# THE MACKEY-ARENS AND HAHN-BANACH THEOREMS 

## FOR SPACES OVER VALUED FIELDS

## Jerzy Kakol

Astract. Characterizations of the spherical completeness of a non-archimedean complete non-trivially valued field in terms of classical theorems of Functional Analysis are obtained.

1991 Mathematics subject classification : 46 S10

## Spherical completeness

Throughout this paper $K=(K,||$.$) will denote a non-archimedean complete valued$ field with a non-trivial valuation $|$.$| . It is well-known that the absolute value function$ $|\cdot|$ of the field of the real numbers $\mathbb{R}$ or the complex numbers. $\mathbb{C}$ satisfies the following properties :
(i) $0 \leq|x|,|x|=0$ iff $x=0$,
(ii) $|x+y| \leq|x|+|y|$,
(iii) $|x y|=|x||y|, x, y \in \mathbb{R}$ or $x, y \in \mathbb{C}$.

If $K$ is a field, then by a valuation on $K$ we will mean a map $|$.$| of K$ into $\mathbb{R}$ satisfying the above properties; in this case $(K,||$.$) will be called a valued field. We will assume$ that $K$ is complete with respect to the natural metric of $K$.

It turns out that if $K$ is not isomorphic to $\mathbb{R}$ or $\mathbb{C}$, then its valuation satisfies the following strong triangle inequality, cf. e.g. [12],
(ii') $|x+y| \leq \max \{|x|,|y|\}, x, y \in K$.
A valued field $K$ whose valuation satisfies (ii') will be called non-archimedean and its valuation non-archimedean.

Let us first recall the following well-known result of Cantor
Theorem 0 Let $(X, \rho)$ be a metric space. Then it is complete iff every shrinking sequence of closed balls whose radii tend to zero has non-empty intersection.

Consider the set $\mathbb{N}$ of the natural numbers endowed with the following metric $\rho$ defined by $\rho(m, n)=0$ if $m=n$ and $1+\max \left(\frac{1}{m}, \frac{1}{n}\right)$ if $m \neq n$.

Then the metric $\rho$ is non-archimedean, i.e. $\rho(m, n)=0 \quad$ iff either $m=n$, or $\rho(m, n) \leq \max \{\rho(m, k), \rho(k, n)\}$, for all $m, n, k \in \mathbb{N}$.

It is easy to see that every shrinking sequence of balls in $\mathbb{N}$ whose radii tend to zero has non-empty intersection; note that every ball whose radius is smaller than 1 contains exactly one point. On the other hand, the balls $B_{1+\frac{1}{1}}(1), B_{1+\frac{1}{2}}(2), \ldots$, form a decreasing sequence and their intersection is empty. This suggests the following, see Ingleton [3] :

A non-archimedean metric space ( $X, \rho$ ) will be said to be spherically complete if the intersection of every shrinking sequence of its balls is non-empty.

Clearly spherical completeness implies completeness; the converse fails : The space $(\mathbb{N}, \rho)$ is complete but not spherically complete. We refer to [11] and [12] for more infomation concerning this property.

Theorem 1 Let $(X, \rho)$ be a non-archimedean metric space. Then $(X, \rho)$ is spherically complete iff given an arbitrary family $\mathcal{B}$ of balls in $X$, no two of which are disjoint, then the intersection of the elements of $\mathcal{B}$ is non-empty.

The aim of this note is to collect a few characterizations of the spherical completeness of $K$ in terms of the Mackey-Arens, Hahn-Banach and weak Schauder basis theorems, respectively, see [5], [6], [7], [12].

