr}\left[X_{t}^{\lambda} \leq\left(2 \boldsymbol{m}_{\lambda}+1\right) \nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda}(t-\varepsilon)\right)\right)\right] \\
& \leq \operatorname{Pr}\left[\left|X_{t}^{\lambda}-\left(2 \boldsymbol{m}_{\lambda}+1\right) \nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda} t\right)\right)\right| \geq\left(2 \boldsymbol{m}_{\lambda}+1\right) \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}(t-\varepsilon), \boldsymbol{a}_{\lambda} t\right)\right)\right] \\
& \leq \frac{\left(2 \boldsymbol{m}_{\lambda}+1\right) \nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda} t\right)\right) \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)}{\left(2 \boldsymbol{m}_{\lambda}+1\right)^{2} \nu_{S}^{2}\left(\left(\boldsymbol{a}_{\lambda}(t-\varepsilon), \boldsymbol{a}_{\lambda} t\right)\right)} \leq \frac{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)}{\left(2 \boldsymbol{m}_{\lambda}+1\right) \nu_{S}^{2}\left(\left(\boldsymbol{a}_{\lambda}(t-\varepsilon), \boldsymbol{a}_{\lambda} t\right)\right)} .
\end{aligned}
$$

This last quantity tends to 0 . Indeed, $\left(H_{S}(\infty)\right)$ implies that

$$
\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}(t-\varepsilon), \boldsymbol{a}_{\lambda} t\right)\right) \sim \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}(t-\varepsilon), \infty\right)\right) \geq \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)
$$

and it suffices to use that $\boldsymbol{m}_{\lambda} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right) \rightarrow \infty$ by (2.2.4), since $t<1$.
By the same way, for $\varepsilon>0$,

$$
\begin{aligned}
\operatorname{Pr} & {\left[K_{t}^{\lambda} \geq \nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda}(t+\varepsilon)\right)\right)\right] } \\
& =\operatorname{Pr}\left[X_{t}^{\lambda} \geq\left(2 \boldsymbol{m}_{\lambda}+1\right) \nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda}(t+\varepsilon)\right)\right)\right] \\
& \leq \operatorname{Pr}\left[\left|X_{t}^{\lambda}-\left(2 \boldsymbol{m}_{\lambda}+1\right) \nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda} t\right)\right)\right| \geq\left(2 \boldsymbol{m}_{\lambda}+1\right) \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \boldsymbol{a}_{\lambda}(t+\varepsilon)\right)\right)\right] \\
& \leq \frac{\left(2 \boldsymbol{m}_{\lambda}+1\right) \nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda} t\right)\right) \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)}{\left(2 \boldsymbol{m}_{\lambda}+1\right)^{2} \nu_{S}^{2}\left(\left(\boldsymbol{a}_{\lambda} t, \boldsymbol{a}_{\lambda}(t+\varepsilon)\right)\right)} \leq \frac{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)}{\left(2 \boldsymbol{m}_{\lambda}+1\right) \nu_{S}^{2}\left(\left(\boldsymbol{a}_{\lambda} t, \boldsymbol{a}_{\lambda}(t+\varepsilon)\right)\right)},
\end{aligned}
$$

which also tends to 0 , because $\left(H_{S}(\infty)\right)$ implies that

$$
\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \boldsymbol{a}_{\lambda}(t+\varepsilon)\right)\right) \sim \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)
$$

and because $\boldsymbol{m}_{\lambda} \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right) \rightarrow \infty$, since $t<1$.
To conclude the step it suffices to note that for $0<t-\varepsilon<t<t+\varepsilon<1$, $K_{t}^{\lambda} \in\left(\nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda}(t-\varepsilon)\right)\right), \nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda}(t+\varepsilon)\right)\right)\right)$ implies that $U_{t}^{\lambda} \in(t-\varepsilon, t+\varepsilon)$ by definition of $\psi_{S}$.

Step 2. - Using a well suited version of the Dini theorem, we conclude the proof of (i). Indeed, let $\varepsilon>0$ and consider a subdivision $0=t_{0}<t_{1}<\cdots<t_{\ell}=T$, with $t_{i+1}-t_{i}<\frac{1}{2} \varepsilon$. Using step 1 , we see that

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\max _{i=0, \ldots, \ell}\left|U_{t_{i}}^{\lambda}-t_{i} \wedge 1\right|>\frac{1}{2} \varepsilon\right]=0
$$

Observe that $t \mapsto U_{t}^{\lambda}$ is a.s. nondecreasing and that $t \mapsto t \wedge 1$ is nondecreasing and Lipschitz continuous. We deduce that

$$
\sup _{[0, T]}\left|U_{t}^{\lambda}-t \wedge 1\right| \leq \frac{1}{2} \varepsilon+\max _{i=0, \ldots, \ell}\left|U_{t_{i}}^{\lambda}-t_{i} \wedge 1\right| .
$$

One immediately concludes.

Step 3. - It remains to prove (ii). Let thus $t<1$ and $\varepsilon>0$ be fixed. We can of course assume that $0<t-\varepsilon<t<t+\varepsilon<1$.

First, $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[C_{t}^{\lambda} \subset \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket\right]=1$ due to Lemma 3.10.1 (i).
Next, each site is vacant with probability $\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)$. It is thus classical that as $\lambda \rightarrow 0, \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)\left|C_{t}^{\lambda}\right|$ goes in law to a random variable $X$ with density $x \mathrm{e}^{-x} \mathbb{1}_{x>0}$. Indeed,
$\triangleright$ for $Y_{\delta}$ a geometric random variable with parameter $\delta$, the random variable $\delta Y_{\delta}$ goes in law, as $\delta \rightarrow 0$, to an exponentially distributed random variable with parameter 1 ;
$\triangleright\left|C_{t}^{\lambda}\right|$ is the sum of two independent geometric random variables, both with parameter $\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)$;
$\triangleright x \mathrm{e}^{-x} \mathbb{1}_{x>0}$ is the density of the sum of two independent exponentially distributed random variables with parameter 1.
For $\delta>0$, consider $0<a<1<b$ such that $\operatorname{Pr}[X \in(a, b))] \geq 1-\delta$. Then

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|C_{t}^{\lambda}\right| \in\left(a / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right), b / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)\right] \geq 1-\delta\right.
$$

But due to $\left(H_{S}(\infty)\right),\left|C_{t}^{\lambda}\right| \in\left(a / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right), b / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} t, \infty\right)\right)\right.$ implies, if $\lambda$ is small enough, that $\left|C_{t}^{\lambda}\right| \in\left(1 / \nu_{S}\left(\left(a_{\lambda}(t-\varepsilon), \infty\right)\right), 1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}(t+\varepsilon), \infty\right)\right)\right.$, whence finally

$$
V_{t}^{\lambda} \in\left(\boldsymbol{a}_{\lambda}^{-1} \psi_{S}\left(\nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda}(t-\varepsilon)\right)\right)\right), \boldsymbol{a}_{\lambda}^{-1} \psi_{S}\left(\nu_{S}\left(\left(0, \boldsymbol{a}_{\lambda}(t+\varepsilon)\right)\right)\right)\right)=(t-\varepsilon, t+\varepsilon) .
$$

We have proved that for all $\delta>0, \liminf _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|V_{t}^{\lambda}-t\right|<\varepsilon\right] \geq 1-\delta$, which concludes the proof.

