# Area-minimizing integral currents with movable boundary parts of prescribed mass 

by<br>Klaus ECKER<br>Department of Mathematics,<br>University of Melbourne, Parkville Vic. 3052, Australia

Abstract. - We generalize the thread problem for minimal surfaces to higher dimensions using the framework of integral currents.

Key words : Integral currents, minimizing area, minimal surface, free boundary, mass.
Résumé. - On généralise le «problème fil» pour surfaces minimales aux dimensions plus hautes en utilisant le cadre de courants intégrals.

## 0. INTRODUCTION

The classical thread problem for minimal surfaces in $\mathbb{R}^{3}$ can be formulated as follows: For a given rectifiable Jordan arc $\Gamma$ and a movable arc $\Sigma$ of fixed length attached to the endpoints of $\Gamma$ one wants to find a surface $\mathscr{M}$ of least area among all surfaces spanning this configuration.

[^0]For a detailed description of the problem and a list of relevant literature on related soap-film experiments we refer the reader to the recent paper by Dierkes, Hildebrandt and Lewy [DHL].

One can easily construct examples where the thread $\Sigma$ "crosses" the wire $\Gamma$ (for planar " S "-shaped $\Gamma$ ) or "sticks" to it in a subarc of positive length (if for instance $\Gamma$ has the shape of a long " $U$ "). In other words, the solution surface $\mathscr{M}$ may consist of several disconnected components and there may be parts of $\Sigma$ and $\Gamma$ which do not belong to $\partial \mathscr{M}$. In fact this represents the main difficulty for the existence proof, at least in the parametric approach of [AHW], [N1]-[N3] and [DHL].

Nitsche ([N1]-[N3]) proved that the nonselfintersecting components of $\Sigma \sim \Gamma$ are actually smooth arcs of constant curvature. Dierkes, Hildebrandt and Lewy [DHL] established the real analyticity of these arcs.

Alt [AHW] was able to prove that the parts of $\Sigma$ which attach to regular parts of $\Gamma$ in subarcs of positive length have to do this tangentially. Moreover he could show, if a solution surface consists of several disconnected components, all regular parts of $\Sigma \sim \Gamma$ necessarily have the same curvature.

The present work is concerned with a more general approach to the thread problem which, due to its generality in handling the existence problem, does not enable one to determine a priori the topological type of the solution surfaces as was done by Alt [AHW] in his existence proof.

For a start we would like to allow $\Gamma$ to be disconnected. $\Gamma$ may for instance consist of several oriented arcs or even closed curves. A suitable generalization of the classical problem would then be to seek a surface $\mathscr{M}$ of minimal area among all oriented surfaces $\mathscr{S}$ such that $\partial \mathscr{S}-\Gamma$ is prescribed, where in subtracting $\Gamma$ form $\partial \mathscr{S}$ we take orientations into account. If $\Gamma$ consists of several wire arcs we do not prescribe the way in which our threads have to be connected to the endpoints of $\Gamma$. Also, rather than prescribing the length of each single piece of thread, we only keep the total length of $\Sigma=\partial \mathscr{M}-\Gamma$ fixed. As there is no obvious way of excluding the possibility of $\Sigma$ having higher multiplicity we may as well allow $\Gamma$ to have arbitrary integer multiplicity.

In section 1 we give a precise formulation of the problem for arbitrary dimension and codimension using the framework of integral currents. We then solve the existence problem (Theorem 1.4).

Section 2 is concerned with properties of the thread related to the above mentioned results ([AHW], [DHL], [N1]-[N3]). We generalize the Lagrange multiplier techniques used in [DHL] to obtain control of the first variation of $\Sigma$ (Theorem 2.3 and Corollary 2.5). In fact we show that $\Sigma$ has bounded generalized mean curvature away from its boundary $\partial \Sigma$. This implies in particular that $\Sigma$ only coincides with parts of $\Gamma$ which have bounded generalized mean curvature. Moreover this establishes a weak tangential property of $\Sigma$ at points on $\Gamma$.

Proposition 2.7 states that all free regular parts of $\Sigma$ are of class $\mathbf{C}^{\infty}$ and have the same constant mean curvature and that, in constrast to the higher multiplicity Plateau problem (cf. [WB]), a thread with higher integer multiplicity cannot locally bound several distinct sheets of minimal surfaces unless the thread itself has zero mean curvature. By "free parts" of $\Sigma$ we not only mean $\Sigma \sim \Gamma$ but also those sections of $\Sigma$ supported in $\Gamma$ where the multiplicity of $\partial \mathscr{M}$ is not smaller than the multiplicity of $\Gamma$. A simple example where a "free" $\Sigma$ is supported in $\Gamma$ is obtained by letting $\mathscr{M}$ be an oriented annulus with multiplicity two, and $\Sigma$ be the inner circle counted with multiplicity one.
If however locally near a point of $\Sigma$

$$
\partial \mathscr{M}=c \Gamma
$$

for some $c \in[0,1)$, the mean curvature of $\Sigma$ need no longer be constant. Nevertheless it cannot exceed the mean curvature of the free parts of $\Sigma$.

As Theorem 2.3 holds without any major conditions imposed on $\Gamma$ one can show that also the decomposable components of any local decomposition of $\Sigma$ have bounded generalized mean curvature. This leads to some partial regularity results for the two dimensional thread problem: Theorem 3.1 states that one dimensional stationary threads consist of straightline segments which do not intersect, thus suggesting a natural condition for the existence of a Lagrange multiplier as in Theorem 2.3.
In Theorem 3.3 we show that the thread $\Sigma$ consists of $C^{1,1}$-arcs which do not cross each other. If several pieces of thread have a point in common they must have the same tangent at this point. It is tempting to conjecture that one dimensional threads are completely regular.

Finally we derive a monotonicity formula for the two dimensional problem, from which the existence of area-minimizing tangent cones immediately follows.

We would like to thank Prof. S. Hildebrandt for directing our attention to this problem.

## 1. THE VARIATIONAL PROBLEM

For detailed information on geometric measure theory the reader is referred to [FH] and [SL]. We shall follow the notation used in [SL].

Let $U$ be an open subset of $\mathbb{R}^{n+k}$. We denote the class of $n$-dimensional integral currents in $U$ by

$$
\mathrm{I}_{n, \text { loc }}(\mathrm{U})=\left\{\mathrm{S} \in \mathscr{D}_{n}(\mathrm{U}) / \mathrm{S}, \partial \mathrm{~S} \text { integer multiplicity }\right\}
$$

and

$$
\mathbf{I}_{n}(\mathrm{U})=\left\{\mathbf{S} \in \mathbf{I}_{n, \text { loc }}(\mathbf{U}) / \mathbf{M}(\mathbf{S})+\mathbf{M}(\partial \mathbf{S})<\infty\right\}
$$

### 1.1. Definition

$\mathrm{T} \in \mathrm{I}_{n, \text { loc }}(\mathrm{U})$ is called a minimizer of the thread problem with respect to $\Gamma \in \mathrm{I}_{n-1, \text { loc }}$ (U) if

$$
\mathbf{M}_{\mathbf{w}}(\mathrm{T}) \leqq \mathbf{M}_{\mathbf{w}}(\mathbf{S})
$$

whenever $\mathrm{W} \subset \mathrm{U}$ is open and $\mathrm{S} \in \mathrm{I}_{n, \text { loc }}(\mathrm{U})$ satisfies

$$
\operatorname{spt}(S-T) \subset \mathbf{W}
$$

as well as

$$
\mathbf{M}_{\mathbf{w}}(\partial \mathbf{S}-\Gamma)=\mathbf{M}_{\mathbf{w}}(\partial \mathrm{T}-\Gamma) .
$$

### 1.2. Remark

(1) We shall sometimes refer to $\Sigma=\partial \mathrm{T}-\Gamma$ as the free or thread-boundary part and to $\Gamma$ as the fixed or wire-boundary part of T although neither $\operatorname{spt} \Sigma$ nor $\operatorname{spt} \Gamma$ has to be totally contained in spt $\partial \mathrm{T}$; in fact we may have

$$
\mu_{\Sigma}(\operatorname{spt} \Gamma \sim \operatorname{spt} \partial T)>0
$$

(2) A minimizer T of the thread problem obviously minimizes mass also in the usual sense, that is among all comparison surfaces which agree with T along its boundary $\partial \mathrm{T}$.

### 1.3. Proposition

A minimizer in the sense of 1.1 still satisfies

$$
\mathbf{M}_{\mathbf{w}}(\mathrm{T}) \leqq \mathbf{M}_{\mathbf{w}}(\mathbf{S})
$$

even if we only assume that the inequality

$$
\mathbf{M}_{\mathbf{w}}(\partial \mathbf{S}-\Gamma) \leqq \mathbf{M}_{\mathbf{w}}(\partial \mathrm{T}-\Gamma)
$$

holds for surfaces $\mathrm{S} \in \mathrm{I}_{n, \text { loc }}(\mathrm{U})$ satisfying $\operatorname{spt}(\mathrm{S}-\mathrm{T}) \subset \mathrm{W}$.
Proof. - Suppose there exists an $\mathrm{R} \in \mathrm{I}_{n \text {, loc }}(\mathrm{U})$ which satisfies $\operatorname{spt}(\mathrm{R}-\mathrm{T}) \subset \mathbf{W}$,

$$
\mathbf{M}_{\mathbf{w}}(\partial \mathbf{R}-\Gamma)<\mathbf{M}_{\mathbf{w}}(\partial \mathrm{T}-\Gamma)
$$

and

$$
\mathbf{M}_{\mathbf{w}}(\mathbf{R})<\mathbf{M}_{\mathbf{w}}(\mathrm{T}) .
$$

Obviously we can always find an integral current $Q \in I_{n}(W)$ such that spt $\mathrm{Q} \cap(\mathrm{spt} \mathrm{R} \cup \operatorname{spt} \Gamma)=\varnothing, \operatorname{spt} \mathrm{Q} \subset \mathbf{W}$,

$$
\mathbf{M}_{\mathbf{w}}(\mathrm{Q})<\mathbf{M}_{\mathbf{w}}(\mathbf{T})-\mathbf{M}_{\mathbf{w}}(\mathrm{R})
$$

and

$$
\mathbf{M}_{\mathbf{w}}(\partial \mathbf{Q})=\mathbf{M}_{\mathbf{w}}(\partial \mathrm{T}-\Gamma)-\mathbf{M}_{\mathbf{w}}(\partial \mathbf{R}-\Gamma) .
$$

$R+Q$ then furnishes an admissible comparison surface in the sense of 1.1 with the property

$$
\mathbf{M}_{\mathbf{w}}(\mathrm{R}+\mathrm{Q})<\mathbf{M}_{\mathbf{w}}(\mathrm{T})
$$

thus contradicting the minimality of $T$.
We are now going to establish the existence of a nontrivial minimizer.
Let $\Gamma \in I_{n-1}\left(\mathbb{R}^{n+k}\right)$ have compact support. Define

$$
d_{\Gamma}=\inf \left\{\mathbf{M}(\mathrm{Q}) / \mathrm{Q} \in \mathrm{I}_{n-1}\left(\mathbb{R}^{n+k}\right) \text { s. t. } \partial \mathrm{Q}=\partial \Gamma\right\}
$$

and suppose $\mathbf{M}(\Gamma)>d_{\Gamma}$.

### 1.4. Theorem

Let $d_{\Gamma} \leqq \mathrm{L}<\mathbf{M}(\Gamma)$. Then there exists a nontrivial compactly supported surface $T \in I_{n}\left(\mathbb{R}^{n+k}\right)$ which minimizes mass among all surfaces $S \in I_{n}\left(\mathbb{R}^{n+k}\right)$ with the property $\mathbf{M}(\partial \mathbf{S}-\Gamma)=\mathrm{L}$.

### 1.5. Remark

Every minimizer of 1.4 also minimizes mass in the sense of Definition 1.1.

Proof of 1.4. We set

$$
\mathrm{A}(\Gamma, \mathrm{~L})=\left\{\mathrm{S} \in \mathrm{I}_{n}\left(\mathbb{R}^{n+k}\right) / \mathbf{M}(\partial \mathrm{S}-\Gamma) \leqq \mathrm{L}\right\} .
$$

Obviously $L<\mathbf{M}(\Gamma)$ implies $0 \notin A(\Gamma, L)$. Since $\mathbf{M}(\Gamma)>d_{\Gamma}$ there exists a compactly supported $Q \in I_{n-1}\left(\mathbb{R}^{n+k}\right)$ which is different from $\Gamma$ and satisfies $\partial \mathrm{Q}=\partial \Gamma$ as well as $\mathbf{M}(\mathrm{Q})=d_{\Gamma}$. (Use [SL], 34.1 for instance.) The integral cone $\mathrm{R}=0$ \# $(\Gamma-\mathrm{Q})$ then satisfies $\mathbf{M}(\partial \mathbf{R}-\Gamma)=\mathbf{M}(\mathrm{Q})=d_{\Gamma}$. From $d_{\Gamma} \leqq \mathrm{L}$ we conclude that $\mathbf{A}(\Gamma, \mathrm{L})$ is nonempty.

We now proceed in a similar way as in [SL, 34.1]. Let $\left(T_{j}\right) \subset A(\Gamma, L)$, $j \geqq 1$, be a minimizing sequence, that is

$$
\lim _{j \rightarrow \infty} \mathbf{M}\left(\mathbf{T}_{j}\right)=\inf \{\mathbf{M}(\mathbf{S}) / \mathbf{S} \in \mathbf{A}(\Gamma, \mathrm{L})\} .
$$

Since $\Gamma$ has compact support we may assume that $\operatorname{spt} \Gamma \subset B_{R}(0)$ for some $R>0$, where $B_{R}(0)$ denotes an open ball in $\mathbb{R}^{n+k}$. Let $f: \mathbb{R}^{n+k} \rightarrow \overline{\mathbf{B}_{\mathbf{R}}(0)}$ be the nearest point retraction form $\mathbb{R}^{n+k}$ onto $\overline{\mathbf{B}_{\mathbf{R}}(0)}$. It follows from the fact that $\operatorname{Lip} f=1$ and $f=\mathrm{id}$ in $\overline{\mathbf{B}_{\mathrm{R}}(0)}$ that

$$
\begin{gathered}
\mathbf{M}\left(f_{\sharp} \mathbf{T}_{j}\right) \leqq \mathbf{M}\left(\mathrm{T}_{j}\right) \\
\mathbf{M}\left(\partial f_{\sharp} \mathrm{T}_{j}-\Gamma\right)=\mathbf{M}\left(f_{\sharp}\left(\partial \mathrm{T}_{j}-\Gamma\right)\right) \leqq \mathbf{M}\left(\partial \mathrm{T}_{j}-\Gamma\right) \leqq \mathrm{L}
\end{gathered}
$$

Vol. 6, $n=4-1989$.
and

$$
\operatorname{spt} f_{₹} \mathbf{T}_{j} \subset \overline{\mathbf{B}_{\mathbf{R}}(\mathbf{0})} .
$$

Hence we may assume without loss of generality that

$$
\operatorname{spt~T}_{j} \subset \overline{\mathbf{B}_{\mathbf{R}}(0)}, \quad j \geqq 1 .
$$

The assumption $\mathbf{M}(\Gamma)<\infty$ combined with $\mathbf{M}\left(\partial \mathrm{T}_{j}-\Gamma\right) \leqq \mathrm{L}(j \geqq 1)$ yields

$$
\sup _{j \geqq 1}\left(\mathbf{M}\left(\mathrm{~T}_{j}\right)+\mathbf{M}\left(\partial \mathrm{T}_{j}\right)\right)<\infty
$$

By the compactness theorem for integral currents ([SL, 27.3]) we can select a subsequence [again denoted by $\left(\mathrm{T}_{j}\right)$ ] which converges in $\mathscr{D}_{n}\left(\mathbb{R}^{n+}\right)$ to an integral current $T \in \mathbf{I}_{n}\left(\mathbb{R}^{n+k}\right)$ which satisfies

$$
\operatorname{spt} T \subset \overline{\mathbf{B}_{R}(0)} .
$$

The lower-semicontinuity of the mass implies

$$
\mathbf{M}(\mathrm{T}) \leqq \lim _{j \rightarrow \infty} \mathbf{M}\left(\mathrm{~T}_{j}\right)
$$

and

$$
\mathbf{M}(\partial \mathbf{T}-\Gamma) \leqq \lim _{j \rightarrow \infty} \mathbf{M}\left(\partial \mathbf{T}_{j}-\Gamma\right) \leqq \mathrm{L}
$$

so that in fact

$$
\mathbf{M}(\mathrm{T})=\inf \{\mathbf{M}(\mathbf{S}) / \mathbf{S} \in \mathbf{A}(\Gamma, \mathrm{L})\} .
$$

It remains to show that $\mathbf{M}(\partial \mathbf{T}-\Gamma)=\mathbf{L}$. In order to establish this (cf. [AHW; 3.4]) we first recall that for every $x_{0} \in \operatorname{spt} \mathrm{~T} \sim \operatorname{spt} \partial \mathrm{~T}$ we have

$$
\mathbf{M}\left(\mathbf{T}\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right) \leqq c \rho^{n}, \quad \forall \rho<\operatorname{dist}\left(x_{0}, \operatorname{spt} \partial \mathbf{T}\right)\right.
$$

where the constant depends on $\mathbf{M}(\mathrm{T})$ and $x_{0}$. (This is an immediate consequence of the interior monotonicity formula for mass-minimizing currents.) We can therefore conclude that for every $\varepsilon>0$ there exists a number $\tau>0$ such that

$$
\mathbf{M}\left(\partial\left(\mathbf{T}\left\llcorner\mathbf{B}_{\tau}\left(x_{0}\right)\right)\right) \leqq \varepsilon .\right.
$$

[The slice $\partial\left(T\left\llcorner\mathbf{B}_{\tau}\left(x_{0}\right)\right)\right.$ is well-defined for $\mathscr{L}^{1}$-a. e. $\tau>0$.] Indeed if this was false the coarea-formula would immediately yield that for some $\varepsilon>0$

$$
\varepsilon \rho<\int_{0}^{\rho} \mathbf{M}\left(\partial \left(\mathbf{T}\left\llcorner\mathbf{B}_{\tau}\left(x_{0}\right)\right) d \tau \leqq \mathbf{M}\left(\mathbf{T}\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right) \leqq c \rho^{n}\right.\right.\right.
$$

holds for every $\rho<\operatorname{dist}\left(x_{0}, \operatorname{spt} \partial \mathrm{~T}\right)$.
Suppose now that $\mathbf{M}(\partial \mathrm{T}-\Gamma)<\mathrm{L}$. As above we can find a ball $\mathrm{B}_{\mathrm{r}}\left(x_{0}\right)$ about some $x_{0} \in \operatorname{spt} \mathrm{~T} \sim \operatorname{spt} \partial \mathrm{~T}$ such that

$$
\mathbf{M}\left(\partial\left(\mathbf{T}\left\llcorner\mathbf{B}_{\boldsymbol{\tau}}\left(x_{0}\right)\right)\right) \leqq \mathbf{L}-\mathbf{M}(\partial \mathbf{T}-\Gamma) .\right.
$$

The surface $\mathrm{T}^{\prime}=\mathbf{T}-\left(\mathbf{T}\left\llcorner\mathbf{B}_{\tau}\left(x_{0}\right)\right)\right.$ then satisfies

$$
\mathbf{M}\left(\mathrm{T}^{\prime}\right)<\mathbf{M}(\mathrm{T})
$$

and

$$
\mathbf{M}\left(\partial \mathrm{T}^{\prime}-\Gamma\right) \leqq \mathbf{L}
$$

thus contradicting the minimality of $T$ in $A(\Gamma, L)$.