## The Mackey-Arens and Hahn-Banach theorems

The terms "K-space", "topology"," seminorm or norm" will mean a Hausdorff locally convex space (lcs) over $K$, a locally convex topology (in the sense of Monna) and a nonarchimedean seminorm (norm), respectively. A seminorm on a vector space $E$ over $K$ is non-archimedean if it satisfies condition (ii'). Clearly the topology $\tau$ generated by a norm is locally convex. Recall that a topological vector space (tvs) $E=(E, \tau)$ over $K$ is locally convex [10] if $\tau$ has a basis of absolutely convex neighbourhoods of zero. A subset $U$ of $E$ is absolutely convex (in the sense of Monna [10]) if $\alpha x+\beta y \in U$, whenever $x, y \in U$, $\alpha, \beta \in,|\alpha| \leq 1,|\beta| \leq 1$. For the basic notions and properties concerning tvs and lcs over $K$ we refer to [10], [11], [13].

A locally convex (lc) topology $\gamma$ on ( $E, \tau$ ) is called compatible with $\tau$, if $\tau$ and $\gamma$ have the same continuous linear functionals; $(E, \tau)^{*}=(E, \gamma)^{*} .(E, \tau)$ is dual-separating if $(E, \tau)^{*}$ separates points of $E$. If $G$ is a vector subspace of $E, \tau \mid G$ and $\tau / G$ denote the topology $\tau$ restricted to $G$ and the quotient topology of the quotient space $E / G$, respectively. If $\alpha$ is a finer l.c. topology on $E / G$, we denote by $\gamma:=\tau \vee \alpha$ the weakest l.c. topology on $E$ such that $\tau \leq \gamma, \gamma / G=\alpha, \gamma|G=\tau| G$, cf. e.g. [1]. The sets $U \cap q^{-1}(V)$ compose a basis of neighbourhoods of zero for $\gamma$, where $U, V$ run over bases of neighbourhoods of zero for $\tau$ and $\alpha$, respectively, $q:=E E / G$ is the quotient map. By $\sup \{\tau, \alpha\}$ we denote the weakest l.c. topology on $E$ which is finer than $\tau$ and $\alpha$.

By the Mackey topology $\mu\left(E, E^{*}\right)$ associated with a lcs $E=(E, \tau)$ we mean the finest locally convex topology on $E$ compatible with $\tau$. In [14] Van Tiel showed that every lcs over spherically complete $K$ admits the Mackey topology.

In [3] Ingleton obtained a non-archimedean variant of the Hahn-Banach theorem for normed spaces, where $K$ is spherically complete.

Theorem 2 If $E=(E,\|\cdot\|)$ is a normed space over $K$ and $K$ is spherically complete and $D$ is a subspace of $E$, then for every continuous linear functional $g \in D^{*}$ there exists a continuous linear extension $f \in E^{*}$ of $g$ such that $\|g\|=\|f\|$.

This suggests the following : A lcs $E$ will be said to have the Hahn-Banach Extension Property (HBEP) [9] if for every subspace $D$ every $g \in D^{*}$ can be extended to $f \in E^{*}$. It is known that every lcs over spherically complete $K$ has the HBEP, cf. e.g. [11].

The following theorem characterizes the spherical completeness of $K$ in terms of classical theorems of Functional Analysis; cf. also [5], [6] and [12], Theorem 4.15. The proof of our Theorem 3 uses some ideas of [4] extended to the non-archimedean case.
$l^{\infty}$ (resp. $c_{0}$ ) denotes the space of the bounded sequences (resp. the sequences of limit 0 ) with coefficients in $K$.