We finally give the
Proof of Proposition 3.8.1 when $\beta=\infty$. - Let us fix $x_{0} \in(-A, A), t_{0} \in(0, T] \backslash\{1\}$ and $\varepsilon>0$. We will prove that with our coupling (see subsection 3.9.3), there holds
(a) $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\boldsymbol{\delta}\left(D_{t_{0}}^{\lambda}\left(x_{0}\right), D_{t_{0}}\left(x_{0}\right)\right)>\varepsilon\right]=0$;
(b) $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\boldsymbol{\delta}_{T}\left(D^{\lambda}\left(x_{0}\right), D\left(x_{0}\right)\right)>\varepsilon\right]=0$;
(c) $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\sup _{[0, T]}\left|Z_{t}^{\lambda}\left(x_{0}\right)-Z_{t}\left(x_{0}\right)\right| \geq \varepsilon\right]=0$;
(d) $\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|W_{t_{0}}^{\lambda}\left(x_{0}\right)-Z_{t_{0}}\left(x_{0}\right)\right|>\varepsilon\right]=0$, where

$$
W_{t_{0}}^{\lambda}\left(x_{0}\right)=\left(\frac{\psi_{S}\left(1-1 /\left|C_{A}\left(\eta_{a_{\lambda} t_{0}}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor\right)\right|\right) \mathbb{1}_{\left\{\left|C_{A}\left(\eta_{\boldsymbol{a}_{\lambda} t_{0}},\left\lfloor n_{\lambda} x_{0}\right\rfloor\right)\right|>0\right\}}}{\boldsymbol{a}_{\lambda}}\right) \wedge 1 .
$$

These points will clearly imply the result.
First, we introduce, for $\zeta>0$, the event $\Omega_{A, T}^{x_{0}}(\zeta)$ on which $x_{0} \notin \bigcup_{q=1}^{n}\left[X_{q}-\zeta, X_{q}+\zeta\right]$. The probability of this event obviously tends to 1 as $\zeta \rightarrow 0$.

On $\Omega_{A, T}^{x_{0}}(\zeta)$, we have, for $\lambda>0$ small enough (say, such that $4 \boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}<\zeta$ ), $\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor \notin \bigcup_{q=1}^{n}\left(X_{q}\right)_{\lambda}$. We then call $c_{0} \in \mathcal{C}_{M}$ the cell containing $x_{0}$.

Step 1. - As in the case where $\beta=B S$, (a) implies (b) (the fact that $t_{0}=1$ is excluded in (a) is of course not a problem, because $\{1\}$ is Lebesgue-negligible).

Step 2. - Due to Lemma 3.10.4, we know that if $0<\gamma<\alpha$, on $\Omega(\alpha, \gamma, \lambda) \cap \Omega_{A, T}^{x_{0}}(\zeta)$, $\tau_{t}^{\lambda}\left(c_{0}\right)=\rho_{t}^{\lambda}\left(c_{0}\right)=\tau_{t}\left(x_{0}\right)$ for all $t \in[0, T]$. This implies that for all $i \in\left(c_{0}\right)_{\lambda}$, for all $t \in[0, T]$,

$$
\eta_{T_{S} t}^{\lambda}(i)=\min \left(N_{\boldsymbol{a}_{\lambda} t}^{S, 0}(i)-N_{\boldsymbol{a}_{\lambda} \tau_{t}\left(x_{0}\right)}^{S, 0}(i), 1\right) .
$$

We also recall that by construction, $\left(\tau_{t}\left(x_{0}\right)\right)_{t \geq 0}$ is independent of $\left(N_{t}^{S, 0}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$.
Step 3. - Here we prove (d). Let $\delta>0$ be fixed. We first consider $\alpha_{0}>0$, $\gamma_{0} \in\left(0, \alpha_{0}\right), \zeta_{0}>0$ and $\lambda_{0}>0$ such that for all $\lambda \in\left(0, \lambda_{0}\right)$,

$$
\operatorname{Pr}\left[\Omega\left(\alpha_{0}, \gamma_{0}, \lambda\right) \cap \Omega_{A, T}^{x_{0}}\left(\zeta_{0}\right)\right]>1-\delta
$$

Then we consider $\lambda_{1} \leq \lambda_{0}$ in such a way that for $\lambda \in\left(0, \lambda_{1}\right)$,

$$
\left[\left[\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor-\boldsymbol{m}_{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor+\boldsymbol{m}_{\lambda}\right]\right] \subset\left(c_{0}\right)_{\lambda}
$$

(this can be done properly by using $\Omega_{A, T}^{x_{0}}(\zeta)$ and the fact that $\boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda} \rightarrow 0$ ).
Introduce $C_{t}^{\lambda}$ and $V_{t}^{\lambda}$ as in Lemma 3.10.5 (ii), using the seed processes

$$
\left(N_{t+\tau_{t}\left(x_{0}\right) / \boldsymbol{a}_{\lambda}}^{S, \lambda}\left(i+\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor\right)-N_{\tau_{t}\left(x_{0}\right) / a_{\lambda}}^{S}\left(i+\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor\right)\right)_{t \geq 0, i \in \mathbb{Z}}
$$

Then by step 2 , we observe that $C_{t_{0}-\tau_{t}\left(x_{0}\right)}^{\lambda} \subset \llbracket-\boldsymbol{m}_{\lambda}, \boldsymbol{m}_{\lambda} \rrbracket$ implies that, on $\Omega(\alpha, \gamma, \lambda) \cap \Omega_{A, T}^{x_{0}}(\zeta)$ and for $\lambda<\lambda_{1}$,

$$
C_{A}\left(\eta_{\boldsymbol{a}_{\lambda} t_{0}}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor\right)=\left\{i+\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor: i \in C_{t_{0}-\tau_{t}\left(x_{0}\right)}^{\lambda}\right\}
$$

whence $W_{t_{0}}^{\lambda}\left(x_{0}\right)=V_{t_{0}-\tau_{t_{0}}\left(x_{0}\right)}^{\lambda}$. All this implies, using Lemma 3.10 .5 (ii), that

$$
\liminf _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|W_{t_{0}}^{\lambda}\left(x_{0}\right)-\left(t_{0}-\tau_{t_{0}}\left(x_{0}\right)\right)\right|<\varepsilon \mid t_{0}-\tau_{t_{0}}\left(x_{0}\right)<1\right] \geq 1-\delta
$$

