## SOML: DYNAMICS OF PSEUDO-ANOSOV DIFFEOMORPHISMS

by A. FATHI and M. SHUB

§ I. - Topological entropy
§ II. - The fundamental group
§ III. - Subshifts of finite type
§ IV. - The entropy of pseudo-Anosov diffeomorphisms
§ V. - Construction of Markov partitions for pseudo-Anosov diffeomorphisms
§ VI. - Pseudo-Anosov diffeomorphisms are Bernoulli.

We prove in this "exposé" that a pseudo-Anosov diffeomorphism realizes the minimum of topological entropy in its isotopy class. In section I , we define topological entropy and give its elementary properties. In section II, we define the growth of an endomorphism of a group and show that the topological entropy of a map is greater than the growth of the endomorphism it induces on the fundamental group. In section III, we define subshifts of finite type and give some of their properties. In section IV, we prove that the topological entropy of a pseudo-Anosov diffeomorphism is the growth rate of the automorphism induced on the fundamental group, it is also $\log \lambda$, where $\lambda>1$ is the stretching factor of f on the unstable foliation. In section V , we prove the existence of a Markov partition for a pseudo-Anosov diffeomorphism, this fact is used in section IV. In section VI, we show that a pseudo-Anosov map is Bernoulli.

## § I. - TOPOLOGICAL ENTROPY

Topological entropy was defined to be a generalization of measure theoretic entropy [1] . In some sense, entropy is a number (possibly infinite) which describes "how much" dynamics a map has. Here the emphasis, of course, must be on asymptotic behaviour. For example, if $f: X \rightarrow X$ is a map and $N_{n}(f)$ is the cardinality of the fixed point set of $f^{n}$, then $\lim \sup \frac{1}{n} \log N_{n}(f)$ is one measure of "how much" dynamics $f$ has ; but, if we consider $f \times R_{\theta}: X \times T^{1} \rightarrow X \times T^{1}$ to be $\left(f \times R_{\theta}\right)(x, \alpha)=$ $(f(x), \theta+\alpha)$ where $T^{1}=\mathbb{R} / \mathbb{Z}$ and $\theta$ is irrational, then $N_{n}\left(f \times R_{\theta}\right)=0$, and yet $f \times R_{\theta}$ should have at least as "much" dynamics as $f$. Topological entropy is a topological invariant which overcomes this difficulty.

We describe a lot of material frequently without crediting authors.

Definitions. Let $\mathrm{f}: \mathrm{X} \rightarrow \mathrm{X}$ be a continuous map of a compact topological space X . Let $a=\left\{A_{i}\right\}_{i \in I}$ and $\mathscr{C}=\left\{B_{j}\right\}_{j \in J}$ be open covers of $X$, the open cover $\left\{A_{i} \cap B_{j}\right\}_{i \in I}$ will be denoted by $G v \in$. If $a$ is a cover, $N_{n}(f, a)$ denotes the $j \in J$
minimum cardinality of a subcover of $G v f^{-1} G \vee \ldots v f^{-n+1} G$, and $h(f, a)=$ $=\lim \sup \frac{1}{n} \log N_{n}(f, a)$. The topological entropy of $f$ is $h(f)=\sup _{G} h(f, a)$ where the supremum is taken over all open covers of X .

Proposition. Let X and Y be compact spaces. Let $\mathrm{f}: \mathrm{X} \rightarrow \mathrm{X}, \mathrm{g}: \mathrm{Y} \rightarrow \mathrm{Y}$ and $h: X \rightarrow Y$ be continuous. Suppose that $h$ is surjective and $h f=g h:$

then, $h(f) \geq h(g)$.
In particular, if $h$ is a homeomorphism, $h(f)=h(g)$. So topological entropy is a topological invariant.

Proof. Pull back the open covers of $Y$ to open covers of $X$.

For metric spaces, compact or not, Bowen has proposed the following definition. Suppose $\mathrm{f}: \mathrm{X} \rightarrow \mathrm{X}$ is a continuous map of a metric space X and suppose
$K \subset X$ is compact. Let $\varepsilon$ be $>0$. We say that a set $E \subset K$ is ( $n, \varepsilon$ )-separated if, given $x, y \in E$ with $x \neq y$, there is $0 \leq i<n$ such that $d\left(f^{i}(x), f^{i}(y)\right) \geq \varepsilon$. We let $S_{K}(n, \varepsilon)$ be the maximal cardinality of an $(n, \varepsilon)$-separated set contained in $K$. We say that the set $E$ is ( $n, \varepsilon$ )-spanning for $K$ if, given $y \in K$, there is an $x \in E$ such that $d\left(f^{i}(x), f^{i}(y)\right)<\varepsilon$ for each $i$ with $0 \leq i<n$. We let $r_{K}(n, \varepsilon)$ be the minimal cardinality of an ( $\mathrm{n}, \varepsilon$ )-spanning set contained in K. It is easy to see that $r_{K}(n, \varepsilon) \leq s_{K}(n, \epsilon) \leq r_{K}\left(n, \frac{\varepsilon}{2}\right)$. We let $\bar{s}_{K}(\varepsilon)=\lim \sup \frac{1}{n} \log s_{K}(n, \varepsilon)$ and $\bar{r}_{\mathrm{K}}(\varepsilon)=\lim \sup \frac{1}{\mathrm{n}} \log \mathrm{r}_{\mathrm{K}}(\mathrm{n}, \varepsilon)$. Obviously, $\overline{\mathrm{s}}_{\mathrm{K}}(\epsilon)$ and $\overline{\mathrm{r}}_{\mathrm{K}}(\varepsilon)$ are decreasing functions of $\varepsilon$, and $\bar{r}_{K}(\varepsilon) \leq \bar{s}_{K}(\varepsilon) \leq \bar{r}_{K}\left(\frac{\varepsilon}{2}\right)$. Hence, we may define $h_{K}(f)=\lim _{\varepsilon \rightarrow 0} \bar{s}_{K}(\varepsilon)=$ $=\lim _{\varepsilon \rightarrow 0} \overline{\mathrm{r}}_{\mathrm{K}}(\varepsilon)$. Finally, we put $\mathrm{h}_{\mathrm{X}}(\mathrm{f})=\sup \left\{\mathrm{h}_{\mathrm{K}}(\mathrm{f}) \mid \mathrm{K}\right.$ compact $\left.\subset \mathrm{X}\right\}$.

Proposition [2], [4]. If $X$ is a compact metric space and $f: X \rightarrow X$ is continuous, then $h_{X}(f)=h(f)$.

The proof is rather straightforward. By the Lebesgue covering lemma, every open cover has a refinement which consists of $\varepsilon$-balls.

The number $h_{X}(f)$ depends on the metric on $X$ and makes best sense for uniformly continuous maps.

Suppose that $X$ and $Y$ are metric spaces, we say that $p: X \rightarrow Y$ is a metric covering map if it is surjective and satisfies the following condition : there exists $\varepsilon>0$ such that, for any $0<\delta<\varepsilon$, any $y \in Y$ and any $x \in p^{-1}(y)$, the map $p: B_{\delta}(x) \rightarrow B_{\delta}(y)$ is a bifective isometry (here $B_{\delta}(\cdot)$ is the $\delta$-ball).

The main example we have in mind is the universal covering $p: \widetilde{M} \rightarrow M$ of a compact differentiable manifold M .

Proposition. Suppose $p: X \rightarrow Y$ is a metric covering and $f: X \rightarrow X, g: Y \rightarrow Y$ are uniformly continuous. If $p f=g p$, then $h_{X}(f)=h_{Y}(g)$.

Proof. It should be an easy estimate. The clue is that for $\ell>0$ and for any sequence $a_{n}$, we have $\lim \sup \frac{1}{n} \log \left(\ell a_{n}\right)=\lim \sup \frac{1}{n} \log a_{n}$. If $K \subset X$ and $K^{\prime} \subset Y$ are compact and $p(K)=K^{\prime}$, then there is a number $\ell>0$ such that $\left[\right.$ cardinality $\left.p^{-1}(y)\right] \leq \ell$ for all $y \in K^{\prime}$. In fact, we may choose $\ell$ such that, if $\delta>0$ is small enough, then $\mathrm{p}^{-1}\left(\mathrm{~B}_{\delta}(\mathrm{y})\right) \cap \mathrm{K}$ can be covered by at most $\ell \quad 2 \varepsilon$-balls centered at points in $\mathrm{p}^{-1}\left(\mathrm{~B}_{\delta}(\mathrm{y})\right) \cap \mathrm{K}$.

By the uniform continuity of f , we can find a $\delta_{0}(<\varepsilon)$ such that $x, x^{\prime} \in X$ and $\mathrm{d}\left(\mathrm{x}, \mathrm{x}^{\prime}\right)<\delta_{0}$ implies $\mathrm{d}\left(\mathrm{f}(\mathrm{x}), \mathrm{f}\left(\mathrm{x}^{\prime}\right)\right)<\varepsilon$, where $\epsilon>0$ is the one given in the definition of a metric covering. If $2 \delta<\delta_{0}$, it is easy to see that if $E^{\prime} \subset K^{\prime}$ is an ( $\mathrm{n}, \delta$ )-spanning set for g , then there exists an ( $\mathrm{n}, 2 \delta$ )-spanning set $\mathrm{E} \subset \mathrm{K}$ for $f$, such that card $E \leq \ell$ card $E^{\prime}$. So, we have $r_{K}(n, 2 \delta) \leq \ell r_{K^{\prime}}(n, \delta)$, hence $\bar{r}_{K}(\mathrm{f}, 2 \delta) \leq \overline{\mathrm{r}}_{\mathrm{K}^{\prime}}(\mathrm{g}, \delta)$ and $\mathrm{h}_{\mathrm{K}}(\mathrm{f}) \leq \mathrm{h}_{\mathrm{K}^{\prime}}(\mathrm{g})$.

