THE CONJECTURES OF BIRCH AND SWINNERTON-DYER AND THE CLASS NUMBERS OF QUADRATIC FIELDS
by

Dorian M. GOLDFELD

## 1. The Class Number Problem

Let $X$ be a real, primitive, Dirichlet character (mod d) . Associated to $x$ we have a quadratic field

$$
K=Q(\sqrt{X(-1) d})
$$

which is real or imaginary according as $x(-1)=+1$ or -1 . If we let

$$
H=\left\{\begin{array}{ll}
h & \text { if } x(-1)=-1 \\
h . \log & \varepsilon_{0}
\end{array} \quad \text { if } x(-1)=+1 ~ \$\right.
$$

where $h$ is the class number and $\varepsilon_{0}$ is the fundamental unit of $K$, then C.L. Siegel [4], [10] has proved the important result

$$
H>c(\varepsilon) d^{\frac{1}{2}-\varepsilon}
$$

where for all $\varepsilon>0, c(\varepsilon)>0$ is an ineffectively computable constant.
Actually, one expects even more to be true, since if $H=O(\sqrt{\alpha} / \log d)$,
there exists a real number $\beta$ satisfying (see [5], [7])

$$
\left.1-\beta \sim \frac{6}{\pi^{2}} L(1, x) \sum_{\substack{a, b, c \\-a<b \leq a<\frac{1}{4} \sqrt{d} \\ b^{2}-4 a c=x(-1) d}} a^{-1}\right)^{-1}
$$

for which

$$
L(\beta, \chi)=0
$$

This, of course, contradicts the Riemann Hypothesis, and it is, therefore, likely that $H$. log $d / \sqrt{d}$ never gets too small.

The strongest known effective lower bounds for $H$ have been obtained by Stark [11] and Baker [1], who established that there are only 9 imaginary quadratic fields with class number one, and that there are exactly 18 imaginary quadratic fields with class number two. As a consequence, the lower bound

$$
H \geqq 3 \quad(d>427, x(-1)=-1)
$$

was obtained. The general Gauss problem of effectively determining how many imaginary quadratic fields have a given class number $h>2$ still remains open.
S. Chowla has raised an analogous problem for real quadratic fields. If $d$ is of the form $d=m^{2}+1$ so that the fundamental unit is minimal, Chowla has conjectured that there will be only finitely many real quadratic fields of this type with a given class number, and that these fields can be effectively determined.

## 2. The Birch-Swinnerton-Dyer Conjectures

Let $E$ be an elliptic curve over $Q$, with conductor $N$ (see [13]). If $p$ does not divide $N$, the reduction of $E$ modulo $p$ is an elliptic curve over $\mathrm{Z} / \mathrm{pZ}$; let $\mathrm{N}_{\mathrm{p}}$ be its number of points, and put $t_{p}=p+1-N_{p}$. The HasseWeil I-function of E is defined to be :

$$
I_{E}(s)=\prod_{p \mid N}\left(1-a_{p} p^{-s}\right)^{-1} \prod_{\rho / K_{N}}\left(1-t_{p} p^{-s}+p^{1-2 s}\right)^{-1}=\sum E_{n} n^{-s}
$$

where the $a_{p}, s$ (for $p \mid N$ ) are equal to 0,1 or -1 (cf. [13]).
Weil (loc. cit.) has conjectured that $I_{E}(s)$ is entire and satisfies the functional equation

$$
(\sqrt{N} / 2 \pi)^{s} \Gamma(s) I_{E}(s)= \pm(\sqrt{N} / 2 \pi)^{2-s} \Gamma(2-s) I_{E}(2-s)
$$

and that

$$
\sum E_{n} e^{2 \pi i n z}
$$

is a cusp form of weight 2 for the congruence subgroup $\Gamma_{0}(N)$.
Let $E(Q)$ denote the group of rational points on $E$. Then if $E(Q)$ has $g$ independent generators of infinite order, Birch and Swinnerton-Dyer have conjectured [2]

CONJECTURE $L_{E}(s)$ has a zero of order $g$ at $s=1$.
This conjecture may prove useful in the class number problem (for both real and imaginary fields), for we can show [6]

THEOREM 1 - If $I_{E}(s)$ satisfies Weil's conjecture and $I_{E}(s)$ has a zero of order $g$ at $s=1$, then for $(d, N)=1$

$$
H>\frac{c_{2}}{g^{4 g_{N} 13}}(\log d)^{g^{-u-1}} \exp \left(-21 g^{\frac{1}{2}}(\log \log d)^{\frac{1}{2}}\right) \quad, \quad\left(d>e^{e^{c_{1} N g^{3}}}\right)
$$

where $u=1,2$ is suitably chosen so that

$$
x(-N)=(-1)^{g-u}
$$

and the constants $c_{1}, c_{2}>0$ can be effectively computed and are independent of $\mathrm{g}, \mathrm{N}$, and d .

