## FIXPOINT ALTERNATION: ARITHMETIC, TRANSITION SYSTEMS, AND THE BINARY TREE

J.C. Bradfield ${ }^{1,2}$

#### Abstract

We provide an elementary proof of the fixpoint alternation hierarchy in arithmetic, which in turn allows us to simplify the proof of the modal mu-calculus alternation hierarchy. We further show that the alternation hierarchy on the binary tree is strict, resolving a problem of Niwiński.

AMS Subject Classification. 68Q60, 03D55, 03D70, 03D80.

## 1. Introduction

The modal mu-calculus, or Hennessy-Milner logic with fixpoints, is a popular logic for expressing temporal properties of systems. It was first studied by Kozen in [11], and since then there has been much work on both theoretical and practical aspects of the logic. The feature of the logic that gives it both its simplicity and its power is that it is possible to have mutually dependent minimal and maximal fixpoint operators. This makes it simple, as the fixpoints are the only non-first-order operators, and powerful, as by such nesting one can express complex properties such as "infinitely often" and fairness. A measure of the complexity of a formula is the alternation depth, that is, the number of alternating blocks of minimal/maximal fixpoints. Formulae of alternation depth higher than 2 are notoriously hard to understand, and in practice one rarely produces them - not least because they are so hard to understand. For some years, it was not even known whether formulae of high alternation depth were necessary, that is, whether the alternation hierarchy was indeed a strict hierarchy of expressive power - a problem with several interesting ramifications, as well as its

[^0]intrinsic interest. In 1996 the strictness of the hierarchy was established by the present author [4]; independently, a slightly weaker result was shown by Lenzi [12]. The proof technique in [4] relied on the existence of a similar fixpoint alternation hierarchy in arithmetic with fixpoints (mu-arithmetic). The basic theory of muarithmetic constituted a somewhat surprising lacuna in existing work. On the one hand, there is an extensive theory of inductive definability, both over abstract structures (mainly by Moschovakis) and in the classical setting of recursion theory (by many people), with particular emphasis on the power of inductive definitions over classes of operators; on the other hand, first-order logic with fixpoints is a major topic in finite model theory, not least due to the Immerman-Vardi theorem. Despite these links, the fixpoint logic of the integers, and in particular the power of alternating fixpoints, appears not to have been studied in itself until the recursion-theoretic results by Lubarsky [13]. These highly technical results imply the arithmetic fixpoint alternation hierarchy by characterizing it in terms of another hierarchy, which has a complex definition. Thus the proof of [4] was not self-contained; furthermore, it was apparently not feasible to exhibit examples of strict alternation depth $n$ formulae, as the strict mu-arithmetic formulae of [13] are not constructible with any reasonable amounts of paper, ink and patience-there is only a high level description of the complex coding required, which is intended not simply to establish the hierarchy but also to give a precise characterization in terms of large admissible ordinals.

Another question is whether the alternation hierarchy remains strict on trees of bounded branching degree, in particular the binary tree. This is closely related to another long-standing alternation problem arising from Damian Niwiński's study of fixpoint algebras over trees. In his papers $[14,15]$ he has a fixpoint logic for such algebras in which formulae are built from $n$-ary function symbols, disjunction, and least and greatest fixpoint operators. The structures are infinite trees such that each node with $n$ children is labelled with some $n$-ary function symbol; a node satisfies the formula $f\left(\phi_{1}, \ldots, \phi_{n}\right)$ if the node is labelled by $f$ and the $i$-th child satisfies $\phi_{i}$; the fixpoints are taken over sets of nodes; a tree satisfies a formula if its root does. Niwiński established a number of results about such algebras, including intimate and now well-known relationships to automata theory. One result in particular concerns us here: he established a strict hierarchy of tree languages definable according to the number of alternating fixpoint quantifiers in the formula. In fact this hierarchy is closely connected to the hierarchy of Rabin indices in Rabin automata languages. However, in this study, as we have mentioned, the only boolean operator was union, and not intersection. Although intersection is easily added as a function symbol, many of the results rely on it not being a primitive of the language; and in particular, the alternation hierarchy theorem is not established for the languages with intersection. This problem has remained open.

In this paper we address these problems. The first result is an elementary proof of the alternation hierarchy in mu-arithmetic. This proof uses the standard technique for recursion-theoretic hierarchies; thus we remove the reliance on [13]. Furthermore, the proof constructs very simple examples of strict level $n$ formulae
of mu-arithmetic; and by using a simplified version of the techniques of [4], we are able to construct even simpler examples of strict level $n$ modal mu-calculus formulae. These examples are of just the form that one expects, if one is a modal mu-calculus hacker. In addition, we can also show that the formulae defining the existence of a winning strategy in a parity game are examples of strict formulae indeed, a referee has observed that this can be shown already from [4]. We then show how the proof can be carried through for the case of bounded branching degree systems, and then for the case of Niwinski's logic, so resolving the problem left open in [14].

## 2. Preliminaries

### 2.1. Modal mu-Calculus

We assume some familiarity with the modal mu-calculus, so in this section we give brief definitions to establish notations and conventions. Expository material on the modal mu-calculus may be found in $[2,16]$.