On the other hand, if $\mathrm{E} \subset \mathrm{K}$ is ( $\mathrm{n}, \eta$ )-spanning (with $0<\eta<\varepsilon$ ) then $\mathrm{p}(\mathrm{E}) \subset \mathrm{K}^{\prime}$ is $(\mathrm{n}, \eta)$-spanning. So $\mathrm{r}_{\mathrm{K}^{\prime}}(\mathrm{n}, \eta) \leq \mathrm{r}_{\mathrm{K}}(\mathrm{n}, \eta)$, hence $\mathrm{h}_{\mathrm{K}^{\prime}}(\mathrm{g}) \leq \mathrm{h}_{\mathrm{K}}(\mathrm{f})$. Consequently $h_{K}(f)=h_{K^{\prime}}(g)$. Since we sup over all compact sets and since $p$ is surjective, we obtain $\mathrm{h}_{\mathrm{X}}(\mathrm{f})=\mathrm{h}_{\mathrm{Y}}(\mathrm{g})$.

We add one additional fact.

Proposition. If $X$ is compact and $f: X \rightarrow X$ is a homeomorphism, then $h\left(f^{n}\right)=|n| h(f)$.

For a proof, see [1] or [2].
§ II. - THE FUNDAMENTAL GROUP

Given a finitely generated group G and a finite set of generators $\mathcal{G}=\left\{g_{1}, \ldots, g_{r}\right\}$ of $G$, we define the length of an element $g$ of $G$ by $L_{G}(g)=$ minimum length of a word in the $g_{i}$ 's and the $g_{i}^{-1}$, s representing the element $g$.

It is easy to see that if $\mathcal{q}^{\prime}=\left\{g_{1}^{\prime}, \ldots, g_{s}^{\prime}\right\}$ is another set of generators, then :

$$
L_{C_{g}}(\mathrm{~g}) \leq\left(\max L_{\mathcal{C}}\left(\mathrm{g}_{\mathrm{i}}^{\prime}\right)\right) \mathrm{L}_{\mathrm{C}^{\prime}}(\mathrm{g}) .
$$

If $A: G \rightarrow G$ is an endomorphism, let :

$$
\gamma_{A}=\sup _{g \in G} \lim \sup \frac{1}{n} \log L_{C_{g}}\left(A^{n} g\right)=\sup _{g_{i} \in G} \lim \sup \frac{1}{n} \log L_{C_{G}}\left(A^{n} g_{i}\right)
$$

So $\gamma_{\mathrm{A}}$ is finite and by the inequality given above, $\gamma_{\mathrm{A}}$ does not depend on the set of generators.

Proposition 1. If $A: G \rightarrow G$ is an endomorphism and $g \in G$, define $\mathrm{gAg}^{-1}: G \rightarrow G$ by $\left[\mathrm{g} \mathrm{Ag}^{-1}\right](\mathrm{x})=\mathrm{gA}(\mathrm{x}) \mathrm{g}^{-1}$. We have $\gamma_{\mathrm{A}}=\gamma_{\mathrm{gAg}^{-1}}$.
Caution : $\left(\mathrm{gAg}^{-1}\right)^{\mathrm{n}} \neq \mathrm{gA}^{\mathrm{n}} \mathrm{g}^{-1}$.

First, we need a lemma.
Lemma 1. Let $\left(a_{n}\right)_{n \geq 1}$ and $\left(b_{n}\right)_{n \geq 1}$ be two sequences with $a_{n}$ and $b_{n} \geq 0$ and k be $>0$. We have :
i) $\lim \sup \frac{1}{n} \log \left(a_{n}+b_{n}\right)=\max \left(\lim \sup \frac{1}{n} \log a_{n}, \lim \sup \frac{1}{n} \log b_{n}\right)$
ii) $\lim \sup \frac{1}{n} \log k a_{n}=\lim \sup \frac{1}{n} \log a_{n}$
iii) $\lim \sup \frac{1}{n} \log a_{n} \leq \lim \sup \frac{1}{n} \log \left(a_{1}+\ldots+a_{n}\right) \leq \max \left(0, \lim \sup \frac{1}{n} \log a_{n}\right)$

Proof. Put $a=\lim \sup \frac{1}{n} \log a_{n}$ and $b=\lim \sup \frac{1}{n} \log b_{n}$.
i) The inequality $\max (a, b) \leq \lim \sup \frac{1}{n} \log \left(a_{n}+b_{n}\right)$ is clear.

If $c>\max (a, b)$, then we can find $n_{0} \geq 1$ such that $n \geq n_{0}$ implies $a_{n} \leq e^{n c}$ and $b_{n} \leq e^{n c}$. We obtain for $n \geq n_{0}$ :

$$
\frac{1}{n} \log \left(a_{n}+b_{n}\right) \leq \frac{1}{n} \log \left(2 e^{n c}\right)
$$

Hence $\lim \sup \frac{1}{n} \log \left(a_{n}+b_{n}\right) \leq \lim \sup \frac{1}{n} \log \left(2 e^{n c}\right)=c$.
ii) is clear.
iii) The inequality $a \leq \lim \sup \frac{1}{n} \log \left(a_{1}+\ldots+a_{n}\right)$ is clear.

Suppose $c>\max (0, a)$. We can find then $n_{0} \geq 1$ such that $a_{n} \leq e^{n c}$ for $n \geq n_{0}$. We have for $n \geq n_{0}$ :

$$
a_{1}+\ldots+a_{n} \leq \sum_{i=1}^{n_{0}-1} a_{i}+\frac{e^{\left(n+1-n_{0}\right) c}-1}{e^{c}-1} e^{n_{0} c}
$$

It follows clearly that $\lim _{n} \sup \frac{1}{n} \log \left(a_{1}+\ldots+a_{n}\right) \leq c$.

Proof of Proposition 1. If $x \in G$, we have :

$$
\left(\mathrm{g} \mathrm{Ag}^{-1}\right)^{\mathrm{n}}(\mathrm{x})=\mathrm{gA}(\mathrm{~g}) \ldots \mathrm{A}^{\mathrm{n}-1}(\mathrm{~g}) A^{\mathrm{n}}(\mathrm{x}) A^{\mathrm{n}-1}\left(\mathrm{~g}^{-1}\right) \ldots \mathrm{A}\left(\mathrm{~g}^{-1}\right) \mathrm{g}^{-1}
$$

Suppose first that $A^{n}(g)=e$ for some $n_{0}$, then it is clear that by lemma 1 i) :

$$
\lim \sup \frac{1}{n} \log L_{C}\left[\left(\operatorname{gAg}^{-1}\right)^{n}(x)\right] \leq \lim \sup \frac{1}{n} \log L_{C}\left(A^{n}(x)\right)
$$

If $A^{n}(g) \neq \mathrm{e}$ for each $\mathrm{n} \geq 1$, we have $\mathrm{L}_{\mathcal{C}}\left(\mathrm{A}^{\mathrm{n}}(\mathrm{g})\right) \geq 1$, for each $\mathrm{n} \geq 1$; hence $\lim \sup \frac{1}{\mathrm{n}} \log \mathrm{L}_{\mathcal{C}}\left(\mathrm{A}^{\mathrm{n}}(\mathrm{g})\right) \geq 0$. By lemma 1 i) \& iii), we obtain :

$$
\begin{aligned}
& \lim \sup \frac{1}{n} \log L_{C} \\
& \quad\left[\left(\operatorname{gAg}^{-1}\right)^{n}(x)\right] \\
& \leq \max \left(\lim \sup \frac{1}{n} \log L_{C}\left(A^{n}(g)\right), \lim \sup \frac{1}{n} \log L_{\mathcal{C}}\left(A^{n}(x)\right)\right)
\end{aligned}
$$

This gives us $\gamma_{\mathrm{gAg}^{-1}} \leq \gamma_{\mathrm{A}}$, and by symmetry, we have $\gamma_{\mathrm{gAg}}-1=\gamma_{\mathrm{A}}$.

For a compact connected differentiable manifold, we interpret $\pi_{1}(M)$ as the group of covering transformations of the universal covering space $\widetilde{M}$ of M . If $\mathrm{f}: \mathrm{M} \rightarrow \mathrm{M}$ is continuous, then there is a lifting $\tilde{\mathrm{f}}: \widetilde{\mathrm{M}} \rightarrow \tilde{\mathrm{M}}$. If $\tilde{\mathrm{f}}_{1}$ and $\tilde{f}_{2}$ are both liftings of $f$, then $\tilde{f}_{1}=6 \tilde{f}_{2}$ for some covering transformation $\theta$. A given lifting $\tilde{f}_{1}$ determines an endomorphism $\tilde{f}_{1 \mu}$ of $\pi_{1}(\mathrm{M})$ by the formula $\tilde{\mathrm{f}}_{1} \alpha=\tilde{\mathrm{f}}_{1 \#}(\alpha) \tilde{\mathrm{f}}_{1}$ for any covering transformation $\alpha$. If $\tilde{f}_{1}$ and $\tilde{f}_{2}$ are two liftings of f , then $\tilde{\mathrm{f}}_{1}=\theta \tilde{\mathrm{f}}_{2}$ for some covering transformation $\theta$ and $\tilde{\mathrm{f}}_{1} \alpha=\theta \tilde{\mathrm{f}}_{2} \alpha=\theta \tilde{\mathrm{f}}_{2 \#}(\alpha) \tilde{\mathrm{f}}_{2}=\theta \tilde{\mathrm{f}}_{2 \#}(\alpha) \theta^{-1} \tilde{\mathrm{f}}_{1}$, so $\tilde{\mathrm{f}}_{1 \#}=\theta \tilde{\mathrm{f}}_{2 \#} \theta^{-1}$ and $\gamma_{\tilde{\mathrm{f}}_{1 \#}}=\gamma_{\tilde{\mathrm{f}}_{2 \#}}$. Thus, we may define $\gamma_{\mathrm{f} \#}=\gamma_{\tilde{\mathrm{f} \#}}$ for any lifting $\tilde{f}: \widetilde{M} \rightarrow \tilde{M}$ of $f$. If $f$ has a fixed point $m_{0} \in M$, then there is also a map $f_{\#}$ : $\pi_{1}\left(\mathrm{M}, \mathrm{m}_{0}\right) \rightarrow \pi_{1}\left(\mathrm{M}, \mathrm{m}_{0}\right)$. The group $\pi_{1}\left(\mathrm{M}, \mathrm{m}_{0}\right)$ is isomorphic to the group of covering transformations of $\tilde{M}$ and $f$ may be lifted to $\tilde{f}$ such that $\tilde{f}_{\#}: \pi_{1}(M) \rightarrow \pi_{1}(M)$ is identified with $\mathrm{f}_{\#}: \pi_{1}\left(\mathrm{M}, \mathrm{m}_{0}\right) \rightarrow \pi_{1}\left(\mathrm{M}, \mathrm{m}_{0}\right)$ by this isomorphism. Thus $\gamma_{\mathrm{f} \#}$ makes coherent sense in the case that f nas a fixed point as well.