### 1.6. Proposition

Let $\mathrm{T} \in \mathrm{I}_{n}\left(\mathbb{R}^{n+k}\right)$ be minimizing with respect to $\Gamma \in \mathrm{I}_{n-1}\left(\mathbb{R}^{n+k}\right)$ in the sense of Theorem 1.4. Then

$$
\operatorname{spt} T \subset \operatorname{conv}(\operatorname{spt} \Gamma)
$$

Proof. - We modify a well-known argument used in the case of the ordinary problem of mass-minimizing.

Since the convex hull of spt $\Gamma$ is the intersection of all balls in $\mathbb{R}^{n+k}$ which contain spt $\Gamma$ it suffices to show that spt $\Gamma \subset \overline{\mathbf{B}_{\mathbf{R}}\left(x_{0}\right)}$ implies $\operatorname{spt} \mathrm{T} \subset \overline{\mathrm{B}_{\mathrm{R}}\left(x_{0}\right)}$. By translating and scaling we may assume without loss of generality that $x_{0}=0$ and $\mathbf{R}=1$. Let $f: \mathbb{R}^{n+k} \rightarrow \overline{\mathbf{B}_{1}(0)}$ be defined by $f(x)=x$ for $|x|<1, f(x)=|x|^{-1} x$ for $|x| \geqq 1$. Since Lip $f \leqq 1$ and $f_{\sharp} \Gamma=\Gamma$ we infer as in the proof of Theorem 1.4

$$
\begin{aligned}
\mathbf{M}\left(f_{\sharp} \mathrm{T}\right) & \leqq \mathbf{M}(\mathrm{T}) \\
\mathbf{M}\left(\partial f_{\sharp} \mathrm{T}-\Gamma\right) & \leqq \mathbf{M}(\partial \mathrm{T}-\Gamma)
\end{aligned}
$$

which in view of the minimality of T implies

$$
\mathbf{M}(\mathbf{T})=\mathbf{M}\left(f_{\sharp} \mathbf{T}\right) .
$$

Using this, the fact that $f_{\#} \mathbf{T}\left\llcorner\mathrm{~B}_{1}(0)=\mathbf{T}\left\llcorner\mathbf{B}_{1}(0)\right.\right.$ and the area-formula

$$
\mathbf{M}\left(f_{\sharp} \mathbf{T}\right)=\mathbf{M}\left(f_{\sharp} \mathbf{T}\left\llcorner\mathbf{B}_{1}(0)\right)+\int_{\mathbb{R}^{n+k_{\sim}} \mathbf{B}_{1}(0)}\left|\overrightarrow{\mathbf{T}}(x) \wedge \frac{x}{|x|}\right||x|^{-n} d \mu_{\mathbf{T}}(x)\right.
$$

we obtain

$$
\int_{\mathbb{R}^{n+k_{\sim}} \sim \mathrm{B}_{1}(0)}\left(\left|\overrightarrow{\mathrm{T}}(x) \wedge \frac{x}{|x|}\right||x|^{-n}-1\right) d \mu_{\mathrm{T}}(x)=0 .
$$

Since $|\overrightarrow{\mathrm{T}}(x)|=1$ for $\mu_{\mathrm{T}}$-a. e. $x \in \mathbb{R}^{n+k}$ we conclude

$$
\mu_{\mathrm{T}}\left(\mathbb{R}^{n+k} \sim \overline{\left.\mathrm{~B}_{1}(0)\right)}=0 .\right.
$$

The following decomposition property of T and restriction property of $\Sigma$ is going to play a central role in section 2.

### 1.7. Proposition

Let $\mathrm{T} \in \mathrm{I}_{\boldsymbol{n}}(\mathrm{U})$ be a minimizer of the thread problem with respect to $\Gamma \in \mathrm{I}_{n-1}(\mathrm{U})$.
(1) Suppose the free boundary part $\Sigma=\partial \mathrm{T}-\Gamma$ is decomposed inside $\mathrm{W}_{0} \subset \mathrm{U}$ in the following way:

$$
\begin{gathered}
\Sigma=\Sigma^{\prime}+\Sigma^{\prime \prime} \\
\mathbf{M}_{\mathbf{w}_{0}}(\Sigma)=\mathbf{M}_{\mathbf{w}_{0}}\left(\Sigma^{\prime}\right)+\mathbf{M}_{\mathbf{w}_{0}}\left(\Sigma^{\prime \prime}\right)
\end{gathered}
$$

Then

$$
\mathbf{M}_{\mathbf{w}_{0}}(\mathrm{~T}) \leqq \mathbf{M}_{\mathbf{w}_{0}}(\mathbf{S})
$$

for every $\mathrm{S} \in \mathrm{I}_{n, \text { loc }}(\mathrm{U})$ satisfying $\operatorname{spt}(\mathrm{S}-\mathrm{T}) \subset \mathrm{W}_{0}$ and

$$
\mathbf{M}_{\mathbf{w}_{0}}\left(\partial S-\Gamma^{\prime}\right)=\mathbf{M}_{\mathbf{w}_{0}}\left(\Sigma^{\prime}\right)
$$

where $\Gamma^{\prime}=\partial \mathrm{T}-\Sigma^{\prime}$ is the new fixed boundary part.
(2) Suppose T can be decomposed inside $\mathrm{W}_{0} \subset \mathrm{U}$ in the following way:

$$
\begin{array}{ll}
\mathrm{T}=\mathrm{T}^{\prime}+\mathrm{T}^{\prime \prime}, & \mathbf{M}_{\mathrm{w}_{0}}(\mathrm{~T})=\mathbf{M}_{\mathbf{w}_{0}}\left(\mathrm{~T}^{\prime}\right)+\mathbf{M}_{\mathbf{w}_{0}}\left(\mathrm{~T}^{\prime \prime}\right) \\
\Gamma=\Gamma^{\prime}+\Gamma^{\prime \prime}, & \Sigma^{\prime}=\partial \mathrm{T}^{\prime}-\Gamma^{\prime}, \Sigma^{\prime \prime}=\partial \mathrm{T}^{\prime \prime}-\Gamma^{\prime \prime} \\
\Sigma=\Sigma^{\prime}+\Sigma^{\prime \prime}, & \mathbf{M}_{\mathbf{w}_{0}}(\Sigma)=\mathbf{M}_{\mathbf{w}_{0}}\left(\Sigma^{\prime}\right)+\mathbf{M}_{\mathbf{w}_{0}}\left(\Sigma^{\prime \prime}\right) .
\end{array}
$$

Then $\mathrm{T}^{\prime}$ and $\mathrm{T}^{\prime \prime}$ are minimizers of the thread problem in $\mathrm{W}_{0}$ with respect to $\Gamma^{\prime}$ and $\Gamma^{\prime \prime}$ respectively.

## Proof.

(1) We have

$$
\begin{aligned}
\mathbf{M}_{\mathbf{w}_{0}}(\partial S-\Gamma) & \leqq \mathbf{M}_{\mathbf{w}_{0}}\left(\partial S-\Gamma^{\prime}\right)+\mathbf{M}_{\mathbf{w}_{0}}\left(\Sigma^{\prime \prime}\right) \\
& =\mathbf{M}_{\mathbf{w}_{0}}\left(\Sigma^{\prime}\right)+\mathbf{M}_{\mathbf{w}_{0}}\left(\Sigma^{\prime \prime}\right) \\
& =\mathbf{M}_{\mathbf{w}_{0}}(\Sigma)=\mathbf{M}_{\mathbf{w}_{0}}(\partial T-\Gamma)
\end{aligned}
$$

From Prop. 1.3 we obtain

$$
\mathbf{M}_{\mathbf{w}_{0}}(\mathrm{~T}) \leqq \mathbf{M}_{\mathbf{w}_{0}}(\mathbf{S})
$$

(2) Let $S \in I_{n, \text { loc }}(U)$ satisfy spt $\left(S-T^{\prime}\right) \subset W_{0}$ and

$$
\mathbf{M}_{\mathbf{w}_{0}}\left(\partial \mathbf{S}-\Gamma^{\prime}\right)=\mathbf{M}_{\mathbf{w}_{0}}\left(\partial T^{\prime}-\Gamma^{\prime}\right)=\mathbf{M}_{\mathbf{w}_{0}}\left(\Sigma^{\prime}\right)
$$

Then we check as in the proof of part (1) that $S^{\prime \prime}=S+T^{\prime \prime}$ is an admissible comparison surface for $T$. This implies

$$
\mathbf{M}_{\mathbf{w}_{0}}(\mathrm{~T}) \leqq \mathbf{M}_{\mathbf{w}_{0}}\left(\mathrm{~S}^{\prime \prime}\right) \leqq \mathbf{M}_{\mathbf{w}_{0}}(\mathrm{~S})+\mathbf{M}_{\mathbf{w}_{0}}\left(\mathrm{~T}^{\prime \prime}\right)
$$

From the mass-additivity of $\mathrm{T}^{\prime}$ and $\mathrm{T}^{\prime \prime}$ in $\mathrm{W}_{0}$ we conclude

$$
\mathbf{M}_{\mathbf{W}_{0}}\left(\mathrm{~T}^{\prime}\right) \leqq \mathbf{M}_{\mathbf{W}_{0}}(\mathbf{S})
$$

## 2. THE FIRST VARIATION OF THE THREAD

The first variation of the mass of $\mathrm{S} \in \mathrm{I}_{n, \mathrm{loc}}(\mathrm{U})$ is given by (cf. [A W], [SL])

$$
\delta \mathbf{S}(\mathbf{X})=\int \operatorname{div}_{\mathbf{S}} \mathbf{X} d \mu_{\mathbf{S}}
$$

where $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{U} ; \mathbb{R}^{n+k}\right)$.
We define the support of $\delta \mathrm{S}$ in U by

$$
\operatorname{spt} \delta S=\left\{x \in U / \forall \rho>0, \exists X_{\rho} \in C_{c}^{1}\left(B_{\rho}(x) ; \mathbb{R}^{n+k}\right) \text { s. t. } \delta S\left(X_{\rho}\right) \neq 0\right\}
$$

In order to obtain some control on the first variation of the threadboundary $\Sigma$ introduced in section 1 we shall have to make use of the following crucial lemma.

### 2.1. Lemma

Let $\mathrm{T} \in \mathrm{I}_{n \text {, loc }}(\mathrm{U})$ be a minimizer of the thread problem with respect to $\Gamma \in \mathrm{I}_{n-1, \text { loc }}(\mathrm{U})$.

Then the inequality
(21) $|\delta \mathrm{T}(\mathrm{X}) \delta \Sigma(\mathrm{Y})-\delta \mathrm{T}(\mathrm{Y}) \delta \Sigma(\mathrm{X})|$

$$
\leqq|\delta \Sigma(\mathrm{Y})| \int|\mathrm{X} \wedge \vec{\Gamma}| d \mu_{\Gamma}+|\delta \Sigma(\mathrm{X})| \int|\mathrm{Y} \wedge \vec{\Gamma}| d \mu_{\Gamma}
$$

holds for every $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~V} ; \mathbb{R}^{n+k}\right)$ and $\mathrm{Y} \in \mathrm{C}_{c}^{1}\left(\mathrm{~W} ; \mathbb{R}^{n+k}\right)$ whenever
$\mathrm{V}, \mathrm{W} \subset \mathrm{U} \sim \operatorname{spt} \partial \Gamma$ are disjoint open sets.
The proof of Lemma 2.1 is based on Lagrange multiplier techniques used in [HW] and [DHL]. We give a slight generalization of Lemma 2 of [DHL] for the case where some nondifferentiable functions are involved.

### 2.2. Lemma

Let $f(s, t), g(s, t)$ be real-valued functions of $(s, t) \in\left[-s_{0}, s_{0}\right] \times\left[-t_{0}, t_{0}\right]$, $s_{0}>0, t_{0}>0$ which split in the form

$$
\begin{gathered}
f(s, t)=f_{0}+f_{1}(s)+\bar{f}_{1}(s)+f_{2}(t)+\bar{f}_{2}(t) \\
g(s, t)=g_{0}+g_{1}(s)+g_{2}(t)
\end{gathered}
$$

where $f_{0}, g_{0}$ are constants and

$$
f_{1}(0)=\bar{f}_{1}(0)=f_{2}(0)=\bar{f}_{2}(0)=g_{1}(0)=g_{2}(0)=0 .
$$

Suppose $g_{2}$ is continuous in $\left[-t_{0}, t_{0}\right]$, the derivatives $f_{1}^{\prime}(0), f_{2}^{\prime}(0), g_{1}^{\prime}(0)$, $g_{2}^{\prime}(0)$ exist and $g_{2}^{\prime}(0)=1$.

Suppose furthermore that

$$
f_{0}=f(0,0) \leqq f(s, t)
$$

for every $(s, t) \in\left[-s_{0}, s_{0}\right] \times\left[-t_{0}, t_{0}\right]$ such that $g(s, t)=g_{0}$.
Then

$$
\begin{equation*}
\left|f_{1}^{\prime}(0)-f_{2}^{\prime}(0) g_{1}^{\prime}(0)\right| \leqq \varlimsup_{s \rightarrow 0}\left|\frac{\bar{f}_{1}(s)}{s}\right|+\varlimsup_{t \rightarrow 0}\left|\frac{\bar{f}_{2}(t)}{t}\right|\left|g_{1}^{\prime}(0)\right| . \tag{2.2}
\end{equation*}
$$

Proof. - We refer the reader to Lemma 2 of [DHL]. The auxiliary function $\tau(s)$ defined there depends only on $g_{1}$ and $g_{2}$. One then immediately verifies that the difference quotient expressions corresponding to the left hand side of (2.2) can be estimated by difference quotient terms involving $\bar{f}_{1}$ and $\bar{f}_{2}$.

Proof of Lemma 2.1. - Let $\left(\varphi_{s}\right), s \in\left[-s_{0}, s_{0}\right]$ be a one-parameter family of diffeomorphisms of $U$ which leave the boundary of $\Gamma$ fixed, that is $\varphi_{0}=\mathrm{id}$ and $\operatorname{spt}\left(\varphi_{s}-\mathrm{id}\right) \subset \mathrm{V} \subset \mathrm{U} \sim \operatorname{spt} \partial \Gamma$ for $s \in\left[-s_{0}, s_{0}\right]$. Suppose furthermore that $\varphi_{s}$ satisfies

$$
\begin{equation*}
\mathbf{M}_{\mathbf{V}}\left(\varphi_{s \#} \Sigma\right)=\mathbf{M}_{\mathbf{V}}(\Sigma) . \tag{2.3}
\end{equation*}
$$

Then

$$
\mathrm{T}_{s}=\varphi_{s \sharp} \mathrm{~T}-\varphi_{\sharp}(\llbracket(0, s) \rrbracket \times \Gamma)
$$

is an admissible comparison surface for $T$ in $V$. Indeed we have $\operatorname{spt}\left(\mathrm{T}-\mathrm{T}_{s}\right) \subset \mathrm{V}$ and

$$
\begin{align*}
\partial \mathrm{T}_{s}-\Gamma & =\partial\left(\varphi_{s \sharp} \mathrm{~T}-\varphi_{\sharp}(\llbracket(0, s) \rrbracket \times \Gamma)-\Gamma\right)  \tag{2.4}\\
& =\varphi_{s \sharp} \Sigma+\varphi_{s \sharp} \Gamma-\partial \varphi_{\sharp}(\llbracket(0, s) \rrbracket \times \Gamma)-\Gamma \\
& =\varphi_{s \sharp} \Sigma+\varphi_{s \sharp} \Gamma-\varphi_{\sharp} \Gamma+\Gamma-\Gamma \\
& =\varphi_{s \sharp} \Sigma .
\end{align*}
$$

Here we used the homotopy formula for currents taking $\operatorname{spt}\left(\varphi_{s}-\mathrm{id}\right) \cap \operatorname{spt} \partial \Gamma=\varnothing$ into account.