Theorem 3 The following conditions on $K$ are equivalent:
(i) $K$ is spherically complete.
(ii) There exists $g \in\left(l^{\infty}\right)^{*}$ such that $g(x)=\sum_{n} x_{n}$ for every $x \in c_{0}$.
(iii) $\left(l^{\infty} / c_{0}\right)^{*} \neq 0$.
(iv) Every lcs over $K$ admits the Mackey topology.
(v) Every lcs over $K$ (resp. K-normed space) has the HBEP.
(vi) The completion of a dual-separating lcs over $K$ (resp. K-normed space) is dualseparating.
(vii) Every closed subspace of a dual-separating lcs over $K$ (resp. $K$-normed space) is weakly closed.
(viii) For every lcs over $K$ (resp. K-normed space) every weakly convergent sequence is convergent.
(ix) Every weak Schauder basis in a lcs over K (resp. K-normed space) is a Schauder basis.
Proof By Theorem 4.15 of [12] conditions (i), (ii), (iii) are equivalent. (i) implies (iv) : [14], Theorem 4.17. (i) implies (v) : [3], [11]. The implications (v) implies (vi), (v) implies (vii) are obvious. (i) implies (viii) : see [7]; Theorem 3, [2], Proposition 4.3. (viii) implies (ix) is obvious.
(iv) implies (i): Assume that $K$ is not spherically complete and consider the space $l^{\infty}$ of $K$-valued bounded sequences endowed with the topology $\tau$ generated by the norm $\|x\|=\sup _{n}\left|x_{n}\right|, x=\left(x_{n}\right) \in l^{\infty}$. Let $f$ be a non-zero linear function on $l^{\infty}$ with $\left.f\right|_{c_{0}}=0$. Set $E:=l^{\infty}$ and $F:=c_{0}$. Define a linear functional $h$ on the quotient space $E / F$ by $h(q(x))=f(x)$, where $q: E \rightarrow E / F$ is the quotient map. Let $\alpha$ be the quotient topology
of $E / F$. Since $(E / F, \alpha)^{*}=0$, see (iii) implies (i), $F$ is dense in the weak topology $\sigma\left(E, E^{*}\right)$ (recall that $E^{*}=F,[12]$, Theorem 4.17). Observe that on $E / F$ there exists a $K$-normed topology $\beta$ such that $(E / F, \alpha)$ and $(E / F, \beta)$ are isomorphic and $h$ is continuous in the topology $\sup \{\alpha, \beta\}$. Indeed, choose $x_{0} \in E / F$ such that $h\left(x_{0}\right)=2$ and define a linear map $T: E / F \rightarrow E / F$ by $T(x):=x-h(x) x_{0}, x \in E / F$. Then $T^{2}=i d$. Define $\beta:=T(\alpha)$ (the image topology). Then $h$ is continuous in the topology $\sup \{\alpha, \beta\}$.

Set $\gamma_{\alpha}:=\sigma\left(E, E^{*}\right) \vee \alpha, \quad \gamma_{\beta}:=\sigma\left(E, E^{*}\right) \vee \beta$. Then $\gamma_{\alpha}$ and $\gamma_{\beta}$ are compatible with $\sigma\left(E, E^{*}\right)$, hence with $\tau$. Assume that $E$ admits the finest locally convex topology $\mu$ compatible with $\tau$. Then $\sigma\left(E, E^{*}\right) \leq \sup \left\{\gamma_{\alpha}, \gamma_{\beta}\right\} \leq \mu$.

On the other hand $\sup \left\{\gamma_{\alpha}, \gamma_{\beta}\right\} / F=\sup \{\alpha, \beta\}$. Therefore $f$ is continuous in $\sup \left\{\gamma_{\alpha}, \gamma_{\beta}\right\}$. Since $f$ is not continuous in $\sigma\left(E, E^{*}\right)$ we get a contradiction. The proof is complete.
(vi) implies (i) : Assume that $K$ is not spherically complete. By the Baire category theorem we find a dense subspace $G$ of $E$ with $\operatorname{dim}(E / G)=\operatorname{dim}(E / F)$, where $E$ and $F$ are defined as above. Indeed, let $\left\{x_{s}\right\}_{s \in S}$ be a Hamel basis of $E$ and $\left(S_{n}\right)$ a partition of $S$ such that $S=\bigcup_{n \in \mathbb{N}} S_{n}$ and $\operatorname{card} S_{n}=\operatorname{card} S, n \in \mathbb{N}$.