We suppose now that $M$ has a Riemannian metric and we put on $\tilde{M}$ a Riemannian metric by lifting the metric on $M$ via the covering map $p: \widetilde{M} \rightarrow M$. The map $p$ is then a metric covering and the covering transformations are isometries. We have the following lemma due to Milnor [8].

Lemma 2. Fix $x_{0} \in \tilde{N}$. There exist two constants $c_{1}, c_{2}>0$ such that for each $\mathrm{g} \in \pi_{1}(\mathrm{M})$, we have :

$$
c_{1} L_{C}(g) \leq d\left(x_{0}, g x_{0}\right) \leq c_{2} L_{C}(g)
$$

Proof [8]. Let $\delta=\operatorname{diam} M$, and define $N \subset \tilde{M}$ by $N=\left\{x \in \tilde{M} \mid d\left(x, x_{0}\right) \leq \delta\right\}$. We have $p(N)=M$. Remark that $\{g N\}_{g \in \pi_{1}(M)}$ is a locally finite covering of $\widetilde{M}$ by compact sets. Choose as a finite set of generators $\mathcal{C}=\left\{\mathrm{g} \in \pi_{1}(\mathrm{M}) \mid \mathrm{gN} \cap \mathrm{N} \neq \emptyset\right\}$ and notice that $\mathrm{g} \in \mathcal{C} \Leftrightarrow \mathrm{g}^{-1} \in \mathcal{C}$. Suppose $\mathrm{L}_{\mathrm{C}}(\mathrm{g})=\mathrm{n}$, then we can write $\mathrm{g}=\mathrm{g}_{1} \ldots \ldots \mathrm{~g}_{\mathrm{n}}$, with $\mathrm{g}_{\mathrm{i}} \mathrm{N}\left\ulcorner\mathrm{N} \neq \emptyset\right.$. It is easy to see then that $\mathrm{d}\left(\mathrm{x}_{0}, \mathrm{gx}_{0}\right) \leq 2 \delta \mathrm{n}$. Hence, we obtain :

$$
\mathrm{d}\left(\mathrm{x}_{0}, \mathrm{gx}_{0}\right) \leq 2 \delta \mathrm{~L}_{\mathrm{C}}(\mathrm{~g}) .
$$

Now, put $\nu=\min \{\mathrm{d}(\mathrm{N}, \mathrm{gN}) \mid \mathrm{N} \cap \mathrm{gN}=\emptyset\}$, by compactness $\nu>0$. Let k be the minimal integer such that $\mathrm{d}\left(\mathrm{x}_{0}, \mathrm{gx}_{0}\right)<\mathrm{k} \nu$. Along the minimizing geodesic from $\mathrm{x}_{0}$ to $g x_{0}$, take $\mathrm{k}+1$ points $\mathrm{y}_{0}=\mathrm{x}_{0}, \mathrm{y}_{1} \ldots \mathrm{y}_{\mathrm{k}-1}, \mathrm{y}_{\mathrm{k}}=\mathrm{gx}{ }_{0}$, such that $\mathrm{d}\left(\mathrm{y}_{\mathrm{i}}, \mathrm{y}_{\mathrm{i}+1}\right)<\nu$ for $\mathrm{i}=0, \ldots, \mathrm{k}-1$. Then, for $1 \leq \mathrm{i} \leq \mathrm{k}-1$, choose $\mathrm{y}_{\mathrm{i}}^{\prime} \in \mathrm{N}$ and $\mathrm{g}_{\mathrm{i}} \in \mathrm{G}$ such that $y_{i}=g_{i} y_{i}^{\prime}$, and put $g_{0}=e$ and $g_{k}=g$. We have $d\left(g_{i} y_{i}^{\prime}, g_{i+1} y_{i+1}^{\prime}\right)<\nu$, hence $g_{i}^{-1} g_{i+1} \in \mathcal{C}$. From $g=\left(g_{0}^{-1} g_{1}\right) \ldots\left(g_{k-1}^{-1} g_{k}\right)$, we obtain $L_{C_{i}}(g) \leq k$.

Since k is minimal, we have :

$$
\mathrm{L}_{\mathrm{C}}(\mathrm{~g}) \leq \frac{1}{\nu} \mathrm{~d}\left(\mathrm{x}_{0}, \mathrm{gx}_{0}\right)+1 \leq\left(\frac{1}{\nu}+\frac{1}{\mu}\right) \mathrm{d}\left(\mathrm{x}_{0}, \mathrm{gx}_{0}\right)
$$

where $\mu=\min \left\{d\left(x_{0}, g x_{0}\right) \mid g \neq e, g \in \pi_{1}(M)\right\}$.

Consider now $f: M \rightarrow M$ and let $\tilde{f}: \widetilde{M} \rightarrow \tilde{M}$ be a lifting of $f$. Applying the lemma above, we obtain, for each $x_{0} \in \tilde{M}$ :

$$
\gamma_{\mathrm{f}_{\#}}=\max _{\mathrm{g} \in \pi_{1}(\mathrm{M})} \lim \sup \frac{1}{\mathrm{n}} \log \mathrm{~d}\left(\mathrm{x}_{0}, \underset{\neq}{\widetilde{\mathrm{f}}_{\#}^{n}}(\mathrm{~g}) \mathrm{x}_{0}\right) .
$$

We next prove the following lemma :

Lemma 3. Given $x, y \in \widetilde{M}$, we have :

$$
\lim \sup \frac{1}{\mathrm{n}} \log \mathrm{~d}\left(\tilde{\mathrm{f}}^{\mathrm{n}}(\mathrm{x}), \tilde{\mathrm{f}}^{\mathrm{n}}(\mathrm{y})\right) \leq \mathrm{h}(\mathrm{f})
$$

Proof. Choose an arc $\alpha$ from $x$ to $y$. If $y_{1}, \ldots, y_{\ell} \in \alpha$ is ( $\left.n+1, \varepsilon\right)$-spanning for $\alpha$ and $\widetilde{\mathrm{f}}$, then $\widetilde{\mathrm{f}}^{\mathrm{n}}(\alpha) \subset \bigcup_{\mathrm{i}=1}^{\ell} \mathrm{B}\left(\tilde{\mathrm{f}}^{\mathrm{n}^{\prime}}\left(\mathrm{y}_{\mathrm{i}}\right), \varepsilon\right)$. Since $\widetilde{\mathrm{f}}^{\mathrm{n}}(\alpha)$ is connected, this implies diam $\tilde{\mathrm{f}}^{\mathrm{n}}(\alpha) \leq 2 \varepsilon \ell$. Hence :

$$
\mathrm{d}\left(\tilde{\mathrm{f}}^{\mathrm{n}}(\mathrm{x}), \tilde{\mathrm{f}}^{\mathrm{n}}(\mathrm{y})\right) \leq 2 \varepsilon \ell .
$$

By taking $\ell$ to be minimal, we obtain :

$$
\mathrm{d}\left(\tilde{\mathrm{f}}^{\mathrm{n}}(\mathrm{x}), \tilde{\mathrm{f}}^{\mathrm{n}}(\mathrm{y})\right) \leq 2 \varepsilon \mathrm{r}_{\alpha}(\mathrm{n}+1, \varepsilon) .
$$

From this, we get :

$$
\begin{gathered}
\lim _{\mathrm{n} \rightarrow \infty} \sup \frac{1}{\mathrm{n}} \log \mathrm{~d}\left(\widetilde{\mathrm{f}}^{\mathrm{n}}(\mathrm{x}), \widetilde{\mathrm{f}}^{\mathrm{n}}(\mathrm{y})\right) \leq \lim _{\mathrm{n} \rightarrow \infty} \sup \frac{1}{\mathrm{n}} \log \left[2 \in \mathrm{r}_{\alpha}(\mathrm{n}+1, \varepsilon)\right]=\overline{\mathrm{r}}_{\alpha}(\varepsilon) \leq \\
\leq h_{\alpha}(\tilde{\mathrm{f}}) \leq \mathrm{h}(\widetilde{\mathrm{f}})=\mathrm{h}(\mathrm{f}) .
\end{gathered}
$$

We are now ready to prove :

Theorem. If $\mathrm{f}: \mathrm{M} \rightarrow \mathrm{M}$ is a continuous map, then :

$$
h(f) \geq \gamma_{f_{\#}^{\#}}
$$

Proof. Since $\gamma_{f \#}=\max _{\mathrm{g} \in \pi_{1}(\mathrm{M})}\left[\lim \sup \frac{1}{\mathrm{n}} \log \mathrm{d}\left(\mathrm{x}_{0}, \tilde{f}_{\#}^{n}(\mathrm{~g}) \mathrm{x}_{0}\right)\right]$, we have to prove that for each $g \in \pi_{1}(M)$ :

$$
\lim \sup \frac{1}{\mathrm{n}} \log \mathrm{~d}\left(\mathrm{x}_{0}, \tilde{\mathrm{f}}_{\text {并 }}^{n}(\mathrm{~g}) \mathrm{x}_{0}\right) \leq \mathrm{h}(\mathrm{f})
$$