In particular, (2.4) yields $\mathbf{M}\left(\partial \mathrm{T}_{s}-\Gamma\right)=\mathbf{M}(\partial \mathbf{T}-\Gamma)$ which by the minimality of T implies

$$
\begin{align*}
\mathbf{M}_{\mathbf{V}}(\mathrm{T}) & \leqq \mathbf{M}_{\mathbf{V}}\left(\mathbf{T}_{s}\right)  \tag{2.5}\\
& \leqq \mathbf{M}_{\mathbf{V}}\left(\varphi_{s \sharp} \mathbf{T}\right)+\mathbf{M}_{\mathbf{V}}\left(\varphi_{\sharp}(\llbracket(0, s) \rrbracket \times \Gamma)\right) .
\end{align*}
$$

Suppose $\varphi_{s}(x)=x+s X$ where $X \in C_{c}^{1}\left(\mathrm{~V} ; \mathbb{R}^{n+k}\right)$. Then we compute as in ([BJ], Lemma 3.1)

$$
\begin{aligned}
& \mathbf{M}\left(\varphi_{\xi}([(0, s) \rrbracket \times \Gamma))\right. \\
&=\int_{0}^{s} \int\left|\dot{\varphi}_{\tau}(x) \wedge\left(d_{x} \varphi_{\tau}\right)_{\ddagger}(\vec{\Gamma}(x))\right| d \mu_{\Gamma}(x) d \tau \\
&=\int_{0}^{s} \int\left|\mathrm{X} \wedge \vec{\Gamma}(x)+\mathrm{X} \wedge \tau^{n-1}(\mathrm{DX}(x))_{\xi}(\vec{\Gamma}(x))\right| d \mu_{\Gamma}(x) d \tau
\end{aligned}
$$

which implies

$$
\begin{equation*}
\varlimsup_{s \rightarrow 0}\left|\frac{\mathbf{M}\left(\varphi_{\ddagger}(\llbracket(0, s) \rrbracket \times \Gamma)\right)}{s}\right|=\int|\mathbf{X} \wedge \vec{\Gamma}| d \mu_{\Gamma} . \tag{2.6}
\end{equation*}
$$

Let now $\mathrm{V}, \mathrm{W}$ be two disjoint open sets which are compactly contained in $U \sim \operatorname{spt} \partial \Gamma$ and choose variation vectorfields $X \in C_{c}^{1}\left(V ; \mathbb{R}^{n+k}\right)$ and $\mathrm{Y} \in \mathrm{C}_{c}^{1}\left(\mathrm{~W} ; \mathbb{R}^{n+k}\right)$. Let $\boldsymbol{\Omega} \subset \mathrm{U}$ be an open set such that $\mathrm{V} \cup \mathrm{W} \subset \Omega$. For one-parameter deformations

$$
\varphi_{s}(x)=x+s \mathrm{X}(x), \quad \psi_{t}(x)=x+t \mathrm{Y}(x)
$$

$(s, t) \in\left[-s_{0}, s_{0}\right] \times\left[-t_{0}, t_{0}\right]$, we define

$$
\begin{gathered}
f_{0}=\mathbf{M}_{\Omega}(\mathrm{T}), \quad g_{0}=\mathbf{M}_{\Omega}(\Sigma) \\
f_{1}(s)=\mathbf{M}_{\mathrm{V}}\left(\varphi_{s \sharp} \mathrm{~T}\right)-\mathbf{M}_{\mathrm{V}}(\mathrm{~T}) \\
\overline{f_{1}}(s)=\mathbf{M}_{\mathbf{V}}\left(\varphi_{\sharp}(\llbracket(0, s) \rrbracket \times \Gamma)\right) \\
f_{2}(t)=\mathbf{M}_{\mathbf{w}}\left(\psi_{t ¥} \mathrm{~T}\right)-\mathbf{M}_{\mathbf{W}}(\mathrm{T}) \\
\overline{f_{2}}(t)=\mathbf{M}_{\mathbf{W}}\left(\psi_{\sharp}(\llbracket(0, t) \rrbracket \times \Gamma)\right) \\
g_{1}(s)=\mathbf{M}_{\mathbf{V}}\left(\varphi_{s \sharp} \Sigma\right)-\mathbf{M}_{\mathbf{V}}(\Sigma) \\
g_{2}(t)=\mathbf{M}_{\mathbf{W}}\left(\psi_{t \#} \Sigma\right)-\mathbf{M}_{\mathbf{w}}(\Sigma)
\end{gathered}
$$

and $f(s, t), g(s, t)$ as in Lemma 2.2. Let

$$
\mathrm{T}_{s, t}=\varphi_{s \sharp} \mathrm{~T}-\varphi_{\sharp}(\llbracket(0, s) \rrbracket \times \Gamma)+\psi_{t \sharp} \mathrm{~T}-\psi_{\sharp}(\llbracket(0, t) \rrbracket \times \Gamma) .
$$

From the definition of $\varphi_{s}$ and $\psi_{t}$ we infer

$$
\operatorname{spt}\left(\mathrm{T}_{s, t}-\mathrm{T}\right) \subset \Omega
$$

Furthermore we derive from (2.4)

$$
\mathbf{M}_{\Omega}\left(\partial \mathrm{T}_{s, t}-\Gamma\right)=\mathbf{M}_{\mathbf{v}}\left(\varphi_{s \sharp} \Sigma\right)+\mathbf{M}_{\mathbf{w}}\left(\psi_{t \sharp} \Sigma\right)+\mathbf{M}_{\Omega \sim(\mathbf{v} \cup \mathbf{w})}(\Sigma)
$$

For those $(s, t) \in\left[-s_{0}, s_{0}\right] \times\left[-t_{0}, t_{0}\right]$ which satisfy $g(s, t)=g_{0}$ we have

$$
\mathbf{M}_{\mathbf{V}}\left(\varphi_{s \sharp} \Sigma\right)+\mathbf{M}_{\mathbf{w}}\left(\psi_{t \sharp} \Sigma\right)=\mathbf{M}_{\mathbf{V}}(\Sigma)+\mathbf{M}_{\mathbf{w}}(\Sigma) .
$$

This implies [for such $(s, t)$ ]

$$
\mathbf{M}_{\Omega}\left(\partial \mathrm{T}_{s, t}-\Gamma\right)=\mathbf{M}_{\Omega}(\partial \mathrm{T}-\Gamma)
$$

which establishes $\mathrm{T}_{s, t}$ as an admissible comparison surface. As in (2.5) we conclude

$$
\begin{aligned}
\mathbf{M}_{\Omega}(\mathrm{T}) \leqq & \mathbf{M}_{\Omega}\left(\mathrm{T}_{s, t}\right) \\
& \leqq \mathbf{M}_{\mathbf{V}}\left(\varphi_{s \sharp} \mathrm{~T}\right)+\mathbf{M}_{\mathbf{W}}\left(\psi_{t \sharp} \mathbf{T}\right)+\mathbf{M}_{\mathbf{V}}\left(\varphi_{\sharp}(\llbracket(0, s) \rrbracket \times \Gamma)\right) \\
& +\mathbf{M}_{\mathbf{W}}\left(\psi_{\#}(\llbracket(0, t) \rrbracket \times \Gamma)\right)+\mathbf{M}_{\Omega \sim(\mathrm{V} \cup \mathbf{w})}(\mathrm{T}) .
\end{aligned}
$$

In view of the definition of $f_{1}, \bar{f}_{1}, f_{2}$ and $\bar{f}_{2}$ this implies for $(s, t)$ satisfying $g(s, t)=g_{0}$

$$
0 \leqq f_{1}(s)+\bar{f}_{1}(s)+f_{2}(t)+\bar{f}_{2}(t)
$$

which is equivalent to

$$
f(0,0) \leqq f(s, t)
$$

for every $(s, t)$ s.t. $g(s, t)=g_{0}$. Moreover

$$
f_{1}(0)=\bar{f}_{1}(0)=f_{2}(0)=\bar{f}_{2}(0)=g_{1}(0)=g_{2}(0)=0
$$

and all the differentiability and continuity requirements of Lemma 2.2 are satisfied.

In case $\delta \Sigma(X)=0$ for all $X \in C_{c}^{1}\left(U \sim \operatorname{spt} \partial \Gamma ; \mathbb{R}^{n+k}\right)$ the statement of Lemma 2.1 holds trivially. Hence we may assume $\mathrm{Y} \in \mathrm{C}_{c}^{1}\left(\mathrm{~W} ; \mathbb{R}^{n+k}\right)$ satisfies $\delta \Sigma(\mathrm{Y}) \neq 0$ and set $\mathrm{Y}^{\prime}=\delta \Sigma(\mathrm{Y})^{-1} \mathrm{Y}$. This gives $\delta \Sigma\left(\mathrm{Y}^{\prime}\right)=1$ which by the definition of $g_{2}$ represents the condition $g_{2}^{\prime}(0)=1$.

We can now apply Lemma 2.2, the definition of first variation to $f_{1}, f_{2}, \mathrm{~g}_{1}, g_{2}$ and (2.6) to $\bar{f}_{1}$ and $\bar{f}_{2}$ to arrive at

$$
\left|\delta \mathrm{T}(\mathrm{X})-\delta \mathrm{T}\left(\mathrm{Y}^{\prime}\right) \delta \Sigma(\mathrm{X})\right| \leqq \int|\mathrm{X} \wedge \vec{\Gamma}| d \mu_{\Gamma}+|\delta \Sigma(\mathrm{X})| \int\left|\mathrm{Y}^{\prime} \wedge \vec{\Gamma}\right| d \mu_{\Gamma}
$$

for $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~V} ; \mathbb{R}^{n+k}\right)$ and $\mathrm{Y}^{\prime}=\delta \Sigma(\mathrm{Y})^{-1} \mathrm{Y} \in \mathrm{C}_{c}^{1}\left(\mathrm{~W} ; \mathbb{R}^{n+k}\right)$ which completes the proof of (2.1).

We now turn to establishing the main result of this paper.

### 2.3. Theorem

Let $\mathrm{T} \in \mathrm{I}_{n, \text { loc }}(\mathrm{U})$ be a minimizer of the thread problem with respect to $\Gamma \in \mathrm{I}_{n-1, \mathrm{loc}}(\mathrm{U})$.

Suppose

$$
\begin{equation*}
\operatorname{spt} \delta \Sigma \sim \operatorname{spt} \partial \Gamma \neq \varnothing \tag{A1}
\end{equation*}
$$

(A2) There exists a point $x_{0} \in \operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma$, a radius $\rho<\operatorname{dist}\left(x_{0}, \operatorname{spt} \hat{\sigma}\right)$ and a local decomposition

$$
T L B_{\rho}\left(x_{0}\right)=T_{0}\left\llcorner B_{\rho}\left(x_{0}\right)+\left(T-T_{0}\right)\left\llcorner B_{\rho}\left(x_{0}\right)\right.\right.
$$

satisfying $\mathrm{T}_{0} \in \mathrm{I}_{\text {, loc }}(\mathrm{U})$,
(1) $\left\{\begin{array}{l}\mathbf{M}\left(T\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)=\mathbf{M}\left(T_{0}\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)+\mathbf{M}\left(\left(T-T_{0}\right)\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)\right)\right.\right. \\ \mathbf{M}\left(\Sigma\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)=\mathbf{M}\left(\Sigma_{0}\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)+\mathbf{M}\left(\left(\Sigma-\Sigma_{0}\right)\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)\right.\right.\right.\end{array}\right.$
for $\Sigma_{0}=\partial \mathrm{T}_{0}$ and

$$
\begin{equation*}
x_{0} \in \operatorname{spt} \delta \mathrm{~T}_{0} \tag{2}
\end{equation*}
$$

Then we can find a number $\lambda_{\Sigma} \in(0, \infty)$ such that

$$
\begin{equation*}
\left|\delta \mathrm{T}(\mathrm{X})+\lambda_{\Sigma} \delta \Sigma(\mathrm{X})\right| \leqq \int|\mathrm{X} \wedge \vec{\Gamma}| d \mu_{\Gamma} \tag{2.7}
\end{equation*}
$$

holds for every $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{U} \sim \operatorname{spt} \partial \Gamma ; \mathbb{R}^{n+k}\right)$, where $\lambda_{\mathrm{\Sigma}}$ is given by

$$
\begin{equation*}
\delta \mathrm{T}_{0}(\mathrm{X})+\lambda_{\Sigma} \delta \Sigma_{0}(\mathrm{X})=0 \tag{2.8}
\end{equation*}
$$

for every $\mathbf{X} \in \mathbf{C}_{c}^{1}\left(\mathbf{B}_{\rho}\left(x_{0}\right) ; \mathbb{R}^{n+k}\right)$.
Moreover (2.8), at any point of $\operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma$ satisfying (A2) and for any possible decomposition at such a point, is valid with the same $\lambda_{\Sigma}>0$.

### 2.4. Remark

(1) If (A1) is not satisfied $\Sigma$ is a stationary thread away from $\partial \Sigma=-\partial \Gamma$. For the structure of such boundaries we refer to Corollary 2.10 and Theorem 3.1.
(2) Although in the codimension one case, i.e. $\mathrm{U} \subset \mathbb{R}^{n+1}$ condition (A2) can be verified under reasonably weak hypotheses it nevertheless appears to be a rather artificial assumption which one would hope, could be removed altogether.

In fact if $U \subset \mathbb{R}^{n+1}$ it suffices to assume the existence of at least one regular point of $\operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma$ in the sense of Proposition 2.7 (1).

Proof of Theorem 2.3. - We first prove (2.7) assuming

$$
\begin{equation*}
\text { spt } \delta \mathrm{T} \sim \operatorname{spt} \Gamma \neq \varnothing \tag{B2}
\end{equation*}
$$

From Remark 1.2 (2) and ([BJ], Lemma 3.1) we infer

$$
\begin{equation*}
|\delta \mathrm{T}(\mathrm{X})| \leqq \int|\mathrm{X} \wedge \overline{\partial \mathrm{~T}}| d \mu_{\partial \mathrm{T}} \tag{2.9}
\end{equation*}
$$

for every $X \in C_{c}^{1}\left(U ; \mathbb{R}^{n+k}\right)$. In particular, the representation formula for $\delta \mathrm{T}$ (cf. [SL], Chapt. 8])

$$
\begin{equation*}
\delta T(X)=\int v_{\partial \mathrm{T}} \cdot \mathrm{X} d \mu_{\partial \mathrm{T}} \tag{2.10}
\end{equation*}
$$

Vol. 6, $n^{c}$ 4-1989.
holds for $X \in C_{c}^{1}\left(U ; \mathbb{R}^{n+k}\right)$, where $v_{\partial T}$ is a $\mu_{\partial T}$-measurable vectorfield in $U$ satisfying $\left|v_{\partial T}\right| \leqq 1 \mu_{\partial T}-$ a. e. Assumption (B2) implies that

$$
\begin{equation*}
\mu_{\partial \mathrm{T}}\left(\left\{x \in \operatorname{spt} \Sigma \sim \operatorname{spt} \Gamma / v_{\partial T}(x) \neq 0\right\}\right)>0 . \tag{2.11}
\end{equation*}
$$

Hence we may select three points $x_{1}, x_{2}, x_{3} \in \operatorname{spt} \delta T \sim \operatorname{spt} \Gamma$, radii $\rho_{i}<\operatorname{dist}\left(x_{i}, \operatorname{spt} \Gamma\right)$ s. t. $\quad \mathbf{B}_{\rho_{i}}\left(x_{i}\right) \cap \mathrm{B}_{\rho_{j}}\left(x_{j}\right)=\varnothing$ for $i \neq j(i, j=1,2,3)$ and variation vectorfields $\mathrm{X}_{i} \in \mathrm{C}_{c}^{1}\left(\mathrm{~B}_{\mathrm{p}_{i}}\left(x_{i}\right) ; \mathbb{R}^{n+k}\right)$ which satisfy

$$
\begin{equation*}
\delta \mathrm{T}\left(\mathrm{X}_{i}\right) \neq 0, \quad i=1,2,3 . \tag{2.12}
\end{equation*}
$$

From (A1) we obtain the existence of a point $x_{0} \in \operatorname{spt} \delta \Sigma \sim \operatorname{spt} \partial \Gamma$, a radius $\rho_{0}<\operatorname{dist}\left(y_{0}, \operatorname{spt} \partial \Gamma\right)$ and a vectorfield $Y_{0} \in C_{c}^{1}\left(B_{\rho_{0}}\left(y_{0}\right) ; \mathbb{R}^{n+k}\right)$ such that

$$
\begin{equation*}
\delta \Sigma\left(Y_{0}\right) \neq 0 \tag{2.13}
\end{equation*}
$$

We may assume $\mathrm{B}_{\mathrm{\rho}_{0}}\left(y_{0}\right) \cap \mathrm{B}_{\boldsymbol{\rho}_{i}}\left(x_{i}\right)=\varnothing$ for $i=1,2$, 3. Otherwise, by virtue of (2.11), we can choose different $x_{i} \in \operatorname{spt} \delta \mathrm{~T} \sim \operatorname{spt} \Gamma$ and $\rho_{i}>0$.