For every $n \in \mathbb{N}$, we denote by $G_{n}$ the vector space generated by the elements $x_{s}$ when $s$ runs in $\bigcup_{k=1}^{n} S_{k}$. Then we have $E=\bigcup_{n \in \mathbb{N}} G_{n}$ and $\operatorname{dim} G_{n}=\operatorname{dim}\left(E / G_{n}\right)=\operatorname{dim} E, n \in \mathbb{N}$. Then there exists $m \in \mathbb{N}$ such that $G_{m}$ is dense in $E$. Hence we obtain a subspace $G$ as required. Let $\alpha$ be a $K$-normed topology on $E / G$ such that the spaces $(E / G, \alpha)$ and $(E / F, \tau / F)$ are isomorphic. Then the topology $\gamma:=\tau \vee \alpha$ is compatible with $\tau$ and strictly finer than $\tau$. Let $E_{0}$ be the completion of the dual-separating $K$-normed space $(E, \gamma)$. Choose $x \in E_{0} \backslash E$. There exists a sequence $\left(x_{n}\right)$ in $E$ and $y \in E$ such that $x_{n} \rightarrow x$ in $E_{0}$ and $x_{n} \rightarrow y$ in $(E, \tau)$. Then $f(x-y)=0$ for all $f \in E_{o}^{*}$ but $x-y \neq 0$. This completes the proof.
(vii) implies (i): Assume that $K$ is not spherically complete. The space $G$ constructed in the previous case is closed in $(E, \gamma)$ and dense in $\left(E, \sigma\left(E, E^{*}\right)\right)$, where $E^{*}:=(E, \gamma)^{*}$.
(v) implies (i): Assume that $K$ is not spherically complete. Let $\left(e_{n}\right)$ be the sequence of the unit vectors in $E$, where $E$ is as above. Then $e_{n} \rightarrow 0$ in $\sigma\left(E, E^{*}\right)$, [13]. Clearly $\left(e_{n}\right)$ is a normalized Schauder basis in $F$. If $x=\left(x_{n}\right) \in F$, then $x=\sum_{n} x_{n} e_{n}$. Set $g(x):=\sum_{n} x_{n}$. Then $g$ is a well-defined continuous linear functional on $F$. Suppose that $g$ has a continuous linear extension $f$ to the whole space $E$. Then $f\left(e_{n}\right) \rightarrow 0$ but $g\left(e_{n}\right)=1$ for all $n \in \mathbb{N}$, a contradiction.
(viii) implies (i): See the proof of the previous implication.
(ix) implies (i): Assume that $K$ is not spherically complete. The sequence $\left(e_{n}\right)$ is a Schauder basis in $\left(E, \sigma\left(E, E^{*}\right)\right)$ but it is not a Schauder basis in the original topology of $E$. The second part of this sentence follows from the fact that $E$ is not of countable type, cf. e.g. [12]. On the other hand, by Theorem 4.17 of [12] (and its proof) the space $E$ is reflexive and for every $g \in E^{*}$ there exists $\left(a_{n}\right) \in F$ such that $g(x)=\sum_{n} x_{n} a_{n}$ for every
$x=\left(x_{n}\right) \in E$. Since $\left(E, \sigma\left(E, E^{*}\right)\right)$ is a sequentially complete lcs [12], Theorem 9.6, then $\sum_{k=1}^{n} x_{k} e_{k}$ weakly converges to $x=\left(x_{n}\right)$.

Remark In [9] Martinez-Maurica and Perez-Garcia proved that whenever $K$ is spherically complete, then the local convexity is a three space property, i.e. if $E$ is an A-Banach tvs over $K$ and $F$ its subspace such that $F$ and $E / F$ are locally convex, then $E$ is locally convex. Is the converse also true?

By $L(E, F)$ we denote the space of all continuous linear maps between lcs $E$ and $F$. A topology $\alpha$ on $E$ will be called compatible with the pair $(E, L(E, F))$ if $L((E, \alpha), F)=$ $L(E, F)$; if $F=$, as usual we shall say that $\alpha$ is compatible with the dual pair $\left(E, E^{*}\right)$, where $E^{*}:=L(E, K)$.