We have :

$$
\mathrm{d}\left(\mathrm{x}_{0}, \widetilde{\mathrm{f}}_{\#}^{\mathrm{n}}(\mathrm{~g}) \mathrm{x}_{0}\right) \leq \mathrm{d}\left(\mathrm{x}_{0}, \widetilde{\mathrm{f}}^{\mathrm{n}^{n}}\left(\mathrm{x}_{0}\right)\right)+\mathrm{d}\left(\tilde{\mathrm{f}}^{\mathrm{n}}\left(\mathrm{x}_{0}\right), \tilde{\mathrm{f}}_{\#}^{\mathrm{n}}(\mathrm{~g}) \tilde{\mathrm{f}}^{\mathrm{n}}\left(\mathrm{x}_{0}\right)\right)+\mathrm{d}\left(\tilde{\mathrm{f}}_{\#}^{\mathrm{n}}(\mathrm{~g}) \tilde{\mathrm{f}}^{\mathrm{n}}\left(\mathrm{x}_{0}\right), \tilde{\mathrm{f}}_{\#}^{\mathrm{n}}(\mathrm{~g}) \mathrm{x}_{0}\right)
$$

Since $\widetilde{\mathrm{f}}_{\#} \mathrm{n}_{\mathrm{n}}(\mathrm{g}) \widetilde{\mathrm{f}}^{\mathrm{n}}=\widetilde{\mathrm{f}} \mathrm{n}_{\mathrm{g}}$, and the covering transformations are isometries, we obtain :

$$
\mathrm{d}\left(\mathrm{x}_{0}, \widetilde{\mathrm{f}}_{\#}^{\mathrm{n}}(\mathrm{~g}) \mathrm{x}_{0}\right) \leq 2 \mathrm{~d}\left(\mathrm{x}_{0}, \widetilde{\mathrm{f}}^{\mathrm{n}}\left(\mathrm{x}_{0}\right)\right)+\mathrm{d}\left(\widetilde{\mathrm{f}}^{\mathrm{n}^{( }}\left(\mathrm{x}_{0}\right), \widetilde{\mathrm{f}}^{\mathrm{n}}\left(\mathrm{~g} \mathrm{x}_{0}\right)\right)
$$

Remark also that :

$$
\mathrm{d}\left(\mathrm{x}_{0}, \tilde{\mathrm{f}}^{\mathrm{n}}\left(\mathrm{x}_{0}\right)\right) \leq \mathrm{d}\left(\mathrm{x}_{0}, \tilde{\mathrm{f}}\left(\mathrm{x}_{0}\right)\right)+\mathrm{d}\left(\tilde{\mathrm{f}}^{\left(\mathrm{x}_{0}\right)}, \tilde{\mathrm{f}}^{2}\left(\mathrm{x}_{0}\right)\right)+\ldots+\mathrm{d}\left(\tilde{\mathrm{f}}^{\mathrm{n}-1}\left(\mathrm{x}_{0}\right), \tilde{\mathrm{f}}^{\mathrm{n}}\left(\mathrm{x}_{0}\right)\right)
$$

By applying lemma 3 and lemma 1 (together with the fact $h(f) \geq 0$ ), we obtain :

$$
\lim \sup \frac{1}{n} \log d\left(x_{0}, \tilde{\mathrm{f}}_{\#}^{\mathrm{n}}(\mathrm{~g}) \mathrm{x}_{0}\right) \leq \mathrm{h}(\mathrm{f})
$$

The proof of the following lemma is straigth forward.

and $p: G_{1} \rightarrow G_{2}$ are homomorphisms with $p$ surjective and $p A=B p:$

then, $\gamma_{\mathrm{A}} \geq \gamma_{\mathrm{B}}$.

Applying this lemma to the fundamental group of $M \bmod$ the commutator subgroup, we have :

so we obtain Manning's theorem [5].

Theorem. If $\mathrm{f}: \mathrm{M} \rightarrow \mathrm{M}$ is continuous, then $\mathrm{h}(\mathrm{f}) \geq \gamma_{\mathrm{f}_{1 *}}=\max \log \lambda$, where $\lambda$ ranges over the eigenvalues of $f_{1 *}$.

Remark 1. For $\alpha \in \pi_{1}\left(M, m_{0}\right)$, we denote by $[\alpha]$ the class of loops freely homotopic to $\alpha$. If M has a Riemannian metric, let $\ell([\alpha])$ be the minimum length of a (smooth) loop in this class. If $f: M \rightarrow M$ is continuous, $f[\alpha]$ is clearly well defined as a free homotopy class of loops. Let $G_{f}([\alpha])=\underset{n}{\lim } \sup \frac{1}{n} \log \left[\ell\left(f^{n}[\alpha]\right)\right]$ and let $G_{f}=\sup _{\alpha} G_{f}([\alpha])$.

It is not difficult to see that $G_{f} \leq \gamma_{f \#}$. In fact, we have $\ell\left(f^{n}[\alpha]\right) \leq$ $\leq \mathrm{d}\left(\mathrm{x}_{0}, \tilde{\mathrm{f}}_{\#}^{\mathrm{n}}(\alpha) \mathrm{x}_{0}\right)$, since the minimizing geodesic from $\mathrm{x}_{0}$ to $\tilde{\mathrm{f}}_{\#}^{\mathrm{n}}(\alpha) \mathrm{x}_{0}$ has an image in $M$ which represents $\mathrm{f}^{\mathrm{n}}[\alpha]$.

Remark 2. It occured to various people that Manning's theorem is a theorem about $\pi_{1}$.

Among these are Bowen, Gromov and Shub. Manning's proof can be adapted. The proof above is more like Gromov [4] or Bowen [2], but we take responsability for any error. At first, we assumed that f had a periodic point or we worked with $\mathrm{G}_{\mathrm{f}}$. After reading Bowen's proof [3], we eliminated the necessity for a periodic point.

Remark 3. If $x \in M$ and $\rho$ is a path joining $x$ to $f(x)$, we call $\rho_{\#}$ the homomorphism $\pi_{1}(\mathrm{M}, \mathrm{f}(\mathrm{x})) \rightarrow \pi_{1}(\mathrm{M}, \mathrm{x})$
$[\gamma] \longmapsto$. Since $\mathrm{f}_{\#}: \pi_{1}(\mathrm{M}, \mathrm{x}) \rightarrow \pi_{1}(\mathrm{M}, \mathrm{f}(\mathrm{x}))$, the composition $\rho_{\#} \mathrm{f}_{\#}$ is a homomorphism of $\pi_{1}(\mathrm{M}, \mathrm{x})$ into itself. This homomorphism can be identified with $\tilde{\mathrm{f}}_{\#}$ for a lifting $\tilde{f}$ of f . Thus our result is the same as Bowen's [3].

## § III. - SUBSHIFTS OF FINITE TYPE

Let $A=\left(a_{i j}\right)$ be $a k \times k$ matrix such that $a_{i j}=0$ or 1 , for $1 \leq i, j \leq k$, that is A is a 0-1 matrix. Such a matrix A determines a subshift of finite type as follows. Let $S_{k}=\{1, \ldots, k\}$ and let $\Sigma(k)=\underset{\prod_{i=-\infty}^{i}}{i=\infty} S_{k}^{i}$, where $S_{k}^{i}=S_{k}$ for each $\mathrm{i} \in \mathbb{Z}$. We put on $\mathrm{S}_{\mathrm{k}}$ the discrete topology and on $\Sigma(\mathrm{k})$ the product topology. The subset $\Sigma_{\mathrm{A}} \subset \Sigma(\mathrm{k})$ is the closed subset consisting of those bi-infinite sequences $\underline{b}=\left(b_{n}\right)_{n \in \mathbb{Z}}$ such that $a_{b_{i}} b_{i+1}=1$ for all $i \in \mathbb{Z}$.

Pictorially, we image $k$ boxes : $102 \ldots$ and a point which at discrete "time $n$ " can be in any one of the boxes. The bi-infinite sequences represent all possible histories of points. If we add the restriction that a point may move from box $i$ to box $j$, if and only if $a_{i j}=1$, then the set of all possible histories is precisely $\Sigma_{\mathrm{A}}$.

The shift $\sigma_{A}: \Sigma_{A} \rightarrow \Sigma_{A}$ is defined by $\sigma_{A}\left[\left(b_{n}\right)_{n \in \mathbb{Z}}\right]=\left(b_{n}^{\prime}\right)_{n \in \mathbb{Z}}$, where $b_{n}^{\prime}=b_{n+1}$ for each $n \in \mathbb{Z}$. Clearly, $\sigma_{A}$ is continuous. Let $C_{i} \subset \Sigma(k)$ be defined by $C_{i}=\left\{\underline{x} \in \Sigma(k) \mid x_{0}=i\right\}$. Let $D_{i}=C_{i} \cap \Sigma_{A}$, then $\mathscr{L}=\left\{D_{1}, \ldots, D_{k}\right\}$ is an open
cover of $\Sigma_{\mathrm{A}}$ by pairwise disjoint elements. For any $\mathrm{k} \times \mathrm{k}$ matrix $\mathrm{B}=\left(\mathrm{b}_{\mathrm{ij}}\right)$, we define the norm $\|B\|$ of $B$ by $\|B\|=\sum_{i, j=1}^{k}\left|b_{i j}\right|$. It is easy to see that $N_{n}\left(\sigma_{A}, d\right)=\operatorname{card}\left(\mathscr{d} \vee \ldots \vee \sigma_{A}^{-n+1} d\right) \leq\left\|A^{n-1}\right\|$ because the integer $a_{i j}^{(n)}$ is equal to the number of sequences $\left(i_{0}, \ldots, i_{n}\right)$ with $i_{e} \in\{1, \ldots, k\}, i_{0}=i, i_{n}=j$ and $a_{i_{\ell}} i_{\ell+1}=1$. So $\lim \sup \frac{1}{n} \log \left(N_{n}\left(\sigma_{A}, A\right)\right) \leq \lim \sup \frac{1}{n} \log \left\|A^{n-1}\right\|=\lim \sup \log \left\|A^{n}\right\|^{1 / n}$. This later number is recognizable as $\log$ (spectral radius A) or $\log \lambda$, where $\lambda$ is the largest modulus of an eigenvalue of $A$. In fact, we have :

Proposition. For any subshift of finite type $\sigma_{A}: \Sigma_{A} \rightarrow \Sigma_{A}$, we have $h\left(\sigma_{A}\right)=\log \lambda$, where $\lambda$ is the spectral radius of $A$.