Recalling finally (3.10.3), we deduce that

$$
\liminf _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|W_{t_{0}}^{\lambda}\left(x_{0}\right)-Z_{t_{0}}\left(x_{0}\right)\right|<\varepsilon \mid t_{0}-\tau_{t_{0}}\left(x_{0}\right)<1\right] \geq 1-\delta
$$

If now $t_{0}-\tau_{t_{0}}\left(x_{0}\right)>1$, then step 2 and $\Omega_{3}^{S}(\lambda)$ imply that $\left(c_{0}\right)_{\lambda}$ is completely occupied at time $\boldsymbol{a}_{\lambda} t_{0}$. Hence

$$
\left|C\left(\eta_{\boldsymbol{a}_{\lambda} t_{0}}^{\lambda},\left\lfloor\boldsymbol{n}_{\lambda} x_{0}\right\rfloor\right)\right| \geq\left|\left(c_{0}\right)_{\lambda}\right| \simeq|c| \boldsymbol{n}_{\lambda} \geq \alpha \boldsymbol{n}_{\lambda}
$$

by $\Omega_{M}(\alpha)$. Consequently,

$$
W_{t_{0}}^{\lambda}\left(x_{0}\right) \geq\left[\boldsymbol{a}_{\lambda}^{-1} \psi_{S}\left(1-1 /\left(\alpha \boldsymbol{n}_{\lambda}\right)\right)\right] \wedge 1 \simeq\left[\boldsymbol{a}_{\lambda}^{-1} \psi_{S}\left(1-\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right) / \alpha\right)\right] \wedge 1
$$

For $\varepsilon>0, \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right) / \alpha \leq \nu_{S}\left(\left((1-\varepsilon) \boldsymbol{a}_{\lambda}, \infty\right)\right)$ for all $\lambda$ small enough: use $\left(H_{S}(\infty)\right)$.
Thus for all $\lambda$ small enough, on $\Omega(\alpha, \gamma, \lambda) \cap \Omega_{A, T}^{x_{0}}(\zeta)$, we have

$$
W_{t_{0}}^{\lambda}\left(x_{0}\right) \geq\left[\boldsymbol{a}_{\lambda}^{-1} \psi_{S}\left(1-\nu_{S}\left(\left((1-\varepsilon) \boldsymbol{a}_{\lambda}, \infty\right)\right)\right)\right] \wedge 1=1-\varepsilon
$$

by definition of $\psi_{S}$. Thus

$$
\liminf _{\lambda \rightarrow 0} \operatorname{Pr}\left[W_{t_{0}}^{\lambda}\left(x_{0}\right) \in(1-\varepsilon, 1] \mid t_{0}-\tau_{t_{0}}\left(x_{0}\right)>1\right] \geq 1-\delta .
$$

Recalling (3.10.3), we deduce that

$$
\liminf _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|W_{t_{0}}^{\lambda}\left(x_{0}\right)-Z_{t_{0}}\left(x_{0}\right)\right|<\varepsilon \mid t_{0}-\tau_{t_{0}}\left(x_{0}\right)>1\right] \geq 1-\delta
$$

Finally, we observe that a.s., $t_{0}-\tau_{t_{0}}\left(x_{0}\right) \neq 1$. Indeed, we have excluded $t_{0}=1$ and the only value charged with positive probability by $\tau_{t_{0}}\left(x_{0}\right)$ is 0 . Thus

$$
\liminf _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|W_{t_{0}}^{\lambda}\left(x_{0}\right)-Z_{t_{0}}\left(x_{0}\right)\right|<\varepsilon\right] \geq 1-\delta
$$

Since this holds for any $\delta>0$, this concludes the proof of (d).
Step 4. - Next, (c) is proved exactly as when $\beta=B S$ (change the beginning: let first $\delta>0, \alpha_{0}>0, \zeta_{0} \in\left(0, \alpha_{0}\right)$ and $\lambda_{0}>0$ be as in step 3 ; replace everywhere $T_{S}$ by $\boldsymbol{a}_{\lambda}$; and make use of Lemma 3.10.5 instead of Lemma 3.9.6).

Step 5. - Finally, (a) is also proved as when $\beta=B S$. The only difference is that when put $\mathcal{T}_{M}^{*}=\mathcal{T}_{M} \cup\left\{t_{0}\right\}$, we need that $t_{0} \neq 1$ (because $0 \in \mathcal{T}_{M}$ and $\Omega_{M}^{*}(\alpha)$ will thus require that for $\left.\left|t_{0}-1\right|>\alpha\right)$.

### 3.11. Cluster-size distribution when $\beta \in\{\infty, B S\}$

The aim of this section is to prove Corollaries 2.3.4 and 2.4.5.
3.11.1. Study of the $\operatorname{LFF}(\infty)$ and $\operatorname{LFF}(B S)$-processes. - We first extend $[\mathbf{1 5}$, Lemma 17].

Lemma 3.11.1. - Let $\beta \in\{\infty, B S\}$. Let $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ be a $\operatorname{LFF}(\beta)$-process. There are some constants $0<c_{1}<c_{2}$ and $0<\kappa_{1}<\kappa_{2}$ such that the following estimates hold.
(i) For any $t \in(1, \infty)$, any $x \in \mathbb{R}$, any $z \in[0,1), \operatorname{Pr}\left[Z_{t}(x)=z\right]=0$.
(ii) For any $t \in[0, \infty)$, any $B>0$, any $x \in \mathbb{R}, P\left[\left|D_{t}(x)\right|=B\right]=0$.
(iii) For all $t \in[0, \infty)$, all $x \in \mathbb{R}$, all $B>0, \operatorname{Pr}\left[\left|D_{t}(x)\right| \geq B\right] \leq c_{2} \mathrm{e}^{-\kappa_{1} B}$.
(iv) For all $t \in\left[\frac{3}{2}, \infty\right)$, all $x \in \mathbb{R}$, all $B>0, \operatorname{Pr}\left[\left|D_{t}(x)\right| \geq B\right] \geq c_{1} \mathrm{e}^{-\kappa_{2} B}$.
(v) For all $t \in\left[\frac{5}{2}, \infty\right)$, all $0 \leq a<b<1$, all $x \in \mathbb{R}$,

$$
c_{1}(b-a) \leq \operatorname{Pr}\left(Z_{t}(x) \in[a, b]\right) \leq c_{2}(b-a)
$$

Proof. - By invariance by translation, it suffices to treat the case $x=0$. When $\beta=B S$, the function $F_{S}$ was defined in Definition 2.4.1. Recall that the $\operatorname{LFF}(\infty)-$ process can be viewed as a $\operatorname{LFF}(B S)$-process with the function $F_{S}(z, v)=z$, see Remark 3.6.1.