Applying now (2.1) to the pairs $X_{i}, \mathrm{Y}_{0}$ for $i=1,2,3$ we obtain

$$
\left|\delta \mathrm{T}\left(\mathrm{X}_{i}\right) \delta \Sigma\left(\mathrm{Y}_{0}\right)-\delta \mathrm{T}\left(\mathrm{Y}_{0}\right) \delta \Sigma\left(\mathrm{X}_{i}\right)\right| \leqq\left|\delta \Sigma\left(\mathrm{X}_{i}\right)\right| \int\left|\mathrm{Y}_{0} \wedge \vec{\Gamma}\right| d \mu_{\mathrm{r}}
$$

Hence from (2.12) and (2.13) we deduce

$$
\begin{equation*}
\delta \Sigma\left(\mathrm{X}_{i}\right) \neq 0, \quad i=1,2,3 . \tag{2.14}
\end{equation*}
$$

If we apply (2.1) to the pairs $X_{i}, X_{3}$ for $i=1,2$ and take (2.14) into account we derive

$$
\delta \mathrm{T}\left(\mathrm{X}_{3}\right)-\frac{\delta \mathrm{T}\left(\mathrm{X}_{1}\right)}{\delta \Sigma\left(\mathrm{X}_{1}\right)} \delta \Sigma\left(\mathrm{X}_{3}\right)=\delta \mathrm{T}\left(\mathrm{X}_{3}\right)-\frac{\delta \mathrm{T}\left(\mathrm{X}_{2}\right)}{\delta \Sigma\left(\mathrm{X}_{2}\right)} \delta \Sigma\left(\mathrm{X}_{3}\right)
$$

which implies, in view of (2.14) again,

$$
\frac{\delta \mathrm{T}\left(\mathrm{X}_{1}\right)}{\delta \Sigma\left(\mathrm{X}_{1}\right)}=\frac{\delta \mathrm{T}\left(\mathrm{X}_{2}\right)}{\delta \Sigma\left(\mathrm{X}_{2}\right)}
$$

At this stage we define

$$
\begin{equation*}
\lambda_{\Sigma}=-\frac{\delta T\left(X_{1}\right)}{\delta \Sigma\left(\mathrm{X}_{1}\right)} \neq 0 . \tag{2.15}
\end{equation*}
$$

An arbitrary vectorfield $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{U} \sim \operatorname{spt} \partial \Gamma ; \mathbb{R}^{n+k}\right)$ we decompose as follows: $\mathrm{X}=\mathrm{X}^{(1)}+\mathrm{X}^{(2)}$, where $\mathrm{X}^{(i)}=\mathrm{X} \eta^{(i)}(i=1,2)$ and $\eta^{(i)} \in \mathrm{C}^{\infty}(\mathrm{U})$ satisfies spt $\eta^{(i)} \cap \mathrm{B}_{\mathrm{p}_{i}}\left(x_{i}\right)=\varnothing, 0 \leqq \eta^{(i)} \leqq 1$ and $\eta^{(1)}+\eta^{(2)}=1$.

Using (2.1) again, this time with $\mathrm{X}_{i}, \mathrm{X}^{(i)}(i=1,2)$, we obtain

$$
\left|\delta \mathbf{T}\left(\mathbf{X}^{(i)}\right)+\lambda_{\Sigma} \delta \Sigma\left(\mathbf{X}^{(i)}\right)\right| \leqq \int\left|\mathbf{X}^{(i)} \wedge \vec{\Gamma}\right| d \mu_{\Gamma}
$$

for $i=1,2$ which in turn establishes (2.7). Note that

$$
\begin{equation*}
\delta \mathrm{T}(\mathrm{X})+\lambda_{\Sigma} \delta \Sigma(\mathrm{X})=0 \tag{2.16}
\end{equation*}
$$

holds for all $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{U} \sim \operatorname{spt} \Gamma ; \mathbb{R}^{n+k}\right)$.
Before we prove the result under the general assumption we want to show that (2.16) implies $\lambda_{\Sigma}>0$.
We already know $\lambda_{\Sigma} \neq 0$ [see (2.15)]. Suppose $\lambda_{\Sigma}<0$. Select a variation $\mathrm{Y} \in \mathrm{C}_{c}^{1}\left(\mathrm{U} \sim \operatorname{spt} \Gamma ; \mathbb{R}^{n+k}\right)$ satisfying $\delta \Sigma(\mathrm{Y})<0$. (2.16) then yields $\delta \mathrm{T}(\mathrm{Y})<0$. If we let $\left(\psi_{t}\right)$ denote the one-parameter family of deformations generated by Y this implies that for some small $t>0$ we have

$$
\mathbf{M}_{\mathrm{spt} Y}\left(\psi_{t \sharp} T\right)<\mathbf{M}_{\mathrm{spt}}(\mathbf{T})
$$

and

$$
\mathbf{M}_{\mathrm{spt} \mathrm{Y}}\left(\psi_{t \#} \Sigma\right)<\mathbf{M}_{\mathrm{spt} \mathrm{Y}}(\Sigma)
$$

which in view of Proposition 1.3 contradicts the minimality of T.
Suppose now that condition (A2) holds instead of (B2).
By virtue of Proposition (1.7) (2) and (A2) (1) $\mathrm{T}_{0}$ minimizes the thread problem in $\mathrm{B}_{\mathrm{\rho}}\left(x_{0}\right)$ with respect to $\Gamma=0$. Hence in view of (A2) (2) [which for $\mathrm{T}_{0}$ reduces to condition (B2)] and (2.11) we may select two points $x_{1}, x_{2} \in \operatorname{spt} \delta \mathrm{~T}_{0} \cap \operatorname{spt} \Sigma_{0}$ and radii $\rho_{1}, \rho_{2}$ such that $\mathbf{B}_{\rho_{1}}\left(x_{1}\right) \cap \mathbf{B}_{\rho_{2}}\left(x_{2}\right)=\varnothing$ and $B_{\rho_{1}}\left(x_{1}\right) \cup B_{\rho_{2}}\left(x_{2}\right) \subset B_{\rho}\left(x_{0}\right)$.
For $i=1,2$ we define

$$
\begin{gather*}
\mathrm{T}_{i}=\mathrm{T}-\left(\mathrm{T}-\mathrm{T}_{0}\right)\left\llcorner\mathrm{B}_{\mathrm{\rho}_{i}}\left(x_{i}\right)\right. \\
\Gamma_{i}=\Gamma-\Gamma\left\llcorner\mathrm{B}_{\mathrm{\rho}_{i}}\left(x_{i}\right)\right.  \tag{2.17}\\
\Sigma_{i}=\partial \mathrm{T}_{i}-\Gamma_{i} \\
\mathrm{U}_{i}=\left(\mathrm{U} \sim \overline{\mathrm{~B}}_{\mathrm{\rho}_{i}}\left(x_{i}\right)\right) \cup \mathrm{B}_{\mathrm{\rho}_{i} / 2}\left(x_{i}\right)
\end{gather*}
$$

such that

$$
\begin{gather*}
\mathrm{T}_{i}=\mathrm{T}_{0} \quad \text { in } \mathrm{B}_{\mathrm{\rho}_{i}}\left(x_{i}\right), \\
\mathrm{T}_{i}=\mathrm{T} \quad \text { in } \mathrm{U} \sim \overline{\mathrm{~B}_{\rho_{i}}\left(x_{i}\right)}  \tag{2.18}\\
\Sigma_{i}=\Sigma_{0} \quad \text { in } \mathrm{B}_{\mathrm{\rho}_{i}\left(x_{i}\right)}, \\
\Sigma_{i}=\Sigma \quad \text { in } \mathrm{U} \sim{\overline{\mathrm{~B}} \mathrm{\rho}_{i}}\left(x_{i}\right) .
\end{gather*}
$$

We infer from (A2) (1) that for $i=1,2$ the pair $\mathrm{T}_{i}, \mathrm{~T}-\mathrm{T}_{i}$ (replacing $\mathrm{T}^{\prime}, \mathrm{T}^{\prime \prime}$ ) satisfies the conditions of Proposition 1.7 (2) for every open $\mathrm{W} \subset \mathrm{U}_{i}$. Hence $\mathrm{T}_{i}$ is a minimizer of the thread problem in $\mathrm{U}_{i}$ with respect to $\Gamma_{i}$. Due to the choice of $x_{1}$ and $x_{2}$ we have for $i=1,2$ in $U_{i}$

$$
\begin{equation*}
\operatorname{spt} \delta \mathrm{T}_{i} \sim \operatorname{spt} \Gamma_{i} \neq \varnothing \tag{2.19}
\end{equation*}
$$

Moreover, in view of (A1) and (2.11) applied to $\mathrm{T}_{0}$ we may assume $x_{i}$ and $\rho_{i}$ to be chosen such that

$$
\begin{equation*}
\operatorname{spt} \delta \Sigma_{i} \sim \operatorname{spt} \partial \Gamma_{i} \neq \varnothing \tag{2.20}
\end{equation*}
$$

for $i=1,2$.
Therefore $\mathrm{T}_{i}$ satisfies the conditions (A1) and (B2). From (2.7), (2.16) and (2.18) we derive

$$
\begin{equation*}
\left|\delta \mathrm{T}_{i}(\mathrm{X})+\lambda_{\Sigma}^{i} \delta \Sigma_{i}(\mathrm{X})\right| \leqq \int\left|\mathrm{X} \wedge \vec{\Gamma}_{i}\right| d \mu_{\Gamma_{i}} \tag{2.21}
\end{equation*}
$$

for every $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{U}_{i} \sim \operatorname{spt} \partial \Gamma_{i} ; \mathbb{R}^{n+k}\right)$ where $\lambda_{\Sigma}^{i}>0$ is defined by

$$
\begin{equation*}
\delta \mathrm{T}_{0}(\mathrm{X})+\lambda_{\Sigma}^{i} \delta \Sigma_{0}(\mathrm{X})=0 \tag{2.22}
\end{equation*}
$$

for every $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~B}_{\mathrm{\rho}_{i} / 2}\left(x_{i}\right) ; \mathbb{R}^{n+k}\right)(i=1,2)$.
The identity (2.22) and $x_{i} \in \operatorname{spt} \delta \mathrm{~T}_{0} \cap \operatorname{spt} \Sigma_{0}$ for $i=1,2$ imply that $x_{i} \in \operatorname{spt} \delta \Sigma_{0}$. Therefore $\mathrm{T}_{0}$, which minimizes the thread problem in $\mathrm{B}_{\mathrm{\rho}}\left(x_{0}\right)$ with respect to $\Gamma=0$, also satisfies (A1) and (B2) there, such that (2.7) is applicable to $\mathrm{T}_{0}$. This establishes (2.8) for every $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~B}_{\mathrm{\rho}}\left(x_{0}\right) ; \mathbb{R}^{n+\kappa}\right)$. Hence $\lambda_{\Sigma}^{1}=\lambda_{\Sigma}^{2}$.

From (2.21) we now obtain in particular

$$
\begin{equation*}
\left|\delta \mathrm{T}(\mathrm{X})+\lambda_{\Sigma} \delta \Sigma(\mathrm{X})\right| \leqq \int|\mathrm{X} \wedge \vec{\Gamma}| d \mu_{\Gamma} \tag{2.23}
\end{equation*}
$$

for every $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{U} \sim \operatorname{spt} \partial \Gamma ; \mathbb{R}^{n+k}\right)$ satisfying $\operatorname{spt} \mathrm{X} \cap \mathrm{B}_{\mathrm{\rho}_{i}}\left(x_{i}\right)=\varnothing$, where $i=1,2$.

If $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{U} \sim \operatorname{spt} \partial \Gamma ; \mathbb{R}^{n+k}\right)$ is arbitrary, we decompose it as in the first part of the proof and apply (2.23) to arrive at inequality (2.7).

It remains to show that $\lambda_{\Sigma}$ is independent of $x_{0}$ and $T_{0}$.
Suppose that we have two decompositions at $x_{0}$, that is (A2) holds for $\mathrm{T}_{0}$ replaced by $\mathrm{T}_{0}^{1}$ and $\mathrm{T}_{0}^{2}$ respectively. From (2.8) we obtain

$$
\begin{equation*}
\delta \mathrm{T}_{0}^{i}(\mathrm{X})+\lambda_{\Sigma}^{i} \delta \Sigma_{0}^{i}(\mathrm{X})=0 \tag{2.24}
\end{equation*}
$$

for some $\lambda_{\Sigma}^{i}>0 \quad(i=1,2)$ and for every $X \in C_{c}^{1}\left(B_{\rho}\left(x_{0}\right) ; \mathbb{R}^{n+k}\right)$. Pick $y_{i} \in \operatorname{spt} \delta \mathrm{~T}_{0}^{i}$ and radii $\sigma_{i}(i=1,2)$ such that $\mathbf{B}_{\sigma_{1}}\left(y_{1}\right) \cap \mathbf{B}_{\sigma_{2}}\left(y_{2}\right)=\varnothing$ and $\mathbf{B}_{\sigma_{1}}\left(y_{1}\right) \cup \mathbf{B}_{\boldsymbol{\sigma}_{2}}\left(y_{2}\right) \subset \mathbf{B}_{\rho}\left(x_{0}\right)$. Then (2.24) implies $y_{i} \in \operatorname{spt} \delta \Sigma_{0}^{i}$.

Define

$$
\mathrm{T}_{1,2}=\mathrm{T}_{0}^{1}\left\llcorner\mathrm{~B}_{\sigma_{1}}\left(y_{1}\right)+\mathrm{T}_{0}^{2}\left\llcorner\mathrm{~B}_{\sigma_{2}}\left(y_{2}\right)\right.\right.
$$

In view of (A2) (1), for $T_{0}^{1}$ and $T_{0}^{2}$ respectively, $T_{1,2}$ and $T-T_{1,2}$ satisfy the conditions of Proposition 1.7 (2) in $U_{1,2}=B_{\sigma_{1} / 2}\left(y_{1}\right) \cup B_{\sigma_{2} / 2}\left(y_{2}\right)$. Thus $\mathrm{T}_{1,2}$ is a minimizer of the thread problem in $\mathrm{U}_{1,2}$ with respect to $\Gamma=0$.

Moreover since $y_{i} \in \mathrm{spt} \delta \mathrm{T}_{1,2} \cap \mathrm{spt} \delta \Sigma_{1,2}(i=1,2)$, where $\Sigma_{1,2}=\partial \mathrm{T}_{1,2}$, (A1) and (A2) are satisfied, which enables us to apply (2.7). Thus

$$
\begin{equation*}
\delta \mathrm{T}_{1,2}(\mathrm{X})+\lambda_{\Sigma}^{1,2} \delta \Sigma_{1,2}(\mathrm{X})=0 \tag{2.25}
\end{equation*}
$$

for every $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{U}_{1,2} ; \mathbb{R}^{n+k}\right)$ where $\lambda_{\Sigma}^{1,2}>0$.
By the definition of $T_{1,2}$ this reduces to

$$
\begin{equation*}
\delta \mathrm{T}_{0}^{i}(\mathrm{X})+\lambda_{\Sigma}^{1,2} \delta \Sigma_{0}^{i}(\mathrm{X})=0 \tag{2.26}
\end{equation*}
$$

for $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~B}_{\sigma_{i / 2}}\left(y_{i}\right) ; \mathbb{R}^{n+k}\right), i=1,2$.
The fact that $y_{i} \in \operatorname{spt} \delta \Sigma_{0}^{i}$ implies the existence of vectorfields $\mathrm{Y}_{i} \in \mathrm{C}_{c}^{1}\left(\mathrm{~B}_{\sigma_{i / 2}}\left(y_{i}\right) ; \mathbb{R}^{n+k}\right)$ which satisfy $\delta \Sigma_{0}^{i}\left(\mathrm{Y}_{i}\right) \neq 0$. Applying now (2.24) and (2.26) to $Y_{i}(i=1,2)$ yields $\lambda_{\Sigma}^{1,2}=\lambda_{\Sigma}^{1}=\lambda_{\Sigma}^{2}$.

For decomposition components at distinct points of $\operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma$ the same argument obviously works.

This completes the proof of the theorem.