Proof. We begin by noticing that each open cover $u$ of $\Sigma_{A}$ is refined by a cover of the form $\underset{i=-\ell}{\vee} \sigma_{A}^{-i} \mathbb{D}$. This implies, with the notations of section $I$ :

Hence, we obtain $: h\left(\sigma_{A}, u\right) \leq h\left(\sigma_{A}, \&\right)$.
This shows that : $\mathrm{h}\left(\sigma_{\mathrm{A}}\right)=\mathrm{h}\left(\sigma_{\mathrm{A}}, \sqrt{\infty}\right)$.
We now compute $h\left(\sigma_{A}, \mathcal{N}\right)$. We distinguish two cases.

First case. Each state $i=1, \ldots, k$ occurs. This means that $D_{i} \neq \emptyset$ for each $D_{i} \in \mathbb{D}$. It is not difficult to show by induction that we have in fact

$$
\mathrm{N}_{\mathrm{n}+1}\left(\sigma_{\mathrm{A}}, \mathfrak{d}\right)=\operatorname{card}\left(\mathbb{N} \vee \ldots \vee \sigma_{\mathrm{A}}^{-\mathrm{n}} \mathfrak{N}\right)=\left\|\mathrm{A}^{\mathrm{n}}\right\| .
$$

This proves the proposition in this case, as we saw above.

Second case. Some states do not occur. One can see that a state $i$ occurs, if, and only if, for each $\mathrm{n} \geq 0$, we have :

$$
\sum_{j=1}^{k} a_{i j}^{(n)}>0 \quad \text { and } \quad \sum_{j=1}^{k} a_{j i}^{(n)}>0 \quad \text { where } A^{n}=\left(a_{i j}^{(n)}\right)
$$

Notice that if $\sum_{j=1}^{k} a_{i j}^{\left(n_{0}\right)}=0$, then $\sum_{j=1}^{k} a_{i j}^{(n)}=0$ for $n \geq n_{0}$, this is because each $a_{\ell m}$ is $\geq 0$.
Now, we partition $\{1, \ldots, k\}$ into three subsets $\mathrm{X}, \mathrm{Y}, \mathrm{Z}$, where :

$$
\begin{aligned}
& X=\left\{i \mid \forall n \geq 0 \sum_{j=1}^{k} a_{i j}^{(n)}>0, \sum_{j=1}^{k} a_{j i}^{(n)}>0\right\} \\
& Y=\left\{i \mid \exists n>0 \quad \sum_{j=1}^{k} a_{i j}^{(n)}=0\right\}=\left\{i \mid \text { for } n \text { large } \sum_{j=1}^{k} a_{i j}^{(n)}=0\right\} \\
& Z=\{1, \ldots, k\}-(X \cup Y) .
\end{aligned}
$$

We have :

$$
Z \subset\left\{i \mid \text { for } n \text { large } \sum_{j=1}^{k} a_{j i}^{(n)}=0\right\}
$$

By performing a permutation of $\{1, \ldots, k\}$, we can suppose that we have the following situation :

$$
\{\underbrace{1, \ldots, t}_{X}, \underbrace{t+1, \ldots, s}_{Y}, \underbrace{s+1, \ldots, k}_{Z}\}
$$

If $B$ is a $k \times k$ matrix, we write :

$$
B=\left\{\begin{array}{lll}
B_{X X} & B_{X Y} & B_{X Z} \\
B_{Y X} & B_{Y Y} & B_{Y Z} \\
B_{Z X} & { }^{B_{Z Y}} & { }^{B_{Z Z}}
\end{array}\right.
$$

where $\mathrm{B}_{\mathrm{KL}}$ corresponds to the subblock of B have row indices in K and column indices in L .

It is easy to show that :

$$
\mathrm{N}_{\mathrm{n}+1}\left(\sigma_{\mathrm{A}}, \mathbb{d}\right)=\operatorname{card}\left(\& \vee \cdots \vee \sigma_{\mathrm{A}}^{-\mathrm{n}} \mathfrak{L}\right)=\left\|\left(\mathrm{A}^{\mathrm{n}}\right)_{\mathrm{X}}, \mathrm{X}\right\|
$$

On the oither hand, by the definition of $Y$ and $Z$, for $n$ large, $A^{n}$ has the form :

$$
A^{n}=\left(\begin{array}{ccc}
\left(A^{n}\right)_{X, X} & \left(A^{n}\right)_{X, Y} & 0 \\
0 & 0 & 0 \\
\left(A^{n}\right)_{Z, X} & \left(A^{n}\right)_{Z, Y} & 0
\end{array}\right)
$$

This implies that for $n$ large, $A^{n}$ and $\left(A^{n}\right)_{X, X}$ have the same non zero eigenvalues, in particular :

$$
\log \left(\text { spectral radius } A_{X, X}^{n}\right)=n \log \lambda .
$$

Remark also that we get, for $n$ large and $k \geq 1$ :

$$
\left(A^{k n}\right)_{X, X}=\left[\left(A^{n}\right)_{X, X}\right]^{k}
$$

This gives us, for n large :

$$
\lim _{k \rightarrow \infty} \sup \frac{1}{k n+1} \log N_{k n+1}\left(\sigma_{A}, \mathbb{Q}\right)=\lim _{k \rightarrow \infty} \sup \frac{1}{k n+1}\left\|\left[\left(A^{n}\right)_{X, X}\right]^{k}\right\|=\log \lambda
$$

This implies that :

$$
\log \lambda \leq h\left(\sigma_{A}, d\right)=\lim _{n \rightarrow \infty} \sup \frac{1}{n} \log N_{n}\left(\sigma_{A}, d\right)
$$

As we showed the reverse inequality, we have :

$$
\log \lambda=\mathrm{h}\left(\sigma_{\mathrm{A}}, \mathfrak{d}\right)=\mathrm{h}\left(\sigma_{\mathrm{A}}\right) .
$$

## § IV. - THE ENTROPY OF PSEUDO--ANOSOV DIFFEOMORPHISMS

Now we suppose that we have a compact, connected 2-manifold M without boundary with genus $\geq 2$, and a pseudo-Anosov diffeomorphism f: M $\rightarrow$ M. Hence there exists a pair $\left(\mathfrak{F}^{\mathrm{U}}, \mu^{\mathrm{U}}\right)$ and $\left(\mathfrak{F}^{\mathrm{S}}, \mu^{\mathrm{S}}\right)$ of transverse measured foliations with (the same) singularities such that $\mathrm{f}\left(\mathfrak{F}^{\mathrm{S}}, \mu^{\mathrm{S}}\right)=\left(\mathfrak{F}^{\mathrm{S}}, \frac{1}{\lambda} \mu^{\mathrm{S}}\right)$ and $\mathrm{f}\left(\mathfrak{F}^{\mathrm{u}}, \mu^{\mathrm{u}}\right)=\left(\mathfrak{F}^{\mathrm{u}}, \lambda \mu^{\mathrm{u}}\right)$ where $\lambda>1$. This means, in particular, that $f$ preserves the two foliations $\varlimsup^{s}$ and $\mathfrak{F}^{\mathrm{U}}$; it contracts the leaves of $\mathfrak{F}^{\mathrm{s}}$ by $\frac{1}{\lambda}$ and it expands the leaves of $\mathfrak{F}^{\mathrm{u}}$ by $\lambda$.

Let us recall that for any non trivial simple closed curve $\alpha$ we have $\log \lambda=G_{f}(\alpha) \quad$ (see exposé 9, prop. 19), hence we get $\log \lambda \leq G_{f} . \quad$ FFor the definition of $G_{f}$, look at the end of section $\amalg$. ]

Proposition. If f: $M \rightarrow M$ is pseudo-Anosov, then $h(f)=\gamma_{f \#}$. So in particular, $f$
has the minimal entropy of anything in its homotopy class. Moreover $h(f)=\log \lambda$, where $\lambda$ is the expanding factor of $f$.

Proof. Since $G_{f} \geq \log \lambda$, it suffices to show that $h(f) \leq \log \lambda$ for a pseudo-Anosov diffeomorphism f . To do this, we find a subshift of finite type $\sigma_{\mathrm{A}}: \Sigma_{\mathrm{A}} \rightarrow \Sigma_{\mathrm{A}}$ and a surjective continuous map $\Sigma_{A} \rightarrow M$ such that :

and $\log ($ spectral radias $A)=h\left(o_{A}\right)=\log \lambda$ for this same $\lambda$. Thus we will have $\log \lambda \leq G_{f} \leq \gamma_{\mathrm{f} \#} \leq \mathrm{h}(\mathrm{f}) \leq \mathrm{h}\left(\sigma_{\mathrm{A}}\right)$ or $\log \lambda \leq \mathrm{h}(\mathrm{f}) \leq \log \lambda$.

In the following, we construct $A$ and $\theta$ via Markov partitions.
First some definitions.