We consider a Poisson measure $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x, \mathrm{~d} v)$ on $[0, \infty) \times \mathbb{R} \times[0,1]$ with intensity measure $\mathrm{d} t \mathrm{~d} x \mathrm{~d} v$. We also denote by $\pi_{M}(\mathrm{~d} t, \mathrm{~d} x)=\int_{v \in[0,1]} \pi_{M}(\mathrm{~d} t, \mathrm{~d} x, \mathrm{~d} v)$.

Point (i). - For $t \in[0,1]$, we have a.s. $Z_{t}(0)=t$. But for $t>1$ and $z \in[0,1)$, $Z_{t}(0)=z$ implies that the cluster containing 0 has been killed at time $t-z$, so that necessarily $\pi_{M}(\{t-z\} \times \mathbb{R})>0$. This happens with probability 0 .

Point (ii). - For any $t>0,\left|D_{t}(0)\right|$ is either 0 or of the form $\left|X_{i}-X_{j}\right|$ (with $i \neq j)$, where $\left(T_{i}, X_{i}\right)_{i \geq 1}$ are the marks of the Poisson measure $\pi_{M}(\mathrm{~d} s, \mathrm{~d} x)$ restricted to $[0, t] \times \mathbb{R}$. We easily conclude as previously that for $B>0, \operatorname{Pr}\left(\left|D_{t}(0)\right|=B\right)=0$.

Figure 9. The event $\Omega_{t, B}$.

Point (iii). - First if $t \in[0,1)$, we have a.s. $\left|D_{t}(0)\right|=0$ and the result is obvious. Recall now that $v_{0} \in[0,1)$ was defined in Lemma 3.6.5 and that for $(\tau, X, V)$ a mark of $\pi_{M}$ such that $V \geq v_{0}$, we have $H_{t}(X)>0$ or $Z_{t}(X)<1$ for all $t \in\left[\tau, \tau+\frac{1}{4}\right]$ (see the proof of Proposition 3.6.4, step 1). This implies that for $t \geq 1$,
$\left\{D_{t}(0) \geq B\right\} \subset\left\{\left[0, \frac{1}{2} B\right]\right.$ is connected at time $t$ or

$$
\left.\left[-\frac{1}{2} B, 0\right] \text { is connected at time } t\right\}
$$

$\subset\left\{\pi_{M}\left(\left[t-\frac{1}{4}, t\right] \times\left[0, \frac{1}{2} B\right] \times\left[v_{0}, 1\right]\right)=0\right\}$

$$
\cup\left\{\pi_{M}\left(\left[t-\frac{1}{4}, t\right] \times\left[-\frac{1}{2} B, 0\right] \times\left[v_{0}, 1\right]\right)=0\right\} .
$$

Consequently, $\operatorname{Pr}\left[\left|D_{t}(0)\right| \geq B\right] \leq 2 \mathrm{e}^{-\frac{1}{8}\left(1-v_{0}\right) B}$ as desired.
Point (iv). - Fix $t \geq \frac{3}{2}$ and $B>0$. Consider the event $\Omega_{t, B}=\Omega_{t, B}^{1} \cap \Omega_{t}^{2} \cap \Omega_{t, B}^{3}$, illustrated by Figure 9, where
$\triangleright \Omega_{t, B}^{1}=\left\{\pi_{M}\left(\left[t-\frac{3}{2}, t\right] \times[0, B] \times[0,1]\right)=0\right\} ;$
$\triangleright \Omega_{t}^{2}$ is the event that in the box $\left[t-\frac{3}{2}, t\right] \times[-1,0] \times[0,1], \pi_{M}$ has exactly five marks $\left(S_{i}, Y_{i}, V_{i}\right)_{i=1, \ldots, 5}$ with $Y_{5}<Y_{4}<Y_{3}<Y_{2}<Y_{1}, \min _{i=1, \ldots, 5} V_{i}>v_{0}$ and $t-\frac{3}{2}<S_{1}<t-1, S_{1}<S_{2}<S_{1}+\frac{1}{4}, S_{2}<S_{3}<S_{2}+\frac{1}{4}, S_{3}<S_{4}<S_{3}+\frac{1}{4}$, $S_{4}<S_{5}<S_{4}+\frac{1}{4}$ and $S_{5}+\frac{1}{4}>t$.
$\triangleright \Omega_{t, B}^{3}$ is the event that in the box $\left[t-\frac{3}{2}, t\right] \times[B, B+1] \times[0,1], \pi_{M}$ has exactly five marks $\left(\widetilde{S}_{i}, \widetilde{Y}_{i}, \widetilde{V}_{i}\right)_{i=1, \ldots, 5}$ with $\widetilde{Y}_{1}<\widetilde{Y}_{2}<\widetilde{Y}_{3}<\widetilde{Y}_{4}<\widetilde{Y}_{5}$, $\min _{i=1, \ldots, 5} \widetilde{V}_{i}>v_{0}$ and $t-\frac{3}{2}<\widetilde{S}_{1}<t-1, \widetilde{S}_{1}<\widetilde{S}_{2}<\widetilde{S}_{1}+\frac{1}{4}$, $\widetilde{S}_{2}<\widetilde{S}_{3}<\widetilde{S}_{2}+\frac{1}{4}, \widetilde{S}_{3}<\widetilde{S}_{4}<\widetilde{S}_{3}+\frac{1}{4}, \widetilde{S}_{4}<\widetilde{S}_{5}<\widetilde{S}_{4}+\frac{1}{4}$ and $\widetilde{S}_{5}+\frac{1}{4}>t$.
We of course have $p:=\operatorname{Pr}\left(\Omega_{t}^{2}\right)=\operatorname{Pr}\left(\Omega_{t, B}^{3}\right)>0$, and this probability does not depend on $t \geq \frac{3}{2}$ nor on $B>0$. Furthermore, $\operatorname{Pr}\left(\Omega_{t, B}^{1}\right)=\mathrm{e}^{-\frac{3}{2} B}$. These three events being independent, we conclude that $\operatorname{Pr}\left(\Omega_{t, B}\right) \geq p^{2} \mathrm{e}^{-3 B / 2}$. To conclude the proof of (iv), it thus suffices to check that $\Omega_{t, B} \subset\left\{[0, B] \subset D_{t}(0)\right\}$. But on $\Omega_{t, B}$, using the same arguments as in Point (iii), we observe that:
$\triangleright$ the fire starting at $\left(S_{2}, Y_{2}\right)$ can not affect $[0, B]$, because since $S_{2} \in\left[S_{1}, S_{1}+\frac{1}{4}\right)$, $H_{S_{2}-}\left(Y_{1}\right)>0$ or $Z_{S_{2}-}\left(Y_{1}\right)>0$, with $Y_{2}<Y_{1}<0$;
$\triangleright$ then the fire starting at $\left(S_{3}, Y_{3}\right)$ can not affect $[0, B]$, because since $S_{3} \in\left[S_{2}, S_{2}+\frac{1}{4}\right), H_{S_{3}-}\left(Y_{2}\right)>0$ or $Z_{S_{3}-}\left(Y_{2}\right)>0$, with $Y_{3}<Y_{2}<0$;
$\triangleright$ then the fire starting at $\left(S_{4}, Y_{4}\right)$ can not affect $[0, B]$, because since $S_{4} \in\left[S_{3}, S_{3}+\frac{1}{4}\right), H_{S_{4}-}\left(Y_{3}\right)>0$ or $Z_{S_{4}-}\left(Y_{3}\right)>0$, with $Y_{4}<Y_{3}<0$;
$\triangleright$ then the fire starting at $\left(S_{5}, Y_{5}\right)$ can not affect $[0, B]$, because since $S_{5} \in\left[S_{4}, S_{4}+\frac{1}{4}\right), H_{S_{5}-}\left(Y_{4}\right)>0$ or $Z_{S_{5}-}\left(Y_{4}\right)>0$, with $Y_{5}<Y_{4}<0 ;$
$\triangleright$ furthermore, the fires starting on the left at -1 during ( $\left.S_{1}, t\right]$ cannot affect $[0, B]$, because for all $t \in\left(S_{1}, t\right]$, there is always a site $x_{t} \in\left\{Y_{1}, Y_{2}, Y_{3}, Y_{4}\right\} \subset$ $[-1,0]$ with $H_{t}\left(x_{t}\right)>0$ or $Z_{t}\left(x_{t}\right)<1$;
$\triangleright$ the same arguments apply on the right of $B$.
As a conclusion, the zone $[0, B]$ is not affected by any fire during $\left(S_{1} \vee \widetilde{S}_{1}, t\right]$. Since the length of this time interval is greater than 1 , we deduce that for all $x \in[0, B]$,