A lcs space $F$ will be said to have the Mackey-Arens property (MA-property) if for every lcs space $E$ the finest topology $\mu(E, L(E, F)$ ) compatible with ( $E, L(E, F)$ ) exists, [7].

As we have already mentioned Van Tiel [14] proved that if $K$ is spherically complete, then $K$ has the MA-property, i.e. every $K$-space $E$ over spherically complete $K$ admits the finest topology $\mu\left(E, E^{*}\right)$ compatible with the dual pair $\left(E, E^{*}\right)$. We have already proved the converse : If $K$ is not spherically complete, then $\ell^{\infty}$ does not admit the Mackey topology $\mu\left(\ell^{\infty},\left(\ell^{\infty}\right)^{*}\right)$. Hence
Corollary $K$ is spherically complete iff it has the MA-property.
On the other hand one has the following
Theorem 4 Every spherically complete normed $K$-space $F=(F,\|\|$.$) has the MA-$ property.

We shall need the following
Lemma 1 Let $E, F$ be two vector spaces over $K$, where $F$ is endowed with a norm $\|\cdot\|$ and $p, q$ are seminorms on $E$. Let $T: E \rightarrow F$ be a linear map such that $\|(T(x))\| \leq$ $\max (p(x), q(x))$. If $F$ is spherically complete, then there exists two linear maps $T_{i}: E \rightarrow F$, $i=1,2$, such that $T=T_{1}+T_{2}$ and $\left\|\left(T_{1}(x)\right)\right\| \leq p(x),\left\|\left(T_{2}(x)\right)\right\| \leq q(x), x \in E$.
Proof Set $P(x, x)=T(x), U(x, y)=\max \{p(x), q(y)\}, x, y \in E$. Then $U(x, y)$ is a seminorm on $E \times E$ and $\|(P(x, x))\|=\|(T(x))\| \leq \max \{p(x), q(x)\}=U(x, x)$. Since $F$ is spherically complete, then by Ingleton theorem, cf. e.g. [6], Theorem 4.18, there exists a linear map $P_{0}: E \times E \rightarrow F$ extending $P$ such that $\left\|\left(P_{0}(x, y)\right)\right\| \leq U(x, y), x, y \in E$. To complete the proof it is enough to put $T_{1}(x)=P_{0}(x, 0), T_{2}(x)=P_{0}(0, x)$.

We shall also need the following lemma. Its proof uses some ideas of [1] and [4].
Lemma 2 Let $E, F$ be two dual-separating $K$-spaces over non-spherically complete $K$ and such that $F$ is complete and $E$ is an infinite dimensional metrizable and complete. Then $E$ admits two topologies $\tau_{1}$ and $\tau_{2}$ strictly finer than the original one of $E$ and compatible with the pair $(E, L(E, F))$ and such that the topology sup $\left\{\tau_{1}, \tau_{2}\right\}$ is not compatible with $(E, L(E, F))$.