Definitions (compare exposé 9). A subset $R$ of $M$ is called a ( $\mathcal{F}^{\mathrm{S}}, \mathcal{F}^{\mathrm{U}}$ ) -rectangle or birectangle, if there exists an immersion $\varphi:[0,1] \times[0,1] \rightarrow \mathrm{M}$ whose image is R and such that :
$-\varphi \mid] 0,1\lceil\times j 0,1[$ is an imbedding ;

- $\forall \mathrm{t} \in[0,1], \varphi(\{\mathrm{t}\} \times[0,1])$ is included in a finite union of leaves and singularities of $z^{\mathrm{S}}$, and in fact in one leaf if $\left.\mathrm{t} \in\right] 0,1[$.
- $\forall t \in[0,1], \quad \varphi([0,1] \times\{t\})$ is included in a finite union of leaves and singularities of $\mathfrak{z}^{\mathrm{u}}$, and in fact in one leaf if $\left.t \in\right] 0,1[$.

We adopt the following notations :
int $R=\varphi(] 0,1[\times] 0,1[), \quad{ }_{\mathcal{F}}^{0} \mathrm{~S} R=\varphi(\{0\} \times[0,1]), \quad{\underset{\mathcal{F}}{ }}_{0} \mathrm{~S} R=\varphi(\{1\} \times[0,1])$,

Remark that Int $R$ is disjoint form $\underset{\mathscr{F} S}{\partial} R \cup \partial_{\mathfrak{F} u} R$, because $\left.\varphi \mid\right] 0,1[\times] 0,1[$ is an embedding.

We call a set of the form $\varphi(\{t\} \times[0,1])($ resp. $\varphi([0,1] \times\{t\}))$ a $\mathcal{F}^{\mathrm{S}}$-fiber (resp. a $\mathfrak{z}^{\mathrm{u}}$-fiber) of R . We will call a birectangle good if $\varphi$ is an imbedding.

If $R$ is good birectangle, a point $x$ of $R$ is contained in only one $\mathfrak{F}^{5}$-fiber which we will denote by $\mathfrak{F}^{S}(x, R)$. In the same way, we define $\mathfrak{F}^{u}(x, R)$.

birectangle (not good)

Remarks. 1) If $R$ is a $\mathcal{F}^{\mathrm{U}}$-rectangle (see exposé 9) and $\partial_{\tau}^{0} \mathrm{R}$ and $\partial_{\tau}^{1} \mathrm{R}$ are contained in a union of $\mathfrak{F}^{\mathrm{S}}$-leaves and singularities, it is easy to see that R is in fact a birectangle.
2) We used the word birectangle instead of rectangle, even though rectangle is the standard word in Markov partition, because this word was already used in exp. 9.
3) If $R_{1}$ and $R_{2}$ are birectangles and $R_{1} \cap R_{2} \neq \emptyset$, then it is a finite union of birectangles and possibly of some arcs contained in $\left(\partial_{\mathfrak{F} S} R_{1} \cup \partial_{\mathfrak{F}} \mathrm{R}_{1}\right) \cap\left(\partial_{\mathfrak{F} S} R_{2} \cup \partial_{\mathfrak{z}} R_{2}\right)$.

Moreover the birectangles are the closures of the connected components of Int $\mathrm{R}_{1} \cap$ Int $\mathrm{R}_{2}$.

If $R$ is a birectangle, we define the width of $R$ by :

$$
\mu^{2}(\mathrm{R})=\max \left\{\mu^{\mathrm{u}}\left(\mathfrak{F}^{\mathrm{S}} \text {-fiber }\right), \mu^{\mathrm{S}}\left(\mathfrak{F}^{\mathrm{u}} \text {-fiber }\right)\right\}
$$

Lemma 1. There exists $\varepsilon>0$ such that, if $R$ is a birectangle with $\mathcal{W}(R)<\varepsilon$, then it is a good rectangle.

Sketch of Proof. If a birectangle is contained in a coordinate chart of the foliations, then it is automatically a good birectangle. The existence of $\varepsilon$ follows from compactness.

Lemma 2. There exists $\varepsilon>0$ such that if $\alpha$ (resp. $\beta$ ) is an arc contained in a finite union of leaves and singularities of $\mathfrak{F}^{\mathrm{S}}\left(\right.$ resp. $\mathfrak{F}^{\mathrm{u}}$ ) with $\mu^{\mathrm{u}}(\alpha)<\varepsilon\left(\operatorname{resp} \cdot \mu^{\mathrm{S}}(\beta)<\varepsilon\right)$, then the intersection of $\alpha$ and $\beta$ is at most one point.

Definition of Markov partition. A Markov partition for the pseudo-Anosov diffeomorphism
$f: M \rightarrow M$ is a collection of birectangles $R=\left\{R_{1}, \ldots, R_{k}\right\}$ such that :
k

1) $\underset{i=1}{\cup} R_{i}=M$;
2) $R_{i}$ is a good rectangle ;
3) Int $R_{i} \cap$ Int $R_{j}=\emptyset$ for $i \neq j$;
4) If $x$ is in Int $\left(R_{i}\right)$ and $f(x)$ is in Int $\left(R_{j}\right)$, then $f\left(\mathcal{F}^{S}\left(x, R_{i}\right)\right) \subset \mathfrak{F}^{S}\left(f(x), R_{j}\right)$, and $\mathrm{f}^{-1}\left(\mathfrak{F}^{\mathrm{u}}\left(\mathrm{f}(\mathrm{x}), \mathrm{R}_{\mathrm{j}}\right)\right) \subset \mathcal{F}^{\mathrm{u}}\left(\mathrm{x}, \mathrm{R}_{\mathrm{i}}\right) ;$
5) If $x$ is in Int $\left(R_{i}\right)$ and $f(x)$ is in Int $\left(R_{j}\right)$, then

$$
f\left(\mathfrak{F}^{\mathrm{u}}\left(\mathrm{x}, \mathrm{R}_{\mathrm{i}}\right)\right) \cap \mathrm{R}_{\mathrm{j}}=\mathcal{F}^{\mathrm{u}}\left(\mathrm{f}(\mathrm{x}), \mathrm{R}_{\mathrm{j}}\right) \quad \text { and } \quad \mathrm{f}^{-1}\left(\mathfrak{F} \mathrm{~S}\left(f(x), \mathrm{R}_{\mathrm{j}}\right)\right) \cap \mathrm{R}_{\mathrm{i}}=\mathfrak{F}^{\mathrm{S}}\left(\mathrm{x}, \mathrm{R}_{\mathrm{i}}\right) ;
$$

This means that $f\left(R_{i}\right)$ goes across $R_{j}$ just one time.

We will show in next section how to construct a Markov partition for a pseudoAnosov diffeomorphism.

Given a Markov partition $R=\left\{R_{1}, \ldots, R_{k}\right\}$, we construct the subshift of finite type $\Sigma_{A}$ and the map $h: \Sigma_{A} \rightarrow M$ as follows. Let $A$ be the $k \times k$ matrix defined by $a_{i j}=1$ if $f\left(\right.$ Int $\left.R_{i}\right) \cap$ Int $R_{j} \neq \emptyset, \quad$ and $a_{i j}=0$ otherwise. If $\underline{b} \in \Sigma_{A}$, then $\bigcap_{i \in \mathbb{Z}} f^{-i}\left(R_{b}\right)$ is non empty and consists in fact a single point. This will follow from the following lemma.

Lemma 3. i) Suppose $a_{i j}=1$, then $f\left(R_{i}\right) \cap R_{j}$ is a non empty (good) birectangle which is a union of $\mathfrak{F}^{\mathrm{U}}$-fibers of $\mathrm{R}_{\mathrm{j}}$.
ii) Suppose moreover that $C$ is a birectangle contained in $R_{i}$ which is a union of $\mathfrak{F}^{u}$-fibers of $R_{i}$, then $f(C) \cap R_{j}$ is a non empty birectangle which is a union of $\mathcal{F}^{\mathrm{u}}$-fibers of $\mathrm{R}_{\mathrm{j}}$.
iii) Given $\underline{b} \in \Sigma_{A}$, for each $n \in \mathbb{N}, \bigcap_{i=-n}^{n} f^{-i}\left(R_{b_{i}}\right)$ is a non empty birectangle. Moreover, we have $w\left(\cap_{i=-n}^{n} f^{-i}\left(R_{b_{i}}\right)\right) \leq \lambda^{-n} \max \left\{v\left(R_{1}\right), \ldots, \vartheta\left(R_{k}\right)\right\}$

Proof. Since $a_{i j}=1$, we can find $x \in \operatorname{Int}\left(R_{i}\right) \cap f^{-1}\left(\operatorname{Int} R_{j}\right)$. We have $f\left(\not \mathcal{F}^{S}\left(x, R_{i}\right)\right) \subset$ $\subset \mathcal{J}^{\mathrm{S}}\left(\mathrm{f}(\mathrm{x}), \mathrm{R}_{\mathrm{j}}\right) \subset \mathrm{R}_{\mathrm{j}}$. Since each $\mathcal{J}^{\mathrm{U}}$-fiber of $\mathrm{R}_{\mathrm{i}}$ intersects $\mathcal{F}^{\mathrm{S}}\left(\mathrm{x}, \mathrm{R}_{\mathrm{i}}\right)$, we obtain that the image of each $\mathcal{F}^{u}$-fiber of $R_{i}$ intersects $R_{j}$. Moreover, by condition 5) $f\left[R_{i}-\partial \mathcal{Z}_{j} u R_{i}\right] \cap R_{j}$ is an union of $\mathcal{F}^{u}$-fibers of $R_{j}$, hence $f\left(R_{i}\right) \cap R_{j}=\overline{f\left(R_{i}-\partial R_{i}\right) \cap R_{j}}$ is also a union of $\mathfrak{F}^{\mathrm{u}}$-fibers of $\mathrm{R}_{j}$. This proves i). The proof of ii) is the same. To prove iii), remark first that it follows by induction on $n$ using ii) that
each set of the form $f^{n} R_{b_{i}} \cap f^{n-1}\left(R_{b_{i+1}}\right) \cap \ldots \cap R_{b_{i+n}} \quad$ is a non empty birectangle which is a union of $\mathcal{F}^{u}$-fibers of $R_{b_{i+n}}{ }^{i+1}$.In particular, ${\underset{i=-n}{n}}_{\cap}^{n} f^{-i}\left(R_{b_{i}}\right)$ is a non empty birectangle in $R_{b_{0}}$. The estimate of the width is clear.