If we simply take $u=2$ in the above Theorem, then the condition $(d, N)=1$ can be dispensed with. In this case, however, the proof of Theorem (1) will have to be slightly modified to take into account a finite number of bad primes dividing ( $\mathrm{d}, \mathrm{N}$ ) .
3. Example 1

Stephens [12] has shown that the elliptic curve

$$
E_{1}: y^{2}=x^{3}-2^{4} \cdot 3^{7} \cdot 73^{2}
$$

satisfies

$$
\begin{gathered}
g=\text { rank of } E_{1}(Q)=3, \quad N=3^{3} \cdot 73^{2} \\
(\sqrt{N} / 2 \pi)^{s} \Gamma(s) I_{E_{1}}(s)=-(\sqrt{N} / 2 \pi)^{2-s} \Gamma(2-s) I_{E_{1}}(2-s) \quad .
\end{gathered}
$$

$\mathrm{L}_{\mathrm{E}_{1}}(\mathrm{~s})$ satisfies Weil's conjecture since $\mathrm{E}_{1}$ has complex multiplication by $\sqrt{-3}$ so that by a Theorem of Deuring [3] $\mathrm{L}_{\mathrm{E}_{1}}(\mathrm{~s})$ is a Hecke I-series with Grössencharakter of $Q(\sqrt{-3})$. Moreover, since the functional equation has the - sign, $\mathrm{I}_{\mathrm{E}_{1}}$ (s) must have a zero of odd order at $\mathrm{s}=1$. It immediately follows that

$$
I_{\mathrm{E}_{1}}(1)=0
$$

As a consequence of Theorem (1), we have

THEOREM $2-$ If $L^{\prime} E_{1}(1)=0$, then for every $\varepsilon>0$ there exists $c(\varepsilon)>0$ such that

$$
H>c(\varepsilon)(\log d)^{1-\varepsilon}, \quad(d, 3.73)=1
$$

in the case $X(-1)=-1, X(3)=-1$ - The constant $c(\varepsilon)$ can be effectively computed and is independent of $d$.

## 4. Example 2

Consider the curve

$$
E_{2}: y^{2}=x^{3}+(3 \cdot 7 \cdot 11 \cdot 17 \cdot 41)^{2} x
$$

found by Wiman [14]. For this example

$$
\begin{aligned}
& g=\operatorname{rank} \text { of } \mathrm{E}_{2}(Q)=4, \quad N=2^{6}(3.7 .11 .17 .41)^{2} \\
& (\sqrt{N} / 2 \pi)^{s} \Gamma(s) I_{\mathrm{E}_{2}}(\mathrm{~s})=+(\sqrt{N} / 2 \pi)^{2-s} \Gamma(2-s) I_{\mathrm{E}_{2}}(2-s)
\end{aligned}
$$

Since $\mathrm{E}_{2}$ has complex multiplication by $\sqrt{-1}$, Weil's conjecture is again satisfied. The $+\operatorname{sign}$ in the functional equation shows that $\mathrm{I}_{\mathrm{E}_{2}}$ (s) has a zero of even
order at $s=1$. Since $\mathrm{I}_{\mathrm{E}_{2}}(1)$ must be an integral multiple of a predictable number, one can show by computer computation that

$$
\mathrm{L}_{\mathrm{E}_{2}}(1)=0 \quad, \quad \mathrm{~L}_{\mathrm{E}_{2}^{\prime}}(1)=0
$$

THEOREM 3- If $L_{E_{2}}(1)=0$, then for every $\varepsilon>0$, there exists $c(\varepsilon)>0$ such that

$$
H>c(\varepsilon)(\log d)^{2-\epsilon}, \quad(d, 2 \cdot 3 \cdot 7 \cdot 11 \cdot 17 \cdot 41)=1
$$

and

$$
H>c(\varepsilon)(\log d)^{1-\varepsilon} \quad \text { (no condition on } d \text { ) }
$$

in the case $x(-1)=1$. The constant $c(\varepsilon)$ can be effectively computed and is independent of d .

It immediately follows that the vanishing of $L_{E_{2}}(1)$ would allow one to effectively determine all imaginary quadratic fields having a given class number, and, therefore, provide a solution to the class number problem. Unfortunately, the curves $E_{1}$ and $E_{2}$ provide no information in the case of real quadratic fields. To get a solution to Chowla's conjecture, for example, one would require an elliptic curve $E$ for which $I_{E}(s)$ has a zero of order 5 at $s=1$.