### 2.5. Corollary

Let $\mathrm{T} \in \mathrm{I}_{n, \text { loc }}(\mathrm{U})$ satisfy the assumptions of Theorem 2.3. Suppose that $\Gamma$ additionally satisfies
(A3) (1) For every $x_{0} \in \operatorname{spt} \Gamma \sim \operatorname{spt} \partial \Gamma$ there exists $a$ radius $\rho\left(x_{0}\right)<\operatorname{dist}\left(x_{0}, \operatorname{spt} \partial \Gamma\right)$ and a constant $c\left(x_{0}\right)$ such that for every $x \in \mathrm{~B}_{\rho\left(x_{0}\right)}\left(x_{0}\right)$ and $\rho<\rho\left(x_{0}\right)-\left|x-x_{0}\right|$

$$
\mu_{\Gamma}\left(\mathrm{B}_{\rho}\left(x_{0}\right)\right) \leqq c\left(x_{0}\right) \rho^{n-2+\beta}
$$

for some $\beta>0$.
(2) For every $\mathrm{W} \propto \mathrm{U} \sim \mathrm{spt} \partial \Gamma$ there is a constant $c(\mathrm{~W})$ such that

$$
\mid \theta_{\Gamma}\left\llcorner\mathbf{W} \mid \leqq c(\mathbf{W}), \quad \mu_{\Gamma}-\text { a. e. } \quad \text { in } \mathbf{W}\right.
$$

where $\theta_{\Gamma}$ is the multiplicity function of $\Gamma$.
Then $\Sigma$ has bounded generalized mean curvature $\mathrm{H}_{\Sigma}$, in fact

$$
\begin{equation*}
\int \operatorname{div}_{\Sigma} \mathbf{X} d \mu_{\Sigma}=-\int \mathbf{H}_{\Sigma} \cdot \mathbf{X} d \mu_{\Sigma} \tag{2.27}
\end{equation*}
$$

for every $X \in C_{c}^{1}\left(U \sim \operatorname{spt} \partial \Gamma ; \mathbb{R}^{n+k}\right)$, where $H_{\Sigma}$ satisfies

$$
\begin{equation*}
\left\lvert\, \mathrm{H}_{\Sigma}\left\llcorner\mathrm{W} \left\lvert\, \leqq \frac{c(\mathrm{~W})}{\lambda_{\Sigma}}\right., \quad \mu_{\Sigma}-\mathrm{a} . \mathrm{e} . \quad \text { in } \mathrm{W}\right.\right. \tag{2.28}
\end{equation*}
$$

for every $\mathrm{W} \subset \mathrm{U} \sim \operatorname{spt} \partial \Gamma$, where $c(\mathrm{~W})$ depends on W only.
Proof. - We combine (2.7) and (2.9) to obtain

$$
|\delta \Sigma(\mathrm{X})| \leqq \frac{1}{\lambda_{\Sigma}}\left(\int|\mathrm{X} \wedge \vec{\Gamma}| d \mu_{\Gamma}+\int|\mathrm{X} \wedge \overrightarrow{\partial \mathrm{~T}}| d \mu_{\partial \mathrm{T}}\right)
$$

for $X \in C_{c}^{1}\left(U \sim \operatorname{spt} \partial \Gamma ; \mathbb{R}^{n+k}\right)$, which in view of the fact that $\mu_{\partial \mathrm{T}} \leqq \mu_{\Gamma}+\mu_{\Sigma}$ yields

$$
|\delta \Sigma(\mathrm{X})| \leqq \frac{1}{\lambda_{\Sigma}} \int|\mathrm{X}| d \mu_{\Sigma}+\frac{2}{\lambda_{\Sigma}} \int|\mathrm{X}| d \mu_{\Gamma}
$$

for every $X \in C_{c}^{1}\left(\mathrm{U} \sim \operatorname{spt} \partial \Gamma ; \mathbb{R}^{n+k}\right)$.
We now proceed as in ([SL] 17.6) to obtain for every $x \in B_{\rho\left(x_{0}\right)}\left(x_{0}\right)$ and $\mathscr{L}^{1}$-a. e. $\rho \leqq \rho\left(x_{0}\right)-\left|x-x_{0}\right|$

$$
\frac{d}{d \rho}\left(\rho^{1-n} \mu_{\Sigma}\left(B_{\rho}\left(x_{0}\right)\right)\right) \geqq-\frac{1}{\lambda_{\Sigma}} \rho^{1-n} \mu_{\Sigma}\left(B_{\rho}\left(x_{0}\right)\right)-\frac{2}{\lambda_{\Sigma}} \rho^{1-n} \mu_{\Gamma}\left(B_{\rho}\left(x_{0}\right)\right)
$$

which by (A3) (1) implies

$$
\frac{d}{d \rho}\left(e^{\lambda_{\Sigma}^{-1} \rho} \rho^{1-n} \mu_{\Sigma}\left(\mathrm{B}_{\rho}\left(x_{0}\right)\right)\right) \geqq-\frac{2}{\lambda_{\Sigma}} c\left(x_{0}\right) e^{\lambda_{\Sigma}^{-1} \rho} \rho^{\beta-1}
$$

Integrating we arrive at

$$
e^{\lambda_{\bar{\Sigma}}^{1} \sigma} \sigma^{1-n} \mu_{\Sigma}\left(\mathbf{B}_{\sigma}\left(x_{0}\right)\right) \leqq e^{\lambda_{\Sigma}^{-1} \rho} \rho^{1-n} \mu_{\Sigma}\left(\mathbf{B}_{\rho}\left(x_{0}\right)\right)+\frac{1}{\lambda_{\Sigma}} c\left(x_{0}, \beta\right)\left(\rho^{\beta}-\sigma^{\beta}\right)
$$

for $0<\sigma<\rho \leqq \rho\left(x_{0}\right)-\left|x-x_{0}\right|$.
Hence, we can check as in ([SL], Cor. 17.8) that $\theta^{n-1}\left(\mu_{\Sigma},.\right)$ is uppersemicontinuous and we can apply ([SL], 17.9 (i)) to conclude $\theta_{\Sigma}(x) \geqq 1$ for every $x \in \operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma$. (Recall that $\theta_{\Sigma} \geqq 1 \mu_{\Sigma}-$ a. e. since $\Sigma$ is an integer multiplicity current.) Using this in combination with (A3) (2) we infer
from the definition of $\mu_{\Sigma}$ and $\mu_{\Gamma}$ that

$$
\mu_{\Gamma}(\operatorname{spt} \Sigma \cap \mathbf{W}) \leqq c(\mathbf{W}) \mu_{\Sigma}(\mathbf{W})
$$

for any $\mathrm{W} \subset \mathrm{U} \sim \operatorname{spt} \partial \Gamma$.
Thus we can differentiate $\mu_{\Gamma}$ with respect to $\mu_{\Sigma}$ to obtain

$$
|\delta \Sigma(\mathrm{X})| \leqq \frac{3}{\lambda_{\Sigma}} c(\mathrm{~W}) \int|\mathrm{X}| d \mu_{\Sigma}
$$

for any $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~W} ; \mathbb{R}^{n+k}\right)$, which in turn implies the result.

### 2.6. Remark

(1) Since $\Sigma=\partial T$ in $U \sim \operatorname{spt} \Gamma$ and $\Sigma=-\Gamma$ in $U \sim \operatorname{spt} \partial T$ we have $\left|H_{\Sigma}(x)\right| \leqq 1 / \lambda_{\Sigma}$ for $\mu_{\Sigma}$-a. e. $x \in U \sim(\operatorname{spt} \Gamma \cap \operatorname{spt} \partial T)$.
(2) One easily checks that (A3) holds (with $\beta=1$ ) in case $\Gamma$ locally corresponds to an oriented embedded $\mathrm{C}^{0,1}$-submanifold of $\mathbb{R}^{n+k}$ with multiplicity $m_{\Gamma}$.

### 2.7. Proposition

Let $\mathrm{T} \in \mathrm{I}_{n, \text { loc }}(\mathrm{U})$ be a minimizer of the thread problem with respect to $\Gamma$ satisfying (A1) and assume now that $\mathrm{U} \subset \mathbb{R}^{n+1}$.
Suppose $x_{0}$ is a regular point of $\operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma$ and $\rho<\operatorname{dist}\left(x_{0}, \operatorname{spt} \partial \Gamma\right)$ such that

$$
\begin{gathered}
\Gamma\left\llcorner\mathbf{B}_{\boldsymbol{\rho}}\left(x_{0}\right)=m_{\Gamma} \llbracket \mathbf{M}_{\Sigma} \cap \mathbf{B}_{\rho}\left(x_{0}\right) \rrbracket, m_{\Gamma} \in \mathbb{Z}^{+} \cup\{0\}\right. \\
\partial \mathbf{T}\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)=m_{\partial \mathbf{T}} \llbracket \mathbf{M}_{\Sigma} \cap \mathbf{B}_{\rho}\left(x_{0}\right) \rrbracket, m_{\partial \mathbf{T}} \in \mathbb{Z} \sim\left\{m_{\Gamma}\right\}\right.
\end{gathered}
$$

where $\mathrm{M}_{\Sigma}$ is an ( $n-1$ )-dimensional embedded, oriented $\mathrm{C}^{1}$-submanifold of $\mathbb{R}^{n+1}$.
(1) If $m_{\partial \mathrm{T}} \notin\left[0, m_{\Gamma}\right] \mathbf{M}_{\Sigma}$ is actually of class $\mathrm{C}^{\infty}$ and (for some smaller $\rho>0)$

$$
\begin{equation*}
\mathrm{T} L \mathrm{~B}_{\mathrm{p}}\left(x_{0}\right)=m_{\partial \mathbf{T}} \llbracket \mathbf{M}_{\mathbf{T}} \cap \mathbf{B}_{\mathbf{\rho}}\left(x_{0}\right) \rrbracket+m_{0} \llbracket \mathbf{M}_{0} \cap \mathbf{B}_{\mathrm{\rho}}\left(x_{0}\right) \rrbracket \tag{2.29}
\end{equation*}
$$

where $\mathrm{M}_{\mathrm{T}}$ is an oriented embedded minimal hypersurface of $\mathbb{R}^{n+1}$ with boundary $\mathrm{M}_{\Sigma}, m_{0}$ is a nonnegative integer and $\mathbf{M}_{0}$ is an oriented, embedded real-analytic minimal hypersurface without boundary which contains $\mathbf{M}_{\mathbf{T}}$.
Moreover, the mean curvature vector $\mathbf{H}_{\Sigma}$ of $M$ satisfies $\left|\mathbf{H}_{\Sigma}\right|=1 / \lambda_{\Sigma}\left(\lambda_{\Sigma}\right.$ is the Lagrange multiplier of Theorem 2.3). In fact we have

$$
\begin{equation*}
\int_{\mathrm{M}_{\Sigma}} \operatorname{div}_{\mathrm{M}_{\Sigma}} \mathrm{X} d \mathscr{H}^{n-1}=-\frac{1}{\lambda_{\Sigma}} \int_{\mathrm{M}_{\Sigma}} v_{\partial \mathrm{T}} \cdot \mathrm{X} d \mathscr{H}^{n-1} \tag{2.30}
\end{equation*}
$$

for all $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~B}_{\rho}\left(x_{0}\right) ; \mathbb{R}^{n+1}\right)$, where $v_{\partial \mathrm{T}}$ is the outer unit normal vector of $\mathbf{M}_{\Sigma}$ with respect to $\mathbf{M}_{\mathbf{T}}$.

Note in particular that all regular parts of $\Sigma$ have the same constant mean curvature.
(2) If $0 \leqq m_{\partial \mathrm{T}}<m_{\Gamma}$ and condition (A2) of Theorem (2.3) holds in $\mathbf{U} \sim \overline{\mathbf{B}_{\mathrm{\rho}}\left(x_{0}\right)}, \mathbf{M}_{\Sigma}$ is of class $\mathbf{C}^{1, \alpha}$ for any $\alpha<1$ and the generalized mean curvature vector $H_{\Sigma}$ of $M_{\Sigma}$ satisfies $\left|H_{\Sigma}\right| \leqq \frac{1}{\lambda_{\Sigma}}$.
(3) If $\mathrm{M}_{\Sigma}$ is stationary, i.e. when (A1) is not satisfied T may be supported by several distinct sheets of smooth surfaces with boundary $\mathbf{M}_{\Sigma}$.

Proof. - Suppose first of all that $x_{0} \in \operatorname{spt} \Sigma \sim \operatorname{spt} \Gamma$. In this case we may assume $m_{\partial \mathrm{T}}=m_{\Sigma}>0$ and

$$
\Sigma\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)=m_{\Sigma} \llbracket \mathbf{M}_{\Sigma} \cap \mathbf{B}_{\rho}\left(x_{0}\right) \rrbracket .\right.
$$

From the local decomposition theorem in [WB] we infer

$$
\begin{gather*}
\mathrm{T}\left\llcorner\mathrm{~B}_{\mathrm{\rho}}\left(x_{0}\right)=\sum_{i=1}^{m_{\Sigma}} \mathrm{T}_{i}\left\llcorner\mathrm{~B}_{\mathrm{\rho}}\left(x_{0}\right)\right.\right. \\
\mathbf{M}\left(\mathrm{T}\left\llcorner\mathrm{~B}_{\mathrm{\rho}}\left(x_{0}\right)\right)=\sum_{i=1}^{m_{\Sigma}} \mathbf{M}\left(\mathrm{T}_{i}\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)\right.\right. \tag{2.31}
\end{gather*}
$$

where each $T_{i}$ satisfies $\partial \mathrm{T}_{i}=\frac{1}{m_{\Sigma}} \Sigma$.
We want to show that $x_{0} \in \operatorname{spt} \delta \mathrm{~T}_{i}$ for every $1 \leqq i \leqq m_{\Sigma}$. Since $\partial \mathrm{T}_{i}=\frac{1}{m_{\Sigma}} \Sigma$ and (2.31) holds we can obviously apply Proposition 1.7 (2) again to derive that each $\mathrm{T}_{i}\left\llcorner B_{\rho}\left(x_{0}\right)\right.$ is a minimizer of the thread problem (in $\mathrm{B}_{\mathrm{p} / 2}\left(x_{0}\right)$ say) with respect to $\Gamma=0$.

If $x_{0} \notin \operatorname{spt} \delta \mathrm{~T}_{i}$ we can find a radius $\sigma>0$ such that $\mathrm{T}_{i}\left\llcorner\mathrm{~B}_{\sigma}\left(x_{0}\right)\right.$ is stationary. Hence the usual monotonicity formula holds for $\mathrm{T}_{i}$ at $x_{0}$ (cf. [SL], Chapt. 4). This and the fact that $\partial \mathrm{T}$ is regular in a neighbourhood of $x_{0}$ yields for small enough $\sigma>0$

$$
\frac{\mathbf{M}\left(\mathrm{T}_{i}\left\llcorner\mathbf{B}_{\sigma}\left(x_{0}\right)\right)\right.}{\sigma^{n}}+\frac{\mathbf{M}\left(\partial \mathrm{T}_{i}\left\llcorner\mathbf{B}_{\sigma}\left(x_{0}\right)\right)\right.}{\sigma^{n-1}} \leqq c
$$

where $c$ is independent of $\sigma$.
The fact that $\mathrm{T}_{i}$ locally minimizes mass in the ordinary sense with respect to $\partial \mathrm{T}_{i}$ and the compactness theorem for mass-minimizing currents ([SL], Chapt. 7), then imply the existence of a mass-minimizing tangent
cone $C_{i}$ at $x_{0}$. Obviously $\partial C_{i}=\llbracket T_{x_{0}} \mathbf{M}_{\Sigma} \rrbracket$, where $T_{x_{0}} \mathbf{M}_{\Sigma}$ denotes the oriented tangent space of $M_{\Sigma}$ at $x_{0}$. By ([HS], Chapt. 11) $\mathrm{C}_{i}$ has to be the sum of an oriented $n$-dimensional halfplane of multiplicity one and possibly a hyperplane of arbitrary multiplicity containing this halfplane. Hence $\delta C_{i} \neq 0$.

On the other hand the lower-semicontinuity of the first variation with respect to varifold-convergence and the fact that $T_{i}$ was assumed to be stationary in $\mathrm{B}_{\sigma}\left(x_{0}\right)$ implies the stationarity of $\mathrm{C}_{i}$ and thus leads to a contradiction. Hence we conclude $x_{0} \in \operatorname{spt} \delta \mathrm{~T}_{i}$.

Because each $\mathrm{T}_{i}$ satisfies (A2) and since (A1) holds T we may now apply Theorem 2.3, in particular (2.8) with $\mathrm{T}_{0}$ replaced by $\mathrm{T}_{i}$, to deduce

$$
\begin{equation*}
\delta \mathrm{T}_{i}(\mathrm{X})+\frac{\lambda_{\Sigma}}{m_{\Sigma}} \delta \Sigma(\mathrm{X})=0, \quad 1 \leqq i \leqq m_{\Sigma} \tag{2.32}
\end{equation*}
$$

for every $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~B}_{\mathrm{\rho}}\left(x_{0}\right) ; \mathbb{R}^{n+1}\right)$ ( $\rho$ slightly smaller than above).
Combining (2.10) and (2.32) we obtain

$$
\begin{equation*}
\delta \Sigma(\mathrm{X})=-\frac{1}{\lambda_{\Sigma}} \int v_{\partial \mathrm{T}_{i}} \cdot \mathrm{X} d \mu_{\Sigma}, \quad 1 \leqq i \leqq m_{\Sigma} \tag{2.33}
\end{equation*}
$$

for all $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~B}_{\mathrm{\rho}}\left(x_{0}\right) ; \mathbb{R}^{n+1}\right)$, where the $v_{\hat{\partial} \mathrm{T}_{i}}$ are $\mathscr{H}^{n-1}$-measurable and satisfy $\left|v_{\partial \mathrm{T}_{i}}\right| \leqq 1 \mathscr{H}^{n-1}$-a. e. Standard regularity theory for $\mathrm{C}^{1}$-solutions of the prescribed mean curvature system implies that $\mathbf{M}_{\boldsymbol{\Sigma}} \cap \mathbf{B}_{\rho}\left(x_{0}\right)$ is of class $\mathrm{C}^{1, \alpha}$ for any $\alpha<1$ (and smaller radius $\rho>0$ ). The boundary regularity theory for mass-minimizing currents (cf. [HS]) then yields (again for some smaller $\rho>0$ ) that either

$$
\mathrm{T}\left\llcorner\mathbf{B}_{\mathrm{\rho}}\left(x_{0}\right)=m_{\Sigma} \llbracket \mathbf{M}_{\mathbf{T}} \cap \mathbf{B}_{\rho}\left(x_{0}\right) \rrbracket+m_{0} \llbracket \mathbf{M}_{0} \cap \mathbf{B}_{\rho}\left(x_{0}\right) \rrbracket\right.
$$

where $M_{0}$ is an oriented, embedded real analytic minimal hypersurface without boundary which contains $\mathbf{M}_{\mathrm{T}}$ and $m_{0}$ is a nonnegative integer, ( $\mathrm{M}_{\mathrm{T}}$ like the $\mathrm{M}_{\mathrm{T}_{i}}$ below) or

$$
\mathrm{T}_{i}\left\llcorner\mathrm{~B}_{\mathrm{\rho}}\left(x_{0}\right)=\llbracket \mathbf{M}_{\mathbf{T}_{i}} \cap \mathbf{B}_{\rho}\left(x_{0}\right) \rrbracket, \quad 1 \leqq i \leqq m_{\Sigma}\right.
$$

where each $\mathbf{M}_{\mathrm{T}_{i}}$ is an oriented, embedded minimal $\mathbf{C}^{\mathbf{1 , \alpha}}$-hypersurface with boundary $\mathbf{M}_{\Sigma}$.
In both cases the representation vector $v_{\partial \mathrm{T}_{i}}$ for $\delta \Sigma$ in (2.33) is given by the exterior normal of $\mathbf{M}_{\boldsymbol{\Sigma}}$ with respect to $\mathbf{M}_{\mathbf{T}}$ and $\mathbf{M}_{\mathbf{T}_{i}}$, and is of class $\mathrm{C}^{0, \lambda}$. We furthermore deduce from (2.33) that $v_{\partial \mathrm{T}_{i}}=v_{\partial \mathrm{I}_{j}}$ for $i \neq j$ which by virtue of the Hopf-boundary point lemma for minimal surfaces implies $\mathrm{M}_{\mathrm{T}_{i}}=\mathrm{M}_{\mathrm{T}_{j}}$ for $i \neq j$.