By the lemma, if $\underline{b} \in \Sigma_{A}$, the set $\cap \cap_{i \in \mathbb{Z}} f^{-i}\left(R_{b_{i}}\right)$ is the intersection of a decreasing sequence of non empty compact sets, namely the sets $\cap_{i=-n}^{n} f^{-i}\left(R_{b_{i}}\right)$ for $n \in \mathbb{N}$. Hence $\underset{i \in \mathbb{Z}}{\cap} \mathbb{f}^{-i}\left(R_{b_{i}}\right)$ is non void. It is reduced to one point because $\left.\underset{\mathcal{V}}{\boldsymbol{i}} \underset{i=-n}{n} f^{-i}\left(R_{b_{i}}\right)\right)$ tends to zero as n goes to infinity.

The map $\theta: \Sigma_{A} \rightarrow M$ given by $\theta(\underline{b})=\cap_{i \in \mathbb{Z}} f^{-i}\left(R_{b_{i}}\right)$ is well defined, it is easy to see that it is continuous and that the following diagram commutes :

We show now that 6 is surjective. First remark that, for each $i=1, \ldots, k$, k the closure of Int $\left(R_{i}\right)$ is $R_{i}$. Hence $V=\bigcup \cup \operatorname{Int}\left(R_{i}\right)$ is a dense open set. By the Baire category theorem $U=\cap f^{-i}(V)$ is dense in $M$. If $x \in U$, then for each $n \in \mathbb{Z}$, the point $f^{n}(x)$ is in a unique $\operatorname{Int}\left(R_{b_{n}}\right)$ and $\underline{b}=\left\{b_{n}\right\}_{n \in \mathbb{Z}}$ is an element of $\Sigma_{\mathrm{A}}$. It is clear that $\theta(\underline{\mathrm{b}})=\mathrm{x}$. Thus $\theta\left(\Sigma_{\mathrm{A}}\right) \supset \mathrm{U}$. As $\Sigma_{\mathrm{A}}$ is compact and h continuous, we have $\theta\left(\Sigma_{A}\right)=M$.

Up to now, we have obtained that :

$$
\log \lambda \leq G_{f} \leq \gamma_{\mathrm{f} \mathrm{\#}} \leq \mathrm{h}(\mathrm{f}) \leq \mathrm{h}\left(\sigma_{\mathrm{A}}\right)=\log (\text { spectral radius of } \mathrm{A})
$$

All that remains is to show that :

$$
(\text { spectral radius of } A)=\lambda .
$$

To see this, we do the following thing. Put $y_{i}=\mu^{u_{(\Im) ~}^{s}}{ }^{s}$-fiber of $\left.R_{i}\right)$, it is clear that this quantity is independant of the $\mathfrak{F}^{s}$-fiber of $R_{i}$ and also $y_{i}>0$.

We have trivially the following equality :

$$
y_{j}=\sum_{i=1}^{k} \frac{y_{i}}{\lambda} a_{i j}
$$

which gives :

$$
\lambda y_{j}=\sum_{i=1}^{k} y_{i} a_{i j} \quad[\text { in particular } \lambda \text { is an eigenvalue of } A] .
$$

Hence, we obtain :

$$
\lambda y_{j} \geq\left(\sum_{i=1}^{k} a_{i j}\right) \min _{i} y_{i}
$$

This gives us :

$$
\lambda\left(\sum_{j} y_{j}\right) \geq\|A\| \min _{i} y_{i}
$$

where || || is the norm introduced in section III.
In the same way, we obtain for each $\mathrm{n} \geq 2$ :

$$
\lambda^{n}\left(\sum_{j} y_{j}\right) \geq \| A^{n^{n}} \min _{i} y_{i}
$$

Hence :

$$
\lambda \geq\left\|A^{n_{\|}}\right\|^{1 / n}\left(\frac{\min \left(y_{1}, \ldots, y_{k}\right)}{\sum_{1} y_{j}}\right)^{1 / n}
$$

Since $\min \left(y_{1}, \ldots, y_{k}\right)>0, \lim _{\mathrm{n} \rightarrow \infty}\left(\frac{\min \left(\mathrm{y}_{1}, \ldots, \mathrm{y}_{\mathrm{k}}\right)}{\sum_{\mathrm{j}} \mathrm{y}_{\mathrm{j}}}\right)^{1 / \mathrm{n}}=1$.
We thus obtain :

$$
\lambda \geq \lim _{n \rightarrow \infty}\left\|A^{n^{1}}\right\|^{1 / n}=\text { spectral radius of } A .
$$

Since $\lambda$ is an eigenvalue of $A$, we obtain :

$$
\lambda=\text { spectral radius of } \mathrm{A} .

## § V. - CONSTRUCTION OF MARKOV PARTITIONS FOR PSEUDO-ANOSOV DIFFEOMORPHISMS

In this section, we still consider $\mathrm{f}: \mathrm{M} \rightarrow \mathrm{M}$ a pseudo-Anosov diffeomorphism and we keep the notations of the last section. We sketch the proof of the following proposition.

Proposition. A pseudo-Anosov diffeomorphism has a Markov partition.

Using the methods given in exposé $9, \S \mathrm{~V}$, it is easy, starting with a family of transversals to $\mathfrak{F}^{\mathrm{U}}$ contained in $\mathfrak{F}^{\mathrm{S}}$-leaves and singularities, to construct a family $\Omega$ of $\mathfrak{F}^{\mathrm{L}}$-rectangles $\mathrm{R}_{1}, \ldots, \mathrm{R}_{\ell}$, such that:
i) $\underset{\mathrm{i}=1}{\cup \mathrm{R}_{\mathrm{i}}}=\mathrm{M}$;
ii) Int $\left(R_{i}\right) \cap \operatorname{Int}\left(R_{j}\right)=\emptyset$ for $i \neq j$;
iii) $f^{-1}\left(\bigcup_{i=1}^{\ell} \partial{ }_{\Im} u R_{i}\right) \subset \bigcup_{i=1}^{\ell} \partial \mathcal{F}^{d} R_{i}, \quad f\left(\bigcup_{i=1 ~}^{\ell} \partial{ }_{F} R_{i}\right) \subset \bigcup_{i=1}^{\ell} \partial R_{i}$.

By the remark following the definition of birectangles, the $R_{i}$ 's are birectangles since the system of transversals is contained in $\varlimsup^{\mathrm{S}}$-leaves and singularities.

We define for each $n$ a family of birectangles $R_{n}$ in the following way : the birectangles of $R_{n}$ will be the closures of the connected components of the non empty open sets contained in $\underset{i=-n}{V} f^{i} \stackrel{\circ}{R}=\left\{{ }_{i=-n}^{n} f^{i}\left(\right.\right.$ Int $\left.\left.R_{a_{i}}\right) \mid R_{a_{i}} \in \Omega\right\}$.

It is easy to see that ${ }^{R_{n}}$ still satisfies the properties i), ii) and iii) given above. Moreover, if $R \in R_{n}$, we have $\operatorname{vr}(R) \leq \lambda^{-n} \max \left\{\operatorname{VO}\left(R_{i}\right) \mid R_{i} \in R\right\}$. In particular, by lemma 1 of last section, for $n$ sufficiently large, each birectangle $R$ in $\Omega_{n}$ is a good one.

We assert that for $n$ sufficiently large $\Omega_{n}$ is a Markov partition. All that remains is to verify properties 4) and 5) of a Markov partition. It is an easy exercise to show that property 4) is a consequence of property iii) given above (see exposé 9 , lemme 10). By lemma 2 of section $I V$, if $n$ is sufficiently large and $R, R^{\prime} \in R_{n}$, then if $x \in R, f\left(\mathfrak{F}^{u}(x, R)\right)$ intersects in at most one point each $\mathfrak{F}^{s}$-fiber of $R^{1}$. Property 5) follows easily from the combination of this fact and of property 4).

Example of Markov partition on $T^{2}$. Let $A: T^{2} \rightarrow T^{2}$ be the linear map defined by $\mathrm{A}=\left(\begin{array}{ll}2 & 1 \\ 1 & 1\end{array}\right)$. Here $\mathrm{T}^{2}=\mathbb{R}^{2} / \mathbb{Z}^{2}$; and A acts on $\mathbb{R}^{2}$ preserving $\mathbb{Z}^{2}$, thus A defines a map of $T^{2}$. The translates of the eigenspaces of $A$ foliate $T^{2}$. The map $A$ on $T^{2}$ is Anosov. The foliation of $T^{2}$ corresponding to the eigenvalue $\frac{3+\sqrt{5}}{2}$ is expanded, the foliation corresponding to $\frac{3-\sqrt{5}}{2}$ is contracted.

We draw a fundamental domain with eigenspaces approximately drawn in.

The endpoints of the short stable manifold are on the unstable manifolds after equivalences have been made. Filling in to maximal rectangles gives the following picture.

The hatched line is the extension of the unstable manifold. Identified pieces are numbered similarly. One rectangle is given by $1,2,3,6$ and the other by 4,5. This
partition in two rectangles gives a Markov partition by taking intersections with direct and inverse images.

The construction of the Markov partition of a pseudo-Anosov diffeomorphism $\mathrm{f}: \mathrm{M} \rightarrow \mathrm{M}$, which preserves orientation and fixes the prongs of $\mathfrak{F}^{\mathrm{S}}$ and $\mathfrak{F}^{\mathrm{u}}$, is the same as in the example above. We sketch here the argument, hoping that it will aid the reader to understand the general case.