## 5. Some Generalizations

Theorem (1) can be generalized to a rather wide class of I-functions associated to modular forms of arithmetic type. If

$$
L_{1}(s)=\prod_{p} \prod_{i=1}^{k}\left(1-\alpha_{p, i} p^{-s}\right)^{-1}, \quad\left|\alpha_{p, i}\right| \leqq 1
$$

is such an I-function satisfying a functional equation of type

$$
M^{s} T(s) L_{1}(s)=w M^{1-s^{s}} T(1-s) L_{1}(1-s) \quad, \quad|w|=1
$$

where $M$ is a positive real number and $T(s)$ is some finite product of $\Gamma$-functions $\left(T(s)=\prod \Gamma\left(s+a_{i}\right)\right)$, and if the twisted series

$$
L_{1}(s, x)=\prod_{p} \prod_{i=1}^{k}\left(1-x(p) \alpha_{p, i} p^{-s}\right)^{-1}
$$

satisfies

$$
M_{X}^{S_{T} T_{X}}(s) I_{1}(s, X)=W_{\chi} M_{X}^{1-s_{T}} T_{X}(1-s) L_{1}(1-s, x) \quad, \quad\left|W_{X}\right|=1
$$ where $T_{X}(s)$ is again some finite product of $\Gamma$-functions and (*)

$$
M_{X} \ll d M
$$

one can in general show that for every $\varepsilon>0$, there exists an effectively computable constant $c(\varepsilon)>0$ such that

$$
\begin{equation*}
H>c(\varepsilon)(\log d)^{g-u-p-\varepsilon} . \tag{**}
\end{equation*}
$$

Here, $g$ is the order of the zero of $L_{1}(s)$ at $s=\frac{1}{2} ; u=1$ or 2 according as

$$
1+(-1)^{g-1}{ }_{w w_{x}} \neq 0 \text { or }=0
$$

and $\rho$ is the order of the zero of

$$
L_{2}(s)=\prod_{p} \prod_{i=1}^{k}\left(1-\alpha_{p, i}^{2} p^{-s}\right)^{-1}
$$

at $s=1$. The condition (*) seems to force $k \leqq 2$.
If $L_{1}(s)$ is an L-function associated to an elliptic curve, one can show by Rankin's method [9] that $\rho=1$, and this is the main reason why zeros of order $\geqq 3$ are needed to get non-trivial lower bounds for $H$. It would be of considerable interest to find examples of I-functions for which $g-\rho \geqq 2$ and $\rho<1$ -

The proof of these results is based on the general principle that if $H$ is too small then $X(n)$ behaves like Liouville's function $\lambda(n)$

$$
\text { (where } \left.\zeta(2 s) / \zeta(s)=\sum \lambda(n) n^{-s}\right)
$$

for $n \ll d$. This can easily be seen in the case of an imaginary quadratic field
with class number one. If the field has discriminant -d , then for a prime $p<d, x(p)=+1$ if and only if we have the representation

$$
p=x^{2}+x y+\frac{(d+1)}{4} y^{2}
$$

from which it follows that $X(p)=-1$ for all $p<(d+1) / 4$. This implies that $x(n)=\lambda(n)$ for $n<(d+1) / 4$.

If one writes

$$
L_{1}(s) I_{1}(s, x)=G(s) L_{2}(2 s),
$$

then $G(s)$ measures the deviation by which $X(n)$ differs from Liouville's function $\lambda(n)$. We show that this deviation can be measured in terms of $H$. Let

$$
G(s)=\sum g_{n} n^{-s}, \quad G(s, x)=\sum_{n<x} g_{n} n^{-s} .
$$

It is not hard to see that $G(s)$ is majorized by

$$
F(s)=(\zeta(s) L(s, x) / \zeta(2 s))^{k},
$$

that is to say $\left|g_{n}\right|$ is bounded by the $n^{\text {th }}$ coefficient in the Dirichlet series expansion for $F(s)$. By expanding $F(s)$ into a rapidly converging series of Bessel functions it is possible to estimate $G\left(\frac{1}{2}, d\right)$ in terms of $L(1, x)$.

On using a general method of A.F. Lavrik [8] one can expand

$$
M^{s} M_{X}^{s} \mathbf{s}^{T}(s) T_{\chi}(s) L_{1}(s) L_{1}(s, \chi)
$$

into a rapidly converging series of incomplete $\Gamma$-functions whose main contribution comes from the terms $n \ll M_{x}$, and in this way it can be proved that

$$
\begin{aligned}
& \left(\frac{d}{d s}\right)^{g-1}\left[\left(\mathbb{M M}_{\chi}\right)^{s_{T}(s) T_{X}}(s) L_{1}(s) L_{1}(s, x)\right]{ }_{s=\frac{d}{d}}= \\
& =\delta\left(\frac{d}{d s}\right)^{g-1}\left[\left(\operatorname{MM}_{X}\right)^{s} T(s) T_{X}(s) G(s, U) L_{2}(2 s)\right]_{s=\frac{1}{2}}+O\left(\operatorname{MM}_{X} L(1, X)(\log d)^{\varepsilon}\right) \quad .
\end{aligned}
$$

where

$$
\delta=1+(-1)^{g-1} w_{x}
$$

and $U$ is a power of log $d$. Since $L_{1}(s)$ has a zero of order $g$ at $s=\frac{1}{2}$ and $G\left(\frac{1}{2}, U\right)$ can be bounded from below if $H$ is sufficiently small it follows that one can obtain results of type ( ${ }^{*}$ ) . Note that there will be a loss of $\rho$ powers of log d if $L_{2}(s)$ has a zero of order $\rho$ at $s=1$, and a loss of one $\log d$ if $\delta=0$.