$$
\begin{aligned}
& Z_{t}(x)=\min \left(Z_{S_{1} \vee \widetilde{S}_{1}}(x)+t-S_{1} \vee \widetilde{S}_{1}, 1\right) \geq \min \left(t-S_{1} \vee \widetilde{S}_{1}, 1\right)=1 \\
& H_{t}(x)=\max \left(H_{S_{1} \vee \widetilde{S}_{1}}(x)-\left(t-S_{1} \vee \widetilde{S}_{1}\right), 0\right) \leq \max \left(1-\left(t-S_{1} \vee \widetilde{S}_{1}\right), 0\right)=0
\end{aligned}
$$

whence $[0, B] \subset D_{t}(0)$.
Point (v). - For $0 \leq a<b<1$ and $t \geq 1$, we have $Z_{t}(0) \in[a, b]$ if and only there is $\tau \in[t-b, t-a]$ such that $Z_{\tau}(0)=0$. And this happens if and only if

$$
X_{t, a, b}:=\int_{t-b}^{t-a} \int_{\mathbb{R}} \mathbb{1}_{\left\{y \in D_{s-}(0)\right\}} \pi_{M}(\mathrm{~d} s, \mathrm{~d} y) \geq 1
$$

We deduce that

$$
\operatorname{Pr}\left(Z_{t}(0) \in[a, b]\right)=\operatorname{Pr}\left(X_{t, a, b} \geq 1\right) \leq \mathbb{E}\left[X_{t, a, b}\right]=\int_{t-b}^{t-a} \mathbb{E}\left[\left|D_{s}(0)\right|\right] \mathrm{d} s \leq C(b-a),
$$

where we used point (iii) for the last inequality.
Next, we have $\left\{\pi_{M}\left([t-b, t-a] \times D_{t-b}(0)\right) \geq 1\right\} \subset\left\{X_{t, a, b} \geq 1\right\}$ : it suffices to note that a.s.,

$$
\begin{aligned}
\left\{X_{t, a, b}=0\right\} & \subset\left\{X_{t, a, b}=0, D_{t-b}(0) \subset D_{s}(0) \text { for all } s \in[t-b, t-a]\right\} \\
& \subset\left\{\pi_{M}\left([t-b, t-a] \times D_{t-b}(0)\right)=0\right\} .
\end{aligned}
$$

Now since $D_{t-b}(0)$ is independent of $\pi_{M}(\mathrm{~d} s, \mathrm{~d} x)$ restricted to $(t-b, \infty) \times \mathbb{R}$, we deduce that for $t \geq \frac{5}{2}$

$$
\begin{aligned}
\operatorname{Pr}\left(Z_{t}(0) \in[a, b]\right) & \geq \operatorname{Pr}\left[\pi_{M}\left((t-b, t-a] \times D_{t-b}(0)\right) \geq 1\right] \\
& \geq \operatorname{Pr}\left[\left|D_{t-b}(0)\right| \geq 1\right]\left(1-\mathrm{e}^{-(b-a)}\right) \geq c\left(1-\mathrm{e}^{-(b-a)}\right),
\end{aligned}
$$

where we used point (iv) (here $t-b \geq \frac{3}{2}$ ) to get the last inequality. This concludes the proof, since $1-\mathrm{e}^{-x} \geq \frac{1}{2} x$ for all $x \in[0,1]$.
3.11.2. The case $\beta=\infty$. - We can now handle the

Proof of Corollary 2.3.4. - We thus assume $\left(H_{M}\right)$ and $\left(H_{S}(\infty)\right)$ and consider, for each $\lambda>0, \operatorname{aFF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. Let also $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ be a $\operatorname{LFF}(\infty)$-process.