Since the unstable prongs are dense, we may pick small stable prongs whose endpoints lie on unstable prongs.

Roughly, the picture is :

We may extend these curves to maximal birectangles leaving the drawn curves as boundaries. By density of the leaves, every leaf crosses a small stable prong, so the rectangles obtained this way cover $\mathrm{m}^{2}$. The extension process requires that the unstable prongs be extended perhaps but the extension remains connected. Thus we have a partition by birectangles with boundaries the unions of connected segments lying on stable or unstable prongs. Consequently an unstable leaf entering the interior of a birectangle under f can't end in the interior, because the stable boundary has been taken to the stable boundary, etc...

but not

The only thing left is to make the partition sufficiently small. To do this, it is sufficient to take the birectangles obtained by intersections $f^{-n_{R}} \ldots, ~ \not \approx: \ldots, f^{n}(\Omega)$ for n sufficiently large.

## § VI. - PSEUDO-ANOSOV DIFFEOMORPHISMS ARE BERNOULLI.

A pseudo-Anosov diffeomorphism $\mathrm{f}: \mathrm{M} \rightarrow \mathrm{M}$ has a natural invariant probability measure $\mu$ which is given locally by the product of $\mu^{\mathrm{S}}$ restricted to plaques of $\mathfrak{\Re}^{\mathrm{u}}$ with $\mu^{\mathrm{u}}$ restricted to plaques of $\mathfrak{\Im}^{\mathrm{S}}$. The goal of this section is to sketch the proof of the following theorem.

Theorem. The dynamical system ( $\mathrm{M}, \mathrm{f}, \mu$ ) is isomorphic (in the measure theoretical sense) to a Bernoulli shift.

Recall that a Bernoulli shift is a shift $(\Sigma(\ell), \sigma)$ together a measure $\nu$ which is the infinite product of some probability measure on $\{1, \ldots, \ell\}$. Obviously, $\nu$ is invariant under $\sigma$, see [9],[11].

We will have to use the notion and properties of measure theoretic entropy, see [11] . We will also need the following two theorems on subshifts of finite type.

Let $A$ be a $k \times k$ matrix and $\left(\Sigma_{A}, \sigma_{A}\right)$ be the subshift of finite type obtained from it.

Theorem (Parry) [10]. Suppose that $A^{n}$ has all its ertries $>0$ for some $n$. Then, there is a probability measure $\nu_{\mathrm{A}}$ invariant under $\sigma_{\mathrm{A}}$ such that the measure
theoretic entropy $h_{\nu_{A}}\left(\sigma_{\mathrm{A}}\right)$ is equal to the topological entropy $\mathrm{h}\left(\sigma_{\mathrm{A}}\right)$. Moreover, $\nu_{\mathrm{A}}$ is the only invariant probability measure having this property, and $\left(\Sigma_{A}, \sigma_{A}, \nu_{A}\right)$ is a mixing Markov process.

Theorem (Friedman-Ornstein) [9] . A mixing Markov process is isomorphic to a Bernoulli shift. In particular, the ( $\left.\Sigma_{\mathrm{A}}, \sigma_{\mathrm{A}}, \nu_{\mathrm{A}}\right)$ above is Bernoulli.

Now we begin to prove that ( $\mathrm{M}, \mathrm{f}, \mu$ ) is Bernoulli. For this, we will use the subshift $\left(\Sigma_{A}, \sigma_{A}\right)$ and the map $\theta:\left(\Sigma_{A}, \sigma_{A}\right) \rightarrow(M, f)$ obtained from the Markov partition $R=\left\{R_{1}, \ldots, R_{k}\right\}$.

Lemma 1. There exists $n \geq 1$ such that $A^{n}$ has $>0$ entries.

Proof. Given $R_{i}$, we can find a periodic point $x_{i} \in \stackrel{\circ}{R}_{i}$, call $n_{i}$ its period. Consi-
 Moreover the $\mu^{s}$-length of $f^{\ell} n_{i}\left(\mathfrak{F}^{u}\left(x_{i}, R_{i}\right)\right)$ goes to infinity, since it is $\lambda^{\ell n_{i}} \mu^{\mathrm{s}}\left(\mathfrak{F}^{\mathrm{u}}\left(\mathrm{x}_{\mathrm{i}}, \mathrm{R}_{\mathrm{i}}\right)\right)$. This implies that $\mathrm{f}^{\ell \mathrm{n}_{\mathrm{i}}\left(\mathfrak{F}^{\mathrm{u}}\left(\mathrm{x}_{\mathrm{i}}, R_{\mathrm{i}}\right)\right) \cap_{\mathrm{k}}^{\mathrm{R}}}{ }_{j} \neq \emptyset, \forall \mathrm{j}=1, \ldots, \mathrm{k}$, for $\ell$ larg because the leaves of $\mathfrak{F}^{u}$ are dense. Now, if $n=\ell \cdot \prod_{i=1}^{k} n_{i}$ with $\ell$ large enough, we get $f^{n}\left(\stackrel{o}{R}_{i}\right) \cap \stackrel{o}{R}_{j} \neq \emptyset$ for each pair (i,j). Hence, we obtain that $a_{i j}^{(n)}>0$ for each $(i, j)$, where $A^{n}=\left(a_{i j}^{(n)}\right)$.

This lemma shows that $\left(\Sigma_{A}, \sigma_{A}, \nu_{A}\right)$ is Bernoulli by the results quoted above. All we have to do now is to prove that ( $M, f, \mu$ ) is isomorphic to $\left(\Sigma_{A}, \sigma_{A}, \nu_{A}\right)$.

Lemma 2. The measure theoretic entropy $h_{\mu}(f)$ is $\log \lambda$.

Proof. Since topological entropy is the supremum of measure theoretical entropies, see $[2,5]$, we have $h_{\mu}(\mathrm{f}) \leq \log \lambda$. Consider now the partition $\stackrel{\circ}{\AA}=\left\{\operatorname{Int} \mathrm{R}_{\mathrm{i}}\right\}$, its
$\mu$-entropy $h_{\mu}(\mathrm{f}, \stackrel{\circ}{\mathrm{R}})$ with respect to f is given by :

$$
h_{\mu}(f, \stackrel{\circ}{R})=\lim _{n}-\frac{1}{n} \Sigma a_{i j}^{(n)} \lambda^{-n} y_{i} x_{j} \log \left(\lambda^{-n} y_{i} x_{j}\right)
$$

where $y_{i}=\mu^{u}\left(\mathcal{F}^{\mathrm{S}}\right.$ fiber of $\left.R_{i}\right)$ and $\mathrm{x}_{j}=\mu^{\mathrm{S}}\left(\mathcal{F}^{\mathrm{u}}\right.$ fiber $\left.\mathrm{R}_{j}\right)$. As we saw and the end of section IV , $\frac{a_{i j}^{(n)}}{\lambda^{n}} \leq \frac{\left\|A^{n}\right\|}{\lambda^{n}}$ is bounded (by $\frac{\Sigma y_{j}}{\min y_{i}}$ ). This implies :

$$
\lim _{n}-\frac{1}{n} \Sigma a_{i j}^{(n)} \lambda^{-n} y_{i} x_{j} \log y_{i} x_{j}=0
$$

We have also :

$$
\Sigma \mathrm{a}_{\mathrm{ij}}^{(\mathrm{n})} \lambda^{-\mathrm{n}} \mathrm{y}_{\mathrm{i}} \mathrm{x}_{\mathrm{j}}=\Sigma \mathrm{y}_{\mathrm{j}} \mathrm{x}_{\mathrm{j}}=\Sigma \mu\left(\stackrel{\mathrm{o}}{\mathrm{R}}_{\mathrm{j}}\right)=\mu(\mathrm{M})=1
$$

By putting these facts together, we obtain : $\mathrm{h}_{\mu}(\mathrm{f}, \stackrel{\circ}{R})=\log \lambda$. Hence, $\mathrm{h}_{\mu}(\mathrm{f})=\log \lambda$, because $\log \lambda=\mathrm{h}_{\mu}(\mathrm{f}, \stackrel{\circ}{\mathrm{R}}) \leq \mathrm{h}_{\mu}(\mathrm{f}) \leq \mathrm{h}(\mathrm{f})=\log \lambda$.

Proof of the theorem. Put $\partial R=\bigcup_{i=1}^{k} \partial R_{i}$, we have $\mu(\partial R)=0$. This implies that the set $\mathbf{Z}=M-\underset{i \in \mathbb{Z}}{\cup} \mathbf{f}^{\mathbf{i}}(\partial R)$ has $\mu$-measure equal to one. We know by section IV that $\theta$ induces a (bicontinuous) bijection of $\theta^{-1}(Z)$ onto $Z$, we can then define a probability measure $\nu$ on $\Sigma_{A}$ by $\nu(B)=\mu\left(\theta\left[\theta^{-1}(Z) \cap B\right]\right)$ for each borel set $B \subset \Sigma_{A}$. It is easy to see that $\nu$ is $\sigma_{A}$ invariant ; moreover, $\theta$ gives rise to a measure theoritic isomorphism between $\left(\Sigma_{A}, \sigma_{A}, \nu\right)$ and $(M, f, \mu)$. In particular, $h_{\nu}\left(\sigma_{A}\right)=h_{\mu}(f)=$ $\log \lambda$. Since $\log \lambda$ is also the topological entropy of $\sigma_{A}$, we obtain from Parry's theorem that $\nu=\nu_{\mathrm{A}}$ and that $\left(\Sigma_{\mathrm{A}}, \sigma_{\mathrm{A}}, \nu\right)$ is a mixing Markov process. By the Friedman-Ornstein theorem, $\left(\Sigma_{A}, \sigma_{A}, \nu\right)$ is Bernoulli, hence $(M, f, \mu)$ is also Bernoulli.