Moreover standard regularity theory implies $\mathbf{M}_{\boldsymbol{\Sigma}} \cap \mathbf{B}_{\boldsymbol{\rho}}\left(x_{0}\right) \in \mathrm{C}^{\mathbf{2 , \alpha}}$. A standard "boot-strapping" argument then leads to the $\mathbf{C}^{\infty}$-regularity of $\mathbf{M}_{\Sigma}$.

Since the above line of argument is applicable at every point in $\mathbf{M}_{\Sigma} \cap \mathbf{B}_{\rho}\left(x_{0}\right)$ (for the original radius $\rho>0$ ) our conclusion also holds for the original ball $\mathrm{B}_{\mathrm{\rho}}\left(x_{0}\right)$.

Let us now assume $x_{0} \in \operatorname{spt} \Gamma$ and $m_{\Gamma} \geqq 1$. Suppose $m_{\partial T} \notin\left[0, m_{\Gamma}\right)$. (If $m_{\partial \mathrm{T}}=m_{\Gamma}, \Sigma\left\llcorner\mathrm{B}_{\mathrm{\rho}}\left(x_{0}\right)=0\right.$.) We again decompose

$$
\mathrm{T}\left\llcorner\mathrm{~B}_{\rho}\left(x_{0}\right)=\sum_{i=1}^{\left|m_{\partial \mathrm{T}}\right|} \mathrm{T}_{i}\left\llcorner\mathrm{~B}_{\rho}\left(x_{0}\right)\right.\right.
$$

where the $T_{i}\left\llcorner\mathbf{B}_{\mathrm{p}}\left(x_{0}\right)\right.$ are additive in mass and satisfy

$$
\partial \mathrm{T}_{i}\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)=\frac{m_{\partial \mathrm{T}}}{\left|m_{\partial \mathrm{T}}\right|} \llbracket \mathbf{M}_{\Sigma} \cap \mathbf{B}_{\rho}\left(x_{0}\right) \rrbracket, \quad 1 \leqq i \leqq m_{\Sigma}\right.
$$

One easily checks that for $1 \leqq i \leqq\left|m_{\partial \mathrm{T}}\right|$ and $\Sigma_{i}=\partial \mathrm{T}_{i}$

$$
\mathbf{M}\left(\Sigma\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)=\mathbf{M}\left(\Sigma_{i}\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)+\mathbf{M}\left(\left(\Sigma-\Sigma_{i}\right)\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right) .\right.\right.\right.
$$

Thus, as above, each $T_{i} L B_{\rho}\left(x_{0}\right)$ is [in view of Prop. 1.7 (2)] a minimizer of the thread problem in $\mathbf{B}_{\rho}\left(x_{0}\right)$ with respect to $\Gamma=0$. [In case $m_{\partial \mathrm{T}}<0$ even T minimizes the thread problem in $\mathrm{B}_{\rho}\left(x_{0}\right)$ with respect to $\Gamma=0$ since then $\mathbf{M}\left(\Sigma\left\llcorner\mathbf{B}_{\boldsymbol{\rho}}\left(x_{0}\right)\right)=\mathbf{M}\left(\partial \mathbf{T}\left\llcorner\mathbf{B}_{\mathbf{\rho}}\left(x_{0}\right)\right)+\mathbf{M}\left(\Gamma\left\llcorner\mathbf{B}_{\mathbf{\rho}}\left(x_{0}\right)\right)\right.\right.\right.$.] As before we show $x_{0} \in \operatorname{spt} \delta \mathrm{~T}_{i}, 1 \leqq i \leqq\left|m_{\partial \mathrm{T}}\right|$ which again enables us to apply (2.8) in order to deduce

$$
\delta \mathrm{T}_{i}(\mathrm{X}) \pm \lambda_{\Sigma} \delta \llbracket \mathrm{M}_{\Sigma} \rrbracket(\mathrm{X})=0, \quad 1 \leqq i \leqq\left|m_{\partial \mathrm{T}}\right|
$$

depending on whether $m_{\partial T}$ is positive or negative. As this identity corresponds to (2.32) the same argument as before can be applied.

It remains to discuss the case where $0 \leqq m_{\partial \mathrm{T}}<m_{\Gamma}$. Define

$$
\begin{gathered}
\mathrm{T}^{\prime}=\mathrm{T}-\mathrm{T}\left\llcorner\mathrm{~B}_{\sigma}\left(x_{0}\right)\right. \\
\Gamma^{\prime}=\Gamma-\Gamma\left\llcorner\mathrm{B}_{\sigma}\left(x_{0}\right)\right. \\
\mathrm{U}^{\prime}=\left(\mathrm{U} \sim \overline{\left.\mathrm{~B}_{\sigma}\left(x_{0}\right)\right)} \cup \mathrm{B}_{\sigma / 2}\left(x_{0}\right)\right.
\end{gathered}
$$

where $\sigma \leqq \rho$ is chosen such that the assumptions (A1) and (A2) still hold in $\mathrm{U}^{\prime}\left[(\mathrm{A} 2)\right.$ was assumed to be valid in $\left.\mathrm{U} \sim \overline{\mathbf{B}_{\rho}\left(x_{0}\right)}\right]$. Since $\partial \mathrm{T}^{\prime}=0$ in $\mathrm{B}_{\sigma / 2}\left(x_{0}\right)$ the conditions of Proposition 1.7 (2) are trivially satisfied for $\mathrm{T}^{\prime}$ and $\Sigma^{\prime}=\partial \mathrm{T}^{\prime}-\Gamma^{\prime}$. Hence $\mathrm{T}^{\prime}$ minimizes the thread problem in $\mathrm{U}^{\prime}$ with respect to $\Gamma^{\prime}$. Applying (2.7) we conclude

$$
\left|\delta \mathrm{T}^{\prime}(\mathrm{X})+\lambda_{\Sigma} \delta \Sigma^{\prime}(\mathrm{X})\right| \leqq \int\left|\mathbf{X} \wedge \vec{\Gamma}^{\prime}\right| d \mu_{\Gamma^{\prime}}
$$

for every $\mathrm{X} \in \mathrm{C}_{\mathrm{c}}^{1}\left(\mathrm{U}^{\prime} \sim \operatorname{spt} \partial \Gamma^{\prime} ; \mathbb{R}^{n+1}\right)$ where $\lambda_{\Sigma}>0$ is determined by

$$
\mathrm{T}^{\prime}\left\llcorner\left(\mathrm{U}^{\prime} \sim \overline{\mathrm{B}_{\mathrm{p}}\left(x_{0}\right)}\right)=\mathrm{T}\left\llcorner\left(\mathrm{U} \sim \overline{\mathrm{~B}_{\mathrm{p}}\left(x_{0}\right)}\right) .\right.\right.
$$

Since $\Sigma^{\prime}\left\llcorner B_{\sigma}\left(x_{0}\right)=-\Gamma^{\prime}\left\llcorner B_{\sigma}\left(x_{0}\right)\right.\right.$ and $T^{\prime}\left\llcorner B_{\sigma}\left(x_{0}\right)=0\right.$ we obtain

$$
\left|\int \operatorname{div}_{M_{\Sigma}} \mathrm{X} d \mathscr{H}^{n-1}\right| \leqq \frac{1}{\lambda_{\Sigma}} \int|\mathrm{X}| d \mathscr{H}^{n-1}
$$

for all $\mathrm{X} \in \mathrm{C}_{\mathrm{c}}^{1}\left(\mathrm{~B}_{\sigma}\left(x_{0}\right) ; \mathbb{R}^{n+1}\right)$.
The above argument works for every point in $\mathbf{M}_{\Sigma} \cap B_{\rho}\left(x_{0}\right)$ with $\lambda_{\Sigma}$ being determined by $\mathrm{T} L\left(\mathrm{U} \sim \overline{\mathbf{B}_{\mathrm{\rho}}\left(x_{0}\right)}\right)$. This completes the proof.

In view of Proposition 2.7 (2) we define the set along which the thread $\Sigma$ "sticks" to the wire $\Gamma$ by

### 2.8. Definition

$$
\mathrm{S}_{\Gamma}=\{x \in \operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma / \exists \rho \in(0, \operatorname{dist}(x, \operatorname{spt} \partial \Gamma))
$$

and

$$
c \in[0,1) \text { s.t. } \partial \mathrm{T}\left\llcorner\mathrm{~B}_{\mathrm{\rho}}\left(x_{0}\right)=c\left(\Gamma\left\llcorner\mathrm{~B}_{\mathrm{\rho}}\left(x_{0}\right)\right)\right\} .\right.
$$

We are going to show that unless $\Sigma$ is stationary away from its boundary the first variation of $\Sigma$ does not vanish at all, except possibly along $S_{\Gamma}$.

### 2.9. Corollary

Let $\mathrm{T} \in \mathrm{I}_{n, \text { loc }}(\mathrm{U})$ be a minimizer of the thread problem with respect to $\Gamma \in \mathrm{I}_{n-1, \text { loc }}(\mathrm{U})$, where $\mathrm{U} \subset \mathbb{R}^{n+1}$.

Suppose reg $\Gamma$ is dense in spt $\Gamma$.
(1) If (A1) of Theorem 2.3 is satisfied we have

$$
\begin{equation*}
\operatorname{spt} \Sigma \sim\left(\mathrm{S}_{\Gamma} \cup \operatorname{spt} \partial \Gamma\right) \subset \operatorname{spt} \delta \Sigma \tag{2.34}
\end{equation*}
$$

(2) If additionally (A2) and (A3) hold we have

$$
\begin{equation*}
\operatorname{spt} \Sigma \sim\left(\mathrm{S}_{\Gamma} \cup \operatorname{spt} \partial \Gamma\right) \subset \operatorname{spt} \delta \mathrm{T} \tag{2.35}
\end{equation*}
$$

Proof. - (1) Let $x_{0} \in \operatorname{spt} \Sigma \sim\left(\mathrm{~S}_{\Gamma} \cup \operatorname{spt} \partial \Gamma\right)$ and suppose there exists a $\rho<\operatorname{dist}\left(x_{0}, \operatorname{spt} \partial \Gamma\right)$ such that

$$
\delta \Sigma(\mathrm{X})=0, \quad \forall \mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~B}_{\mathrm{p}}\left(x_{0}\right) ; \mathbb{R}^{n+1}\right)
$$

where we may assume that $\rho<\operatorname{dist}\left(x_{0}, S_{\Gamma}\right)$. From Allard's regularity theorem ([AW], [SL], Chapt. 5) we see that inside $\mathrm{B}_{\mathrm{p}}\left(x_{0}\right)$ the set reg $\Sigma$ is dense in spt $\Sigma$. Using this and the assumption on reg $\Gamma$ we may assume
without loss of generality that

$$
\begin{gathered}
\partial \mathrm{T}\left\llcorner\mathbf{B}_{\boldsymbol{\rho}}\left(x_{0}\right)=m_{\partial \mathrm{T}} \llbracket \mathbf{M}_{\Sigma} \cap \mathbf{B}_{\mathbf{\rho}}\left(x_{0}\right) \rrbracket\right. \\
\Gamma\left\llcorner\mathbf{B}_{\mathbf{\rho}}\left(x_{0}\right)=m_{\Gamma} \llbracket \mathbf{M}_{\Sigma} \cap \mathbf{B}_{\boldsymbol{\rho}}\left(x_{0}\right) \rrbracket, \quad m_{\Gamma} \in \mathbb{Z}^{+} \cup\{0\}\right.
\end{gathered}
$$

where $m_{\partial \mathrm{T}} \notin\left[0, m_{\Gamma}\right.$ ) since $x_{0} \notin \mathrm{~S}_{\Gamma} . \mathrm{M}_{\Sigma}$ is a real-analytic ( $n-1$ )-dimensional oriented embedded minimal submanifold of $\mathbb{R}^{n+1}$.

On the other hand we obtain, using (A1) and Proposition 2.7 (1), that $\mathbf{M}_{\Sigma}$ has nonzero constant mean curvature, which is a contradiction.
(2) Suppose $x_{0} \in \operatorname{spt} \Sigma \sim\left(\mathrm{~S}_{\Gamma} \cup \operatorname{spt} \partial \Gamma\right)$ and there exists a $\rho<\operatorname{dist}\left(x_{0}\right.$, spt $\left.\partial \Gamma \cup S_{\Gamma}\right)$ such that

$$
\begin{equation*}
\delta \mathrm{T}(\mathrm{X})=0, \quad \forall \mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~B}_{\mathrm{p}}\left(x_{0}\right) ; \mathbb{R}^{n+1}\right) \tag{2.34}
\end{equation*}
$$

Since (A1), (A2) and (A3) hold, we can apply Corollary 2.5 to deduce that the generalized mean curvature of $\Sigma$ is bounded in every open set $\mathrm{W} \Subset \mathrm{U} \sim \operatorname{spt} \partial \Gamma$. Using again Allard's theorem we obtain that inside $\mathbf{B}_{\mathbf{\rho}}\left(x_{0}\right)$ the set reg $\Sigma$ must be dense in spt $\Sigma$. In view of the additional assumption reg $\Gamma=\operatorname{spt} \Gamma$ we may proceed as in part (1) of the proof. Proposition 2.7 (1) [in particular (2.29)] and the divergence theorem for regular minimal submanifolds with boundary then imply $\delta \mathbf{T}\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right) \neq 0\right.$ thus contradicting (2.34).

### 2.10. Corollary

Let $\mathrm{T} \in \mathrm{I}_{n, \text { loc }}(\mathrm{U})$ be a minimizer of the thread problem with respect to $\Gamma \in I_{n-1, \text { loc }}(\mathrm{U})$, where $\mathrm{U} \subset \mathbb{R}^{n+1}$.

Suppose condition (A1) is not satisfied, that is we have

$$
\begin{equation*}
\delta \Sigma(\mathrm{X})=0, \quad \forall \mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{U} \sim \operatorname{spt} \partial \Gamma ; \mathbb{R}^{n+1}\right) \tag{2.35}
\end{equation*}
$$

In case $\operatorname{spt} \Sigma \subset \operatorname{spt} \Gamma$ we furthermore assume that $(\mathrm{reg} \Gamma \cap \operatorname{spt} \Sigma) \sim \mathrm{S}_{\Gamma} \neq \varnothing$.
Suppose we have the following local decomposition of $\Sigma$ : Let $x_{0} \in \operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma, \rho<\operatorname{dist}\left(x_{0}, \operatorname{spt} \partial \Gamma\right)$ and $\Sigma_{0} \in \mathrm{I}_{n-1, \text { loc }}(\mathrm{U})$ satisfy

$$
\begin{align*}
\Sigma\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)=\right. & \Sigma_{0}\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)+\left(\Sigma-\Sigma_{0}\right)\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right) .\right.\right. \\
\mathbf{M}\left(\Sigma\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)=\right. & \mathbf{M}\left(\Sigma_{0}\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)+\mathbf{M}\left(\left(\Sigma-\Sigma_{0}\right)\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)\right.\right.  \tag{2.36}\\
& \partial \Sigma_{0}\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)=0\right.
\end{align*}
$$

Then

$$
\begin{equation*}
\delta \Sigma_{0}(\mathrm{X})=0, \quad \forall \mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~B}_{\mathrm{p}}\left(x_{0}\right) ; \mathbb{R}^{n+1}\right) \tag{2.37}
\end{equation*}
$$

Proof. - Let us suppose $x_{0} \in \operatorname{spt} \delta \Sigma_{0}$.

If $\operatorname{spt} \Sigma \sim \operatorname{spt} \Gamma \neq \varnothing$ we can choose (by Allard's theorem) a point $x_{1} \in \operatorname{reg} \Sigma \sim \operatorname{spt} \Gamma$ and $\sigma<\operatorname{dist}\left(x_{1}, \operatorname{spt} \Gamma\right)$ such that

$$
\begin{equation*}
\Sigma\left\llcorner\mathbf{B}_{\sigma}\left(x_{1}\right)=m_{\Sigma} \llbracket \mathbf{M}_{\Sigma} \cap \mathbf{B}_{\sigma}\left(x_{1}\right) \rrbracket\right. \tag{2.38}
\end{equation*}
$$

where $\mathbf{M}_{\Sigma}$ is an ( $n-1$ )-dimensional oriented, embedded real analytic minimal submanifold of $\mathbb{R}^{n+1}$.
If $\quad \mathrm{spt} \quad \Sigma \subset \mathrm{spt} \Gamma \quad$ we $\quad$ select $\quad x_{1} \in(\operatorname{reg} \Gamma \cap \mathrm{spt} \Sigma) \sim \mathrm{S}_{\Gamma} \quad$ and $\sigma<\operatorname{dist}\left(x_{1}, \operatorname{spt} \partial \Gamma \cup S_{\Gamma}\right)$. Again by Allard's theorem we may assume $x_{1} \in \operatorname{reg} \Sigma$ such that

$$
\begin{gather*}
\partial \mathbf{T L} \mathbf{B}_{\sigma}\left(x_{1}\right)=m_{\partial \mathbf{T}} \llbracket \mathbf{M}_{\Sigma} \cap \mathbf{B}_{\sigma}\left(x_{1}\right) \rrbracket \\
\Gamma\left\llcorner\mathbf{B}_{\sigma}\left(x_{1}\right)=m_{\Gamma} \llbracket \mathbf{M}_{\Sigma} \cap \mathbf{B}_{\sigma}\left(x_{1}\right) \rrbracket, m_{\Gamma} \in \mathbb{Z}^{+} \cup\{0\}\right. \tag{2.39}
\end{gather*}
$$

where $m_{\partial \mathrm{T}} \notin\left[0, m_{\Gamma}\right)$ and $\mathbf{M}_{\Sigma}$ is as in (2.38). [(2.38) is a special case of (2.39).] We may also assume $x_{1} \neq x_{0}$ and choose $\sigma, \rho$ s. t. $\mathrm{B}_{\mathrm{\rho}}\left(x_{0}\right) \cap \mathrm{B}_{\sigma}\left(x_{1}\right)=\varnothing$. (Note that $x_{1} \in \operatorname{spt} \delta \Sigma_{0}$ would imply $x_{1} \notin \operatorname{reg} \Sigma$.)