Point (ii). - Using Lemma 3.11 .1 (iii)-(iv) and recalling that

$$
\left|C\left(\eta_{\boldsymbol{a}_{\lambda} t}^{\lambda}, 0\right)\right| / \boldsymbol{n}_{\lambda}=\left|D_{t}^{\lambda}(0)\right|
$$

by (2.2.3), it suffices to check that for all $t \geq \frac{3}{2}$, all $B>0$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|D_{t}^{\lambda}(0)\right| \geq B\right]=\operatorname{Pr}\left[\left|D_{t}(0)\right| \geq B\right]
$$

This follows from Theorem 2.3.3 (b), which implies that $\left|D_{t}^{\lambda}(0)\right|$ goes in law to $\left|D_{t}(0)\right|$ and from Lemma 3.11.1 (ii).

Point (i). - Due to Lemma 3.11.1 (v) we only need that for all $0<a<b<1$, all $t \geq \frac{5}{2}$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left(\left|C\left(\eta_{a_{\lambda} t}^{\lambda}, 0\right)\right| \in\left[1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} a, \infty\right)\right), 1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda} b, \infty\right)\right)\right]\right)=\operatorname{Pr}\left(Z_{t}(0) \in[a, b]\right)
$$

But using Theorem 2.3.3 (c) and Lemma 3.11.1 (i), we know that

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\psi_{S}\left(1-1 /\left|C\left(\eta_{a_{\lambda} t}^{\lambda}, 0\right)\right|\right) \mathbb{1}_{\left\{\left|C\left(\eta_{\boldsymbol{a}_{\lambda}}^{\lambda}, 0\right)\right| \geq 1\right\}} \in\left[\boldsymbol{a}_{\lambda} a, \boldsymbol{a}_{\lambda} b\right]\right]=\operatorname{Pr}\left(Z_{t}(0) \in[a, b]\right)
$$

Using finally the definition of $\psi_{S}$ (see notation 2.1.5 (ii)), we see that for all $c \in \mathbb{N}$, all $0<\alpha<\beta$,

$$
\psi_{S}(1-1 / c) \mathbb{1}_{\{c \geq 1\}} \in[\alpha, \beta] \text { if and only if } c \in\left[1 / \nu_{S}((\alpha, \infty)), 1 / \nu_{S}((\beta, \infty))\right]
$$

One immediately concludes.
3.11.3. The case $\beta=B S$. - We finally give the

Proof of Corollary 2.4.5. - We thus assume $\left(H_{M}\right)$ and $\left(H_{S}(B S)\right)$ and consider, for each $\lambda>0, \operatorname{aFF}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$-process $\left(\eta_{t}^{\lambda}(i)\right)_{t \geq 0, i \in \mathbb{Z}}$. Let also $\left(Z_{t}(x), D_{t}(x), H_{t}(x)\right)_{t \geq 0, x \in \mathbb{R}}$ be a $\operatorname{LFF}(B S)$-process.

Point (ii). - Using Lemma 3.11 .1 (iii)-(iv) and recalling that

$$
\left|C\left(\eta_{a_{\lambda} t}^{\lambda}, 0\right)\right| / \boldsymbol{n}_{\lambda}=\left|D_{t}^{\lambda}(0)\right|
$$

by (2.2.3), it suffices to check that for all $t \geq \frac{3}{2}$, all $B>0$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|D_{t}^{\lambda}(0)\right| \geq B\right]=\operatorname{Pr}\left[\left|D_{t}(0)\right| \geq B\right]
$$

This follows from Theorem 2.4.4 (b), which implies that $\left|D_{t}^{\lambda}(0)\right|$ goes in law to $\left|D_{t}(0)\right|$ and from Lemma 3.11.1 (ii).

Point (i). - Theorem 2.4.4(c) asserts that for all $t \geq 0$, all $k \geq 0$,

$$
\lim _{\lambda \rightarrow 0} \operatorname{Pr}\left[\left|C\left(\eta_{T_{S} t}^{\lambda}, 0\right)\right|=k\right]=\mathbb{E}\left[q_{k}\left(Z_{t}(0)\right)\right]
$$

where $q_{k}(z)$ was defined in (2.4.2). Using next Lemma 3.11.1 (v) and recalling that $Z_{t}(0) \in[0,1]$ a.s., we see that for $t \geq \frac{5}{2}$, the law of $Z_{t}(0)$ is of the form

$$
g_{t}(z) \mathbb{1}_{\{0 \leq z \leq 1\}} \mathrm{d} z+\alpha_{t} \delta_{1}(\mathrm{~d} z),
$$

for some function $g_{t}:[0,1] \mapsto \mathbb{R}_{+}$satisfying $c \leq g_{t} \leq C$, where the constants $0<c<C$ do not depend on $t \geq \frac{5}{2}$. One immediately deduces that for any $k \geq 0$, $\mathbb{E}\left[q_{k}\left(Z_{t}(0)\right)\right] \in\left[c q_{k}, C q_{k}\right]$. Indeed, there holds $q_{k}=\int_{0}^{1} q_{k}(z) \mathrm{d} z$ and $q_{k}(1)=0$. This concludes the proof.

## CHAPTER 4

## NUMERICAL SIMULATIONS

### 4.1. Simulations

We would like to present some simulations of the discrete forest fire process. In all the simulations below, we choose $\mu_{M}^{\lambda}(\mathrm{d} t)=\lambda \mathrm{e}^{-\lambda t} \mathbb{1}_{t \geq 0} \mathrm{~d} t$ and we consider different laws $\mu_{S}$. We simulate the $\mathrm{FF}_{A}\left(\mu_{S}, \mu_{M}^{\lambda}\right)$ process with $A=2.5$, for some given value of $\lambda$. Since there are too much concerned sites, it is not possible to draw the whole picture. We thus extract a zone in which some interesting events occur.

In all the pictures below, time evolves vertically, with $t=0$ at the bottom. On each site, we plot white (resp. black) segments when the site is vacant (resp. occupied). Matches are represented by bullets.

Figure 10. Simulation with $\beta=B S$.

We used $\mu_{S}=\delta_{1}, \nu_{S}(\mathrm{~d} t)=1_{\{t \in[0,1]\}} \mathrm{d} t, \boldsymbol{a}_{\lambda}=T_{S}=1$ and $\lambda=10^{-3}$. Here everything happens, roughly, as described by the limit process (compare with Figure 3).

At the begining, all the sites are vacant. Many sites remain vacant for a while, but we observe that all become occupied after some time, except one, which has burnt due to the first match.

This first match produces a microscopic fire, involving very few sites (we cannot see it on the picture because the bullet is slightly too large, but these sites were occupied just before the match).

The second fire is macroscopic: it concerns many sites. It it is limited on the right by a vacant site, which is due to the effect of the first (microscopic) fire.

The third fire concerns few sites and is microscopic.
The fourth fire is macroscopic and is limited on the left by the a vacant site, produced by the second fire (which was macroscopic and destroyed a large zone which is not filled again).