Proof : Observe that $E$ contains a dense subspace $G$ with $\operatorname{dim}(E / G)=\operatorname{dim}\left(l^{\infty} / c_{0}\right)$. Let $h$ be a non-zero linear functional on $E$ vanishing on $G$. As above we construct on $E$ two topologies $\tau_{1}$ and $\tau_{2}$ strictly finer than the original one $\tau$ of $E$ such that $\tau_{j}|G=\tau| G$ and $\left(E / G, \tau_{j} / G\right)$ is isomorphic to the quotient space $l^{\infty} / c_{0}, j=1,2$, and $h$ is continuous in $\sup \left\{\tau_{1}, \tau_{2}\right\}$. We show that the topologies $\tau_{j}, j=1,2$, are compatible with the pair $(E, L(E, F))$. Fix $j \in\{1,2\}$ and non-zero $T \in L\left(\left(E, \tau_{j}\right), F\right)$. There exists $x_{0} \in E$ and $f \in F^{*}$ such that $f\left(T\left(x_{0}\right)\right) \neq 0$. Suppose that $T \mid G=\{0\}$. Then the map $\left.q(x) \rightarrow f(T x)\right)$ defines a non-zero continuous linear functional on $\left(E / G, \tau_{j} / G\right), q: E \rightarrow E / G$ is the quotient map. Since $\left(l^{\infty} / c_{0}\right)^{*}=\{0\}$, [12], Corollary 4.3, we get a contradiction. Hence $T \mid G$ is non-zero. Since $G$ is dense in $E$ and $\tau$ and $\tau_{j}$ coincide on $G$, there exists a continuous linear extension $W$ of $T$ to $E$. It is easy to see that $T=W$. Hence $T \in L(E, F)$. Finally the map $x \rightarrow h(x) y$, for fixed $y \in F$, defines a $\tau$-discontinuous linear map $H$ of $E$ into $F$ such that $H \in L\left(\left(E, \sup \tau_{1}, \tau_{2}\right), F\right)$.

Proof of Theorem 4 Let $E=(E, \tau)$ be a lcs and $\mathcal{F}$ the family of all topologies on $E$ compatible with $(E, L(E, F))$. It is enough to show that the topology $\mu:=\sup \mathcal{F}$ belongs to $\mathcal{F}$. Let $T:(E, \mu) \rightarrow F$ be a continuous linear map. There exist seminorms $p_{j}$ on $E, j=1, \ldots, n$, continuous in topologies $\gamma_{j}\left(\gamma_{j} \in \mathcal{F}\right)$, respectively, and $M>0$ such that $\mid(T x) \| \leq M \max _{1 \leq j \leq n} p_{j}(x)$ for every $x \in E$. Using Lemma 1 one shows that $T$ is $\tau$-continuous.

Remarks (1) There exist complete normed $K$-spaces having the MA-property which are not spherically complete. In fact, assume that $K$ is spherically complete; then $\ell^{\infty}$ is spherically complete [12], p. 97; hence $\ell^{\infty}$ has the MA-property (by our Theorem 4). On the other hand there exists on the space $\ell^{\infty}$ another norm $\nu$ which is equivalent with the usual norm, such that ( $\ell^{\infty}, \nu$ ) is not spherically complete [12], p. 50 and p. 98 . On the other hand the space $\left(\ell^{\infty}, \nu\right)$ has the MA-property.
(2) Let $E$ be an infinite dimensional normed and complete $K$-space. Since $F:=$ $\prod_{n} E_{n} / \bigoplus_{n} E_{n}$, where $E_{n}=E$ for every $n \in \mathbb{N}$, is spherically complete for any $K$ [12], Theorem 4.1, then by our Theorem 4 the space $F$ has the MA-property. For concrete spaces put $E=\ell^{\infty}$; then $F=\ell^{\infty} / c_{0}$. If $K$ is not spherically complete, then by Lemma 2 the space $\ell^{\infty}$ does not admit the Mackey topology $\mu\left(\ell^{\infty},\left(\ell^{\infty}\right)^{*}\right)$ but $\ell^{\infty} / c_{0}$ has the MA-property. In particular there exists on $\ell^{\infty}$ the finest topology $\mu$ compatible with ( $\ell^{\infty}, L\left(\ell^{\infty}, \ell^{\infty} / c_{0}\right)$ ).
(3) Let $E$ and $F$ be $K$-spaces and assume that $E$ admits the Mackey topology $\mu=$ $\mu\left(E, E^{*}\right)$. Then the finest topology on $E$ compatible with $((E, \mu), L((E, \mu), F))$ exists and equals $\mu$.
(4) In [13], Corollary 7.9, Schikhof proved that for polarly barrelled or polarly bornological $K$-spaces $(E, \tau)$ where $K$ is not spherically complete, the finest polar topology $\mu\left(E, E^{*}\right)$ compatible with ( $E, E^{*}$ ) exists and equals $\tau$.