Define

$$
\begin{gathered}
\Gamma^{\prime}=\Gamma+\left(\Sigma-\Sigma_{0}\right)\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right. \\
\Sigma^{\prime}=\partial \mathbf{T}-\Gamma^{\prime} .
\end{gathered}
$$

We then have

$$
\begin{align*}
& \Sigma^{\prime}\left\llcorner\mathrm{B}_{\rho}\left(x_{0}\right)=\Sigma \Sigma_{0}\left\llcorner\mathrm{~B}_{\rho}\left(x_{0}\right)\right.\right. \\
& \Sigma^{\prime}\left\llcorner\mathrm{B}_{\sigma}\left(x_{1}\right)=\Sigma\left\llcorner\mathrm{B}_{\sigma}\left(x_{1}\right)\right.\right.  \tag{2.40}\\
& \Gamma^{\prime}\left\llcorner\mathrm{B}_{\sigma}\left(x_{1}\right)=\Gamma\left\llcorner\mathrm{B}_{\sigma}\left(x_{1}\right) .\right.\right.
\end{align*}
$$

Using (2.36) and Proposition 1.7 (1) we conclude that T is a minimizer of the thread problem in $\mathbf{B}_{\rho}\left(x_{0}\right) \cup \mathbf{B}_{\sigma}\left(x_{1}\right)$ with respect to $\Gamma^{\prime}$ as new fixed boundary part. Furthermore (2.40) and the choice of $x_{0}$ imply spt $\delta \Sigma^{\prime} \sim \operatorname{spt} \partial \Gamma^{\prime} \neq \varnothing$. Applying Proposition 2.7 (1) to $T$ in $B_{\sigma}\left(x_{1}\right)$ we derive that $\mathbf{M}_{\Sigma}$ has nonzero constant mean curvature which gives a contradiction to (2.39).

### 2.11. Remark

Corollary 2.10 holds in arbitrary codimension if additionally require spt $\delta \mathrm{T} \sim$ spt $\Gamma \neq \varnothing$. Indeed, by virtue of (2.11) we can always find a point $x_{1} \in \operatorname{spt} \delta \mathrm{~T} \sim$ spt $\Gamma$ different from $x_{0}$. Let $\mathbf{B}_{\sigma}\left(x_{1}\right)$ and $\mathbf{B}_{\mathrm{p}}\left(x_{0}\right) \cup$ spt $\Gamma$ be disjoint. As in the proof of Corollary 2.10 T minimizes the thread problem in $B_{\rho}\left(x_{0}\right) \cup B_{\sigma}\left(x_{1}\right)$ with respect to $\Gamma^{\prime}$, where now $\Gamma^{\prime} L B_{\sigma}\left(x_{1}\right)=0$. Let $\mathrm{X}_{0} \in \mathrm{C}_{\mathrm{c}}^{1}\left(\mathrm{~B}_{\rho}\left(x_{0}\right) ; \mathbb{R}^{n+k}\right)$ satisfy $\delta \Sigma_{0}\left(\mathrm{X}_{0}\right) \neq 0$. From (2.1) applied to T and
$\Sigma^{\prime}$ in $B_{\rho}\left(x_{0}\right) \cup B_{\sigma}\left(x_{1}\right)$ we then infer [in view of (2.40) and $\Gamma^{\prime}\left\llcorner B_{\sigma}\left(x_{1}\right)=0\right.$ ]

$$
\left|\delta \mathrm{T}(\mathrm{X}) \delta \Sigma_{0}\left(\mathrm{X}_{0}\right)-\delta \mathrm{T}\left(\mathrm{X}_{0}\right) \delta \Sigma(\mathrm{X})\right| \leqq|\delta \Sigma(\mathrm{X})| \int\left|\mathrm{X}_{0} \Lambda \vec{\Gamma}\right| d \mu_{\Gamma}
$$

for every $\mathrm{X} \in \mathrm{C}_{\mathrm{c}}^{1}\left(\mathrm{~B}_{\sigma}\left(x_{1}\right) ; \mathbb{R}^{n+k}\right)$. The stationarity of $\Sigma$ in $\mathrm{B}_{\sigma}\left(x_{1}\right)$ and the fact that $\delta \Sigma_{0}\left(\mathrm{X}_{0}\right) \neq 0$ contradict the choice of $x_{1} \in \operatorname{spt} \delta \mathrm{~T}$.

The next Corollary of Theorem 2.3 is valid for arbitrary codimension.

### 2.12. Corollary

Let $T \in \mathrm{I}_{n \text {, loc }}(\mathrm{U})$ satisfy the assumptions of Theorem 2.3. Suppose $\Sigma\left\llcorner\mathrm{B}_{\mathrm{\rho}}\left(x_{0}\right)\right.$ decomposes as in (2.36) with $\Sigma_{0}$ satisfying $\delta \Sigma_{0}\left\llcorner\mathrm{~B}_{\mathrm{\rho}}\left(x_{0}\right) \neq 0\right.$.

Then for $\Gamma_{0}=\Gamma+\Sigma-\Sigma_{0}$ the inequality

$$
\begin{equation*}
\left|\delta T(X)+\lambda_{\Sigma} \delta \Sigma_{0}(\mathrm{X})\right| \leqq \int\left|\mathrm{X} \Lambda \vec{\Gamma}_{0}\right| d \mu_{\Gamma_{0}} \tag{2.41}
\end{equation*}
$$

holds for every $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~B}_{\mathrm{p}}\left(x_{0}\right) ; \mathbb{R}^{n+k}\right)$ where $\lambda_{\Sigma}$ is the Lagrange multiplier of Theorem 2.3.

If we additionally assume (A3) (2.41) implies that the generalized mean curvature vector $\mathrm{H}_{\Sigma_{0}}$ of $\Sigma_{0}$ satisfies

$$
\begin{equation*}
\left|H_{\Sigma_{0}}\right| \leqq \frac{1}{\lambda_{\Sigma}} c\left(x_{0}, \rho, \Gamma\right), \quad \mu_{\Sigma}-\text { a. e. } \quad \text { in } B_{\rho}\left(x_{0}\right) \tag{2.42}
\end{equation*}
$$

where $c\left(x_{0}, \rho, \Gamma\right)$ depends on $x_{0}, \rho$ and the constant $c\left(\mathrm{~B}_{\rho}\left(x_{0}\right)\right)$ of condition (A3) (2) (see Cor. 2.5).

### 2.13. Remark

If $U \subset \mathbb{R}^{n+1}$ we can employ Proposition 2.7 to show that $\left\lvert\, H_{\Sigma_{0}}\left\llcorner\operatorname{reg} \Sigma_{0} \left\lvert\, \leqq \frac{1}{\lambda_{\Sigma}}\right.\right.$. Here "regular" refers to the parts of $\Sigma_{0}$ where $\partial \mathrm{T}$ is \right. also regular (as in Prop. 2.7).

Proof of Corollary 2.12. - Taking (2.11) into account we can find a point $x_{1}$ different from $x_{0}$ such that (A2) holds at $x_{1}$. We assumed that

$$
\begin{equation*}
\delta \Sigma_{0}\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right) \neq 0 .\right. \tag{2.43}
\end{equation*}
$$

We now choose $\sigma \in\left(0, \operatorname{dist}\left(x_{1}\right.\right.$, spt $\left.\partial \Gamma\right)$ ) such that $B_{\sigma}\left(x_{1}\right) \cap B_{\rho}\left(x_{0}\right)=\varnothing$. Let $\Gamma^{\prime}$ and $\Sigma^{\prime}$ be defined as in the proof of Corollary 2.10. T then minimizes the thread problem in $\mathrm{B}_{\sigma}\left(x_{1}\right) \cup \mathrm{B}_{\mathrm{p}}\left(x_{0}\right)$ with respect to $\Gamma^{\prime}$ and $\Sigma^{\prime}=\tilde{c} \mathrm{~T}-\Gamma^{\prime}$.

Furthermore (A1) and (A2) hold in $\mathrm{B}_{\mathrm{\sigma}}\left(x_{1}\right) \cup \mathrm{B}_{\mathrm{\rho}}\left(x_{0}\right)$ [due to assumption (2.43), the choice of $x_{1}$ and the definition of $\left.\Sigma^{\prime}\right]$. Theorem 2.3 then yields

$$
\left|\delta T(X)+\lambda_{\Sigma} \delta \Sigma^{\prime}(\mathrm{X})\right| \leqq \int\left|\mathrm{X} \wedge \vec{\Gamma}^{\prime}\right| d \mu_{\mathrm{r}^{\prime}}
$$

for every $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{~B}_{\mathrm{\rho}}\left(x_{0}\right) \cup \mathrm{B}_{\sigma}\left(x_{1}\right) ; \mathbb{R}^{n+k}\right)$ which reduces to

$$
\left|\delta T(X)+\lambda_{\Sigma} \delta \Sigma_{0}(X)\right| \leqq \int\left|X \wedge \vec{\Gamma}_{0}\right| d \mu_{\Gamma_{0}}
$$

for every $\mathrm{X} \in \mathrm{C}_{\mathrm{c}}^{1}\left(\mathrm{~B}_{\rho}\left(x_{0}\right) ; \mathbb{R}^{n+k}\right)$.
Let us now assume that $\Gamma$ satisfies assumption (A3). From Corollary 2.5 we infer

$$
\mid \mathrm{H}_{\Sigma}\left\llcorner\mathbf{B}_{\rho}(x) \mid \leqq c\left(x_{0}, \rho, \Gamma\right), \quad \mu_{\Sigma} \text {-a.e. in } \mathbf{B}_{\rho}\left(x_{0}\right) .\right.
$$

[We denote all constants depending on $x_{0}, \rho, \Gamma$ by $c\left(x_{0}, \rho, \Gamma\right)$.] Hence we can use the monotonicity formula [for $\Sigma\left\llcorner\mathbf{B}_{\mathrm{\rho}}\left(x_{0}\right)\right.$ ] and ([SL], 17.9) to verify that $\Sigma$ satisfies (A3) (with $\beta=1$ ) in $\mathbf{B}_{\boldsymbol{\rho}}\left(x_{0}\right)$. Applying the same argument as in the proof of Corollary 2.5 we derive
$\mu_{\Sigma}\left(\mathbf{B}_{\mathrm{\rho}}\left(x_{0}\right) \cap \operatorname{spt} \Sigma_{0} \cap \mathbf{W}\right) \leqq c\left(x_{0}, \rho, \Gamma\right) \mu_{\Sigma_{0}}\left(\mathbf{B}_{\mathrm{\rho}}\left(x_{0}\right) \cap \mathbf{W}\right), \quad \forall \mathbf{W} \subset \mathbf{B}_{\mathrm{\rho}}\left(x_{0}\right)$
(using the definition of $\mu_{\Sigma}, \mu_{\Sigma_{0}}$ and the fact that the monotonicity formula for $\Sigma$ yields $\theta_{\Sigma} \leqq c\left(x_{0}, \rho, \Gamma\right) \mathscr{H}^{n-1}$-a. e. in $\left.\mathbf{B}_{\rho}\left(x_{0}\right)\right)$. Similarly we obtain in view of $\mu_{\Gamma_{0}} \leqq \mu_{\Gamma}+\mu_{\Sigma}+\mu_{\Sigma_{0}}$

$$
\begin{aligned}
\mu_{\Gamma_{0}}\left(\mathbf{B}_{\rho}\left(x_{0}\right) \cap \operatorname{spt}\right. & \left.\Sigma_{0} \cap \mathbf{W}\right) \\
& \leqq c\left(x_{0}, \rho, \Gamma\right) \mu_{\Sigma}\left(\mathbf{B}_{\rho}\left(x_{0}\right) \cap \operatorname{spt} \Sigma_{0} \cap \mathbf{W}\right)+\mu_{\Sigma_{0}}\left(\mathbf{B}_{\rho}\left(x_{0}\right) \cap \mathbf{W}\right)
\end{aligned}
$$

for every $\mathbf{W} \subset \mathbf{B}_{\rho}\left(x_{0}\right)$.
Altogether we conclude
$\mu_{\Gamma_{0}}\left(\mathrm{~B}_{\mathrm{p}}\left(x_{0}\right) \cap \mathrm{spt} \Sigma_{\mathrm{o}} \cap \mathbf{W}\right)$

$$
\leqq c\left(x_{0}, \rho, \Gamma\right) \mu_{\Sigma_{0}}\left(\mathbf{B}_{\mathrm{\rho}}\left(x_{0}\right) \cap \mathrm{W}\right), \quad \forall \mathrm{W} \subset \mathbf{B}_{\mathrm{\rho}}\left(x_{0}\right)
$$

which enables us to derive (2.42) from (2.41) as in the proof of Corollary 2.5 by differentiating $\mu_{\Gamma_{0}}$ with respect to $\mu_{\Sigma_{0}}$.

## 3. PARTIAL REGULARITY FOR THE TWO DIMENSIONAL THREAD PROBLEM

### 3.1. Theorem

Let $\mathrm{T} \in \mathrm{I}_{2, \text { loc }}(\mathrm{U})$ be a minimizer of the thread problem with respect to $\Gamma \in \mathrm{I}_{1, \mathrm{loc}}(\mathrm{U})$, where $\mathrm{U} \subset \mathbb{R}^{3}$.

Suppose

$$
\delta \Sigma(X)=0
$$

for every $\mathrm{X} \in \mathrm{C}_{c}^{1}\left(\mathrm{U} \sim \operatorname{spt} \partial \Gamma ; \mathbb{R}^{3}\right)$.
In case spt $\Sigma \subset \operatorname{spt} \Gamma$ we furthermore assume

$$
(\operatorname{reg} \Gamma \cap \operatorname{spt} \Sigma) \sim \mathrm{S}_{\Gamma} \neq \varnothing
$$

Then

$$
\begin{equation*}
\operatorname{sing} \Sigma \sim \operatorname{spt} \partial \Gamma=\varnothing \tag{3.1}
\end{equation*}
$$

### 3.2. Remark

Theorem 3.1. suggests sufficient conditions for assumption (A1) to hold.
In the simplest case (see also [DHL]), for instance if $\Gamma=m_{\Gamma} \llbracket \gamma \rrbracket$ where $\gamma$ is a rectifiable Jordan arc in $\mathbb{R}^{3}$ with endpoints $P_{1}$ and $P_{2}$ then (A1) is satisfied if we assume

$$
\begin{equation*}
\mathbf{M}(\Sigma)>m_{\Gamma} \operatorname{dist}\left(\mathbf{P}_{1}, \mathbf{P}_{2}\right) . \tag{3.2}
\end{equation*}
$$

Proof of Theorem 3.1. - By exploiting the special structure of one dimensional stationary varifolds ([AA], Chapt. 3) we obtain that for every $x_{0} \in \operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma$ there exists a $\rho<\operatorname{dist}\left(x_{0}, \operatorname{spt} \partial \Gamma\right)$ and a positive integer $\mathrm{N}\left(x_{0}\right)$ such that

$$
\Sigma\left\llcorner\mathrm{B}_{\mathrm{\rho}}\left(x_{0}\right)=\sum_{i=1} m_{i} \llbracket l_{i} \cap \mathbf{B}_{\rho}\left(x_{0}\right) \rrbracket\right.
$$

where $m_{i} \in \mathbb{Z}^{+}$and the $l_{i}$ denote piecewise linear curves through $x_{0}$ (singular only at $x_{0}$ ) without endpoints in $\mathrm{B}_{\mathrm{p}}\left(x_{0}\right)$. By virtue of Corollary 2.10, any local decomposition of $\Sigma$ which does not introduce boundary points consists of stationary components only. Obviously this implies

$$
\Sigma\left\llcorner\mathrm{B}_{\mathrm{p}}\left(x_{0}\right)=m \llbracket l \cap \mathrm{~B}_{\mathrm{p}}\left(x_{0}\right) \rrbracket\right.
$$

where $m \in \mathbb{Z}^{+}$and $l$ is a line through $x_{0}$.
Thus every connected component of spt $\Sigma$ has to be a line segment.

### 3.3. Remark

The Theorem holds for arbitrary codimension if we additionally require $\operatorname{spt} \delta \mathrm{T} \sim \operatorname{spt} \Gamma \neq \varnothing$ (as in Remark 2.11).

### 3.4. Theorem

Let $\mathrm{T} \in \mathrm{I}_{2, \text { loc }}(\mathrm{U})$ satisfy the assumptions of Corollary 2.5.
Then for every point $x_{0} \in \operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma$ there exists a radius $\rho<\operatorname{dist}\left(x_{0}\right.$, spt $\left.\partial \Gamma\right)$ and a positive integer $\mathrm{N}\left(x_{0}\right)$ such that

$$
\begin{equation*}
\Sigma\left\llcorner\mathrm{B}_{\mathrm{p}}\left(x_{0}\right)=\sum_{i=1}^{\mathrm{N}\left(x_{0}\right)} m_{i} \llbracket \sigma_{i} \cap \mathbf{B}_{\mathrm{p}}\left(x_{0}\right) \rrbracket\right. \tag{3.3}
\end{equation*}
$$

where $m_{i} \in \mathbb{Z}^{+}$and each $\sigma_{i}$ is an embedded oriented $\mathbb{C}^{1,1}$-curve through $x_{0}$ without endpoints in $\mathrm{B}_{\mathrm{p}}\left(x_{0}\right)$. Moreover all $\sigma_{i}$ have the same tangent at $x_{0}$.
Proof. - Let $x_{0} \in \operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma, \rho \in\left(0, \operatorname{dist}\left(x_{0}, \operatorname{spt} \partial \Gamma\right)\right)$. The decomposition theorem of ([FH], 4.2.25) implies

$$
\begin{gather*}
\Sigma\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)=\sum_{i=1}^{\infty} \llbracket \sigma_{i} \cap \mathbf{B}_{\rho}\left(x_{0}\right) \rrbracket\right.  \tag{3.4}\\
\mathbf{M}\left(\Sigma\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)=\sum_{i=1}^{\infty} L\left(\sigma_{i} \cap \mathbf{B}_{\rho}\left(x_{0}\right)\right)\right.
\end{gather*}
$$

where each $\sigma_{i}$ is an embedded Lipschitz curve parametrized by arc length and $L$ denotes the length of a curve.