The fifth fire is macroscopic and is limited by a vacant site produced by the third fire, which was microscopic.

Finally, the last fire is macroscopic, and is limited on both sides by vacant sites let by the two previous (macroscopic) fires.

Observe that the time needed to completely fill again a macroscopic zone is roughly always the same (look at the time needed after time 0 , after the second fire, after the fourth fire).

Note also that the effect of the first (microscopic) fire persists for quite a long time: it limits the second fire, which limits the fourth fire, which itself limits the sixth fire.

Figure 11. Simulation with $\beta=\infty$.

Here $\mu_{S}((t, \infty))=\mathrm{e}^{-t^{2} / 2}, \nu_{S}(\mathrm{~d} t)=(\sqrt{2 / \pi}) \mathrm{e}^{-t^{2} / 2} 1_{\{t \geq 0\}} \mathrm{d} t$ and $\lambda=10^{-3}$. We used the approximate value $a_{\lambda} \simeq \sqrt{2 \log (1 / \lambda)}$. The picture is not so far from the limit process (compare with Figure 2), but there are some defaults.

The first fire is rather microscopic, but has however quite a large length.
The second fire, which is clearly macroscopic, is limited not by a previous microscopic fire, but by a site where the first seed has needed an unusual large time to fall.

Also, the limit process predicts that the length of the barrier produced by a microscopic fire equals the delay between the time at which the match falls and the last time where the zone was involved in a maroscopic fire. We see here that this is roughly the case for the first fire, but the effect of the third and fourth (microscopic) fires are too long.

Figure 12. Simulation with $\beta=5$.

We considered $\mu_{S}((t, \infty))=(1+t / \beta)^{-\beta-1}$ and $\nu_{S}((t, \infty))=(1+t / \beta)^{-\beta}$ with $\beta=5$ and $\lambda=5.10^{-3}$. We used the approximate value $a_{\lambda} \simeq(1 / \lambda)^{1 /(\beta+1)}$. This picture resembles much the limit process (see Figure 4): all the fires involve a macroscopic number of sites and we observe that sites where no seed fall during a large time interval are rather rare.

Figure 13. Simulation with $\beta=2$.

Same thing as Figure 12 with $\beta=2$ and $\lambda=10^{-3}$. This picture is in perfect adequacy with the limit process (see Figure 4), at least from a qualitative point of view: when a fire starts, it burns a macroscopic zone, which is rather quickly filled again, except for some quite rare sites.

Figure 14. Simulation with $\beta=0$.
We used $\mu_{S}((t, \infty))=e(e+t)^{-1}[\log (e+t)]^{-2}, \nu_{S}((t, \infty))=[\log (e+t)]^{-1}$ and $\lambda=10^{-7}$. We used the approximate value $a_{\lambda} \simeq 1 /[\lambda \log (1 / \lambda)]$. This picture is quite satisfactory when compared to the limit process (see Figure 5): there are six sites where the first seed never falls and the fires have quite a low effect, in the sense that most of the burnt sites become occupied again almost immediately.

## CHAPTER 5

## APPENDIX

### 5.1. Appendix

5.1.1. Regularly varying functions. - The proof below is closely related to the theory of regularly varying functions and is probably completely standard.

Lemma 5.1.1. - Assume $\left(H_{S}\right)$. Then either $\left(H_{S}(B S)\right)$ holds or there exists $\beta$ in $[0, \infty) \cup\{\infty\}$ such that $\left(H_{S}(\beta)\right)$ holds.

Proof. - We thus assume $\left(H_{S}\right)$ and that the support of $\mu_{S}$ is unbounded. Hence, for all $t>0$,

$$
\varphi(t):=\lim _{x \rightarrow \infty} \frac{\nu_{S}((x, \infty))}{\nu_{S}((x t, \infty))} \in[0, \infty) \cup\{\infty\}
$$

exists. The function $\varphi$ is clearly nondecreasing and satisfies $\varphi(1)=1$.
Step 1. - We first show that for all $t>0, \varphi(1 / t)=1 / \varphi(t)$, with the convention that $1 / 0=\infty$ and $1 / \infty=0$. This is not hard:

$$
\varphi(1 / t)=\lim _{x \rightarrow \infty} \frac{\nu_{S}((x, \infty))}{\nu_{S}((x / t, \infty))}=\lim _{y \rightarrow \infty} \frac{\nu_{S}((y t, \infty))}{\nu_{S}((y, \infty))}=1 / \varphi(t) .
$$

Step 2. - By the same way, one easily checks that for $0<s \leq t$, one has $\varphi(s t)=\varphi(s) \varphi(t)$ as soon as $\varphi(s)>0$ or $\varphi(t)<\infty$. It suffices to write

$$
\varphi(s t)=\lim _{x \rightarrow \infty} \frac{\nu_{S}((x, \infty))}{\nu_{S}((x s t, \infty))}=\lim _{x \rightarrow \infty} \frac{\nu_{S}((x, \infty))}{\nu_{S}((x s, \infty))} \frac{\nu_{S}((x s, \infty))}{\nu_{S}((x s t, \infty))}=\varphi(s) \varphi(t) .
$$

Step 3. - We assume first that $\varphi(s)>0$ for all $s \in(0,1)$. By Step 1, one easily deduces that $\varphi(s) \in(0, \infty)$ for all $s>0$. We thus have a nondecreasing function $\varphi:(0, \infty) \mapsto(0, \infty)$ such that $\varphi(s t)=\varphi(s) \varphi(t)$ for all $0<s \leq t$ and such that $\varphi(1)=1$. One classically concludes that there exists $\beta \in[0, \infty)$ such that $\varphi(t)=t^{\beta}$.

Step 4. - We now assume that $\varphi(\alpha)=0$ for some $\alpha \in(0,1)$. We want to show that if so, then $\varphi(t)=0$ for all $t \in(0,1)$. This will imply that $\varphi(t)=\infty$ for $t>1$ by step 1 , whence $\varphi(t)=t^{\infty}$.

Let thus $\alpha_{*}=\sup \{\alpha>0: \varphi(\alpha)=0\}$. Suppose by contradiction that $\alpha_{*} \in(0,1)$. By monotonicity, we have $\varphi(\alpha)=0$ for all $\alpha \in\left(0, \alpha_{*}\right)$. By step 1 , we know that $\varphi(s) \in(0, \infty)$ for all $s \in\left(\alpha_{*}, 1 / \alpha_{*}\right)$. Due to step 2, we deduce that for all small $\varepsilon>0$, $\varphi\left(\left(\alpha_{*}-\varepsilon\right)\left(1 / \alpha_{*}-\varepsilon\right)\right)=0$. But for $\varepsilon>0$ small enough, we have $\left(\alpha_{*}-\varepsilon\right)\left(1 / \alpha_{*}-\varepsilon\right)>\alpha_{*}$ (because $\alpha_{*}<1$ ). This contradicts the definition of $\alpha_{*}$.