Corollary 2.12 (in particular 2.42)

$$
\mid \mathbf{H}\left(\sigma_{i}\right)\left\llcorner\mathbf{B}_{\rho_{0}}\left(x_{0}\right) \mid \leqq c\left(x_{0}, \rho_{0}, \Gamma\right), \quad \mu_{\Sigma}-\right.\text { a. e. }
$$

where $\rho_{0}<\operatorname{dist}\left(x_{0}, \operatorname{spt} \partial \Gamma\right)$ is fixed. $\mathrm{H}\left(\sigma_{i}\right)$ denotes the generalized curvature of $\left[\sigma_{i}\right]$. Using ([SL], Lemma 19.1) we may choose some $\rho \leqq \rho_{0}$ small enough depending on $c\left(x_{0}, \rho_{0}, \Gamma\right)$ such that $\overline{B_{p}\left(x_{0}\right)}$ does not contain any closed $\sigma_{i}$.
Moreover each $\sigma_{i}$ has to be of class $\mathbf{C}^{\mathbf{1 , 1}}$. Indeed, since the $\sigma_{i}$ are parametrized by arc length, the first variation formula for $\llbracket \sigma_{i} \rrbracket$ reduces to

$$
\int \sigma_{i}^{\prime} \eta^{\prime} d t=\int \mathbf{H}\left(\sigma_{i}\right) \eta d t
$$

for all $\eta \in \mathrm{C}_{c}^{0,1}\left(0, \mathrm{~L}\left(\sigma_{i} \cap \mathbf{B}_{\mathrm{p}}\left(x_{0}\right)\right)\right)$.
Since $x_{0} \in \operatorname{spt} \Sigma$ we can find for every $\rho_{j} \leqq \rho(j \geqq 1)$ a curve $\sigma_{j}$ intersecting $\mathrm{B}_{\rho_{j}}\left(x_{0}\right)$. Because there are no closed $\sigma_{j}$ inside $\overline{\mathbf{B}_{\rho}\left(x_{0}\right)}$, each $\sigma_{j}$ has to intersect $\partial \mathrm{B}_{\rho}\left(x_{0}\right)$ at least twice, which implies (by the continuity of the $\sigma_{j}$ )

$$
\mathbf{L}\left(\sigma_{j} \cap \mathbf{B}_{\mathrm{p}}\left(x_{0}\right)\right) \geqq \rho
$$

for large enough $j$. Hence (3.4) and the fact that $\mathbf{M}\left(\Sigma\left\llcorner B_{\rho}\left(x_{0}\right)\right)<\infty\right.$ imply that there are only finitely many $\sigma_{j}$ contained in $B_{\rho}\left(x_{0}\right)$. If we choose $\rho$ small enough we can even ensure that there exists an $N\left(x_{0}\right) \in \mathbb{Z}^{+}$ such that

$$
\Sigma\left\llcorner\mathrm{B}_{\mathrm{p}}\left(x_{0}\right)=\sum_{i=1}^{\mathrm{N}\left(x_{0}\right)} m_{i} \llbracket \sigma_{i} \cap \mathrm{~B}_{\mathrm{\rho}}\left(x_{0}\right) \rrbracket,\right.
$$

where each $\sigma_{i}$ contains $x_{0}$ and coinciding curves are counted with multiplicities.

We can the employ the decomposition argument of Corollary 2.13 to conclude that the tangents of all $\sigma_{i}$ at $x_{0}$ have to agree. Otherwise we could find a decomposition of $\Sigma$ consisting of components which are not even differentiable at $x_{0}$.

We are now able to prove a monotonicity formula for T at points of $\operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma$.

### 3.5. Proposition

Let T satisfy the assumptions of Theorem 3.4. Let $\Gamma$ be supported in an oriented embedded Jordan arc of class $\mathbf{C}^{1, \alpha}$.

Then for every $x_{0} \in \operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma$ we can find a radius $\rho\left(x_{0}\right)<\operatorname{dist}\left(x_{0}\right.$, spt $\left.\partial \Gamma\right)$ such that for every $0<\sigma<\rho \leqq \rho\left(x_{0}\right)$

$$
\begin{align*}
\rho^{-2} \mathbf{M}\left(T\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)\right. & -\sigma^{-2} \mathbf{M}\left(\mathbf{T}\left\llcorner\mathbf{B}_{\sigma}\left(x_{0}\right)\right)\right.  \tag{3.5}\\
& \geqq \int_{\mathbf{B}_{\rho}\left(x_{0}\right) \sim \mathbf{B}_{\sigma}\left(x_{0}\right)} r^{-2}\left(1-\left|\nabla^{\mathrm{T}} r\right|\right) d \mu_{\mathrm{T}}-\frac{c}{\alpha}\left(\rho^{\alpha}-\sigma^{\alpha}\right)
\end{align*}
$$

where $c$ depends only on the $\mathrm{C}^{1, \alpha}$-norm and the multiplicity of $\Gamma$.
Note in particular that (3.5) is independent of $\Sigma$.
Proof. - Let $x_{0}=0$. If $\rho(0)$ is small enough we can, for $\mathscr{L}^{1}$-a.e. $\rho<\rho(0)$, i. e. for those $\rho$ s.t. $\partial\left(\Gamma\left\llcorner\mathbf{B}_{\rho}\left(x_{0}\right)\right)\right.$ is well defined (note that the following argument holds for arbitrary dimension), find a bi-Lipschitzhomeomorphism $g_{\rho}$ in $\mathrm{B}_{\rho}(0)$ satisfying $\left.g_{\rho}\right|_{\partial \mathrm{B}_{\mathrm{p}}(0)}=\mathrm{id}$ and

$$
g_{\rho \sharp}\left(\Gamma\left\llcorner\mathbf{B}_{\rho}(0)\right)=0 \# \partial\left(\Gamma\left\llcorner\mathbf{B}_{\rho}(0)\right)\right.\right.
$$

where $0 \# \partial\left(\Gamma\left\llcorner B_{\rho}(0)\right)\right.$ denotes the cone over $\partial\left(\Gamma\left\llcorner B_{\rho}(0)\right)\right.$. (We can, for instance, look at $\operatorname{spt}\left(\Gamma\left\llcorner\mathbf{B}_{\rho}(0)\right)\right.$ as a graph over $\operatorname{spt}\left(0 \# \partial\left(\Gamma\left\llcorner B_{\rho}(0)\right)\right)\right.$.) For $t \in[0,1]$ let $h_{\rho}(t, x)=\operatorname{tg}_{\rho}(x)+(1-t) x$ and define

$$
\mathrm{T}_{\mathrm{p}}=-h_{\mathrm{p} ;}\left(\left[(0,1) \rrbracket \times\left(\Gamma\left\llcorner\mathbf{B}_{\mathrm{p}}(0)\right)\right) .\right.\right.
$$

From ([SL], 26.23) we obtain
$\begin{aligned} \mathbf{M}\left(\mathrm{T}_{\rho}\right) \leqq\left(1+\sup _{\mathbf{B}_{\rho}}\left|\mathrm{D} g_{\rho}\right|\right) \operatorname{dist}(\operatorname{spt}( & \Gamma\left\llcorner\mathbf{B}_{\rho}(0)\right), \\ & \operatorname{spt}\left(0 \geqslant \partial\left(\Gamma\left\llcorner\mathbf{B}_{\rho}(0)\right)\right)\right) \cdot \mathbf{M}\left(\Gamma\left\llcorner\mathbf{B}_{\rho}(0)\right)\right.\end{aligned}$
which, since spt $\Gamma \in \mathbf{C}^{1, \alpha}$, implies

$$
\begin{equation*}
\mathbf{M}\left(\mathrm{T}_{\rho}\right) \leqq c \rho^{n+\alpha} \tag{3.6}
\end{equation*}
$$

where $c$ depends on the $\mathrm{C}^{1, \alpha}$-norm and the multiplicity of $\Gamma$.
Suppose now that

$$
\mu_{\mathrm{T}}\left(\partial \mathbf{B}_{\rho}(0)\right)=0
$$

and that the slices $\langle\mathrm{T}, r, \rho\rangle$ and $\partial\left(\partial \mathrm{T}\left\llcorner\mathrm{B}_{\rho}(0)\right)\right.$ are defined. (This holds for $\mathscr{L}^{1}$-a. e. $\rho$.)
Define

$$
\mathrm{S}_{\mathrm{\rho}}=0 \geqslant\langle\mathrm{~T}, r, \rho\rangle+\mathrm{T}_{\rho}+\mathrm{T} L\left(\mathrm{U} \sim \overline{\mathrm{~B}_{\rho}(0)}\right) .
$$

We obviously have for every $\varepsilon>0$

$$
\operatorname{spt}\left(S_{\rho}-T\right) \subset B_{\rho+\varepsilon}(0)
$$

Furthermore

$$
\begin{aligned}
& \partial(0 *\langle\mathrm{~T}, r, \rho\rangle)=\langle\mathrm{T}, r, \rho\rangle+0 * \partial\left(\Sigma\left\llcorner\mathrm{~B}_{\mathrm{p}}(0)\right)+0 * \partial\left(\Gamma\left\llcorner\mathrm{~B}_{\mathrm{p}}(0)\right)\right.\right. \\
& \partial\left(\mathrm{T}\left\llcorner\left(\mathrm{U} \sim \mathrm{~B}_{\mathrm{p}}(0)\right)\right)=\partial \mathrm{T}\left\llcorner\left(\mathrm{U} \sim \overline{\mathrm{~B}_{\mathrm{p}}(0)}\right)-\langle\mathrm{T}, r, \rho\rangle\right.\right. \\
& \partial \mathrm{T}_{\mathrm{p}}=\Gamma\left\llcorner\mathrm{B}_{\mathrm{p}}(0)-0 \geqslant \partial\left(\Gamma\left\llcorner\mathrm{~B}_{\rho}(0)\right)\right.\right.
\end{aligned}
$$

which gives

$$
\partial \mathrm{S}_{\mathrm{\rho}}-\Gamma=0 \# \partial\left(\Sigma\left\llcorner\mathbf{B}_{\rho}(0)\right)+\Sigma\left\llcorner\left(\mathrm{U} \sim \overline{\mathbf{B}_{\rho}(0)}\right) .\right.\right.
$$

Hence for every $\varepsilon>0$ we have (set $B_{\rho}=B_{\rho}(0)$ )

$$
\mathbf{M}_{\mathbf{B}_{\boldsymbol{\rho}}+\varepsilon}\left(\partial \mathbf{S}_{\boldsymbol{\rho}}-\Gamma\right)=\mathbf{M}_{\mathbf{B}_{\boldsymbol{\rho}}}\left(0 \# \partial\left(\Sigma\left\llcorner\mathbf{B}_{\boldsymbol{\rho}}\right)\right)+\mathbf{M}_{\mathbf{B}_{\boldsymbol{p}}+\varepsilon} \sim \mathbf{B}_{\boldsymbol{p}}\left(\Sigma\left\llcorner\left(\mathrm{U} \sim \overline{\mathbf{B}_{\boldsymbol{\rho}}}\right)\right)\right.\right.
$$

Using the special local structure of one dimensional threads given in (3.3) of Theorem 3.4 which implies that for small enough $\rho 0 \geqslant \partial\left(\Sigma\left\llcorner B_{p}\right)\right.$ is supported in a finite number of line segments we obtain

$$
\mathbf{M}_{\mathbf{B}_{\boldsymbol{\rho}+\varepsilon}}\left(\partial \mathbf{S}_{\boldsymbol{\rho}}-\Gamma\right) \leqq \mathbf{M}_{\mathbf{B}_{\boldsymbol{\rho}}+\varepsilon}(\partial \mathbf{T}-\Gamma)
$$

Applying Proposition 1.3 we derive

$$
\mathbf{M}_{\mathbf{B}_{\boldsymbol{\rho}+\varepsilon}(0)}(\mathrm{T}) \leqq \mathbf{M}_{\mathbf{B}_{\boldsymbol{\rho}+\varepsilon}(0)}\left(\mathbf{S}_{\boldsymbol{\rho}}\right) .
$$

Since $\mu_{T}\left(B_{\rho}(0)\right)=0$ we can let $\varepsilon$ tend to 0 to conclude

$$
\mathbf{M}\left(\mathbf{T}\left\llcorner\mathbf{B}_{\boldsymbol{p}}(0)\right) \leqq \mathbf{M}(0 \#\langle\mathbf{T}, r, \rho\rangle)+\mathbf{M}\left(\mathbf{T}_{\mathfrak{p}}\right)\right.
$$

which by (3.6) and the definition of $0 甘\langle T, r, \rho\rangle$ implies

$$
\mathbf{M}\left(\mathrm{T}\left\llcorner\mathbf{B}_{\rho}(0)\right) \leqq \frac{\rho}{2} \mathbf{M}(\langle\mathrm{~T}, r, \rho\rangle)+c \rho^{2+\alpha} .\right.
$$

The coarea-formula yields for $\mathscr{L}^{1}$-a. e. $\rho>0$

$$
\rho^{-2} \mathbf{M}(\langle T, r, \rho\rangle)=\rho^{-2} \frac{d}{d \rho} \mathbf{M}\left(T\left\llcorner\mathbf{B}_{\rho}(0)\right)-\frac{d}{d \rho} \int_{\mathbf{B}_{\rho}(0)} r^{-2}\left(1-\left|\nabla^{\mathrm{T}} r\right|\right) d \mu .\right.
$$

Hence we obtain in the usual way

$$
\frac{d}{d \rho}\left(\rho^{-2} \mathbf{M}\left(\mathbf{T}\left\llcorner\mathbf{B}_{\rho}(0)\right)\right) \geqq \frac{d}{d \rho} \int_{\mathbf{B}_{\rho}} r^{-2}\left(1-\left|\nabla^{\mathrm{T}} r\right|\right) d \mu_{\mathrm{T}}-2 c \rho^{\alpha-1}\right.
$$

The result follows by integration.

### 3.6. Remark

The monotonicity formula remains valid if we assume that in a neighbourhood of each point $x_{0} \in \operatorname{spt} \Gamma \Gamma$ is supported in a finite number of $C^{1, \alpha}$-arcs which intersect at $x_{0}$. We only have to check that an estimate like (3.6) still holds in this case for some current $T_{\rho}$ connecting $\Gamma\left\llcorner B_{\rho}\left(x_{0}\right)\right.$ to the cone over $\partial\left(\Gamma\left\llcorner\mathrm{B}_{\mathrm{p}}\left(x_{0}\right)\right)\right.$.

### 3.7. Corollary

Let T and $\Gamma$ satisfy the assumptions of Theorem 3.4. Then at each point $x_{0} \in \operatorname{spt} \Sigma \sim \operatorname{spt} \partial \Gamma$ there exists a mass-minimizing tangent cone C (with "vertex" 0) such that

$$
\partial \mathrm{C}=m_{\Sigma}\left(x_{0}\right) \llbracket l_{\Sigma} \rrbracket+m_{\Gamma} \llbracket l_{\Gamma} \rrbracket
$$

where $l_{\Sigma}, l_{\Gamma}$ are the tangent directions of $\Sigma$ and $\Gamma$ at $x_{0}, m_{\Gamma}$ is the multiplicity of $\Gamma$ and $m_{\Sigma}\left(x_{0}\right)=\sum_{i=1}^{\mathrm{N}\left(x_{0}\right)} m_{i}$,

Proof. - As in ([SL], Chapt. 7).

### 3.8. Remark

$\partial\left(C\left\llcorner B_{1}(0)\right)\right.$ is given by a combination of great circles and great circle segments with multiplicities which has boundary

$$
m_{\Sigma}\left(x_{0}\right) \llbracket l_{\Sigma} \cap \partial \mathbf{B}_{1}(0) \rrbracket+m_{\Gamma} \llbracket l_{\Gamma} \cap \partial \mathbf{B}_{1}(0) \rrbracket .
$$

Note that in view of the interior regularity of $C$ the curves involved are disjoint except at the endpoints of $l_{\Sigma} \cap B_{1}(0)$ and $l_{\Gamma} \cap B_{1}(0)$.

If in particular $x_{0} \in \operatorname{spt} \Sigma \sim \operatorname{spt} \Gamma$, the tangent cone $C$ either will be supported in the union of halfplanes with boundary $l_{\Sigma}$ or is a plane
containing $l_{\Sigma}$ with some multiplicity $p$ on one side of $l_{\Sigma}$ and $m_{\Sigma}\left(x_{0}\right)+p$ on the other side of $l_{\Sigma}$.
If $x_{0} \in \operatorname{spt} \Gamma \sim \operatorname{spt} \partial \Gamma$ the cone $C$ may have (possibly in addition to full planes and halfplanes bounded by $l_{\Sigma}$ and/or $l_{\Gamma}$ ) decomposable components supported in the union of the two oriented regions into which the plane spanned by $l_{\Sigma}$ and $l_{\Gamma}$ is divided by the lines $l_{\Sigma}$ and $l_{\Gamma}$.