Next, we prove the existence of the scale $\boldsymbol{m}_{\lambda}$ satisfying (2.2.4).
Lemma 5.1.2. - Assume $\left(H_{S}(\infty)\right)$. Recall (2.2.1), (2.2.2). There exists a function $\boldsymbol{m}_{\lambda}:(0,1] \mapsto \mathbb{N}$ satisfying (2.2.4).

Proof. - Recalling that $\lim _{\lambda \rightarrow 0} \boldsymbol{a}_{\lambda}=\infty$ and using $\left(H_{S}(\infty)\right)$, we observe that for any $n \geq 1$,

$$
\lim _{\lambda \rightarrow 0} \nu_{S}\left(\left((1-1 / n) \boldsymbol{a}_{\lambda}, \infty\right)\right) / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)=\infty
$$

Thus there exists $\lambda_{n} \in(0,1]$ such that for all $\lambda \in\left(0, \lambda_{n}\right]$,

$$
\nu_{S}\left(\left((1-1 / n) \boldsymbol{a}_{\lambda}, \infty\right)\right) / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right) \geq n
$$

We of course may choose $\lambda_{1}=1$ and choose the sequence $\left(\lambda_{n}\right)_{n \geq 1}$ decreasing to 0 . Then we define $\varepsilon_{\lambda}:(0,1] \mapsto(0,1]$ by setting, for all $n \geq 1, \varepsilon_{\lambda}=1 / n$ for $\lambda \in\left(\lambda_{n+1}, \lambda_{n}\right]$. There holds $\lim _{\lambda \rightarrow 0} \varepsilon_{\lambda}=0$. Finally, we put

$$
\boldsymbol{m}_{\lambda}=\left\lfloor 1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}\left(1-\varepsilon_{\lambda}\right), \infty\right)\right)\right\rfloor .
$$

This function is obviously non-increasing. Next, recalling that $\boldsymbol{n}_{\lambda}=\left\lfloor 1 / \nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)\right\rfloor$, we see that for all $n \geq 1$, all $\lambda \in\left(\lambda_{n+1}, \lambda_{n}\right)$,

$$
\frac{\boldsymbol{m}_{\lambda}}{\boldsymbol{n}_{\lambda}} \simeq \frac{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)}{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}\left(1-\varepsilon_{\lambda}\right), \infty\right)\right)}=\frac{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}, \infty\right)\right)}{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}(1-1 / n), \infty\right)\right)} \leq \frac{1}{n},
$$

whence $\lim _{\lambda \rightarrow 0}\left(\boldsymbol{m}_{\lambda} / \boldsymbol{n}_{\lambda}\right)=0$. Finally, fix $z \in(0,1)$ and consider $n$ large enough, so that $1-1 / n>z$. Then for $\lambda \in\left(0, \lambda_{n}\right)$, there holds $\varepsilon_{\lambda} \leq 1 / n$, whence

$$
\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} z, \infty\right)\right) \boldsymbol{m}_{\lambda} \simeq \frac{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} z, \infty\right)\right)}{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}\left(1-\varepsilon_{\lambda}\right), \infty\right)\right)} \geq \frac{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda} z, \infty\right)\right)}{\nu_{S}\left(\left(\boldsymbol{a}_{\lambda}(1-1 / n), \infty\right)\right)} \rightarrow \infty
$$

as $\lambda \rightarrow 0$ due to $\left(H_{S}(\infty)\right)$, since $z<1-1 / n$.
5.1.2. Coupling. - Finally, we recall some well-known facts about coupling.

Lemma 5.1.3. - (i) Let $\left(p_{k}\right)_{k \geq 0}$ and $\left(q_{k}\right)_{k \geq 0}$ be two probability laws on $\{0,1, \ldots\}$.
One can couple

$$
X \sim\left(p_{k}\right)_{k \geq 0} \quad \text { and } \quad Y \sim\left(q_{k}\right)_{k \geq 0}
$$

such that for all $k \geq 0$,

$$
\operatorname{Pr}[X=Y=k] \geq p_{k} \wedge q_{k}
$$

(ii) For $f$, g two probability densities on $\mathbb{R}$, one can couple $X \sim f(x) \mathrm{d} x$ and $Y \sim$ $g(x) \mathrm{d} x$ in such a way that

$$
\operatorname{Pr}[X=Y] \geq \int_{\mathbb{R}} \min (f(x), g(x)) \mathrm{d} x
$$

(iii) If we have a sequence of laws $\mu_{n}$ on some Polish space, converging weakly to some law $\mu$, then it is possible to find some random variables $X_{n} \sim \mu_{n}$ and $X \sim \mu$ such that a.s., $\lim _{n \rightarrow \infty} X_{n}=X$.

Proof. - First observe that (iii) is nothing but the Skorokhod representation theorem. To prove (i), set $r_{k}=p_{k} \wedge q_{k}$ and $r=\sum_{0}^{\infty} r_{k}$. Consider a Bernoulli r.v. $C$ with parameter $r$, a $\left(r_{k} / r\right)_{k \geq 0}$-distributed r.v. $Z$, a $\left(\left(p_{k}-r_{k}\right) /(1-r)\right)_{k \geq 0}$-distributed r.v. $U$ and a $\left(\left(q_{k}-r_{k}\right) /(1-r)\right)_{k \geq 0}$-distributed r.v. $V$. Assume that all these objects are independent and put $(X, Y)=C(Z, Z)+(1-C)(U, V)$. Some immediate computations show that $X \sim\left(p_{k}\right)_{k \geq 0}$ and $Y \sim\left(q_{k}\right)_{k \geq 0}$ and for $k \geq 0, \operatorname{Pr}[X=Y=k] \geq r_{k}$.

The proof of (ii) is similar: put $h=\min (f, g)$ and $r=\int_{\mathbb{R}} h(x) \mathrm{d} x$. Consider a Bernoulli r.v. $C$ with parameter $r$, a r.v. $Z$ with density $h / r$, a r.v. $U$ with density $(f-h) /(1-r)$ and a r.v. $V$ with density $(g-h) /(1-r)$. Assume that all these objects are independent and put $(X, Y)=C(Z, Z)+(1-C)(U, V)$. Some immediate computations show that $X \sim f(x) \mathrm{d} x, Y \sim g(y) \mathrm{d} y$ and $\operatorname{Pr}[X=Y] \geq r$.