The modal mu-calculus, with respect to some countable set $\mathcal{L}$ of labels, has formulae $\Phi$ defined inductively thus: variables $Z$ and the boolean constants tt, ff are formulae; if $\Phi_{1}$ and $\Phi_{2}$ are formulae, so are $\Phi_{1} \vee \Phi_{2}$ and $\Phi_{1} \wedge \Phi_{2}$; if $\Phi$ is a formula and $l$ a label, then $[l] \Phi$ and $\langle l\rangle \Phi$ are formulae; and if $\Phi$ is a formula and $Z$ a variable, then $\mu Z . \Phi$ and $\nu Z . \Phi$ are formulae.

Note that we adopt the convention that the scope of the binding operators $\mu$ and $\nu$ extends as far as possible. For consistency, we also apply this convention to the $\forall$ and $\exists$ of first-order logic, writing $\forall x .(\exists y . P) \vee Q$ rather than the logicians' traditional $\forall x[\exists y[P] \vee Q]$.

Observe that negation is not in the language, but any closed mu-formula can be negated by using the usual De Morgan dualities- $\mu$ and $\nu$ are dual by $\neg \mu Z . \Phi(Z)$ $=\nu Z . \neg \Phi(\neg Z)$. Where necessary, we shall assume that free variables can be negated just by adjusting the valuation. We shall use $\Rightarrow$ etc. freely, though we must ensure that bound variables only occur positively.

We use the symbol $\mu$ to mean " $\mu$ or $\nu$ as appropriate".
Given a labelled transition system $\mathcal{T}=(\mathcal{S}, \mathcal{L}, \longrightarrow)$, where $\mathcal{S}$ is a set of states, $\mathcal{L}$ a set of labels, and $\longrightarrow \subseteq \mathcal{S} \times \mathcal{L} \times \mathcal{S}$ is the transition relation (we write $s \xrightarrow{l} s^{\prime}$ ), and given also a valuation $\mathcal{V}$ assigning subsets of $\mathcal{S}$ to variables, the denotation $\|\Phi\|_{\mathcal{V}}^{\mathcal{T}} \subseteq \mathcal{S}$ of a mu-calculus formula $\Phi$ is defined in the obvious way for the variables and booleans, for the modalities by

$$
\begin{aligned}
\|[l] \Phi\|_{\mathcal{V}}^{\mathcal{T}} & =\left\{s \mid \forall s^{\prime} . s \xrightarrow{l} s^{\prime} \Rightarrow s^{\prime} \in\|\Phi\|_{\mathcal{V}}^{\mathcal{T}}\right\} \\
\|\langle l\rangle \Phi\|_{\mathcal{V}}^{\mathcal{T}} & =\left\{s \mid \exists s^{\prime} . s \xrightarrow{l} s^{\prime} \wedge s^{\prime} \in\|\Phi\|_{\mathcal{V}}^{\mathcal{T}}\right\},
\end{aligned}
$$

and for the fixpoints by

$$
\begin{aligned}
\|\mu Z . \Phi\|_{\mathcal{V}}^{\mathcal{T}} & =\bigcap\left\{S \subseteq \mathcal{S} \mid\|\Phi\|_{\mathcal{V}[Z:=S]}^{\mathcal{T}} \subseteq S\right\} \\
\|\nu Z . \Phi\|_{\mathcal{V}}^{\mathcal{T}} & =\bigcup\left\{S \subseteq \mathcal{S} \mid S \subseteq\|\Phi\|_{\mathcal{V}[Z:=S]}^{\mathcal{T}}\right\}
\end{aligned}
$$

It is often useful to think of $\mu Z$ and $\nu Z$ as meaning respectively finite and infinite looping from $Z$ back to $\mu Z(\nu Z)$ as one "follows a path of the system through the formula". Examples of properties expressible by the mu-calculus are "always (on $a$-paths) $P$ ", as $\nu Z . P \wedge[a] Z$, "eventually (on $a$-paths) $P$ ", as $\mu Z . P \vee\langle a\rangle Z$, and "there is an $\{a, b\}$-path along which $b$ happens infinitely often", as $\nu Y . \mu Z .\langle b\rangle Y \vee$ $\langle a\rangle Z$. (For the latter, we can loop around $Y$ for ever, but each internal loop round $Z$ must terminate.)

There are several notions of alternation. The naive notion is simply to count syntactic alternations of $\mu$ and $\nu$, resulting in the following definition: a formula $\Phi$ is said to be in the classes $\Sigma_{0}^{S \mu}$ and $\Pi_{0}^{S \mu}$ iff it contains no fixpoint operators ( " $S$ " for "simple" or "syntactic"). The class $\Sigma_{n+1}^{S \mu}$ is the least class containing $\Sigma_{n}^{S \mu} \cup \Pi_{n}^{S \mu}$ and closed under the following operations: (i) application of the boolean and modal combinators; (ii) the formation of $\mu Z . \Phi$, where $\Phi \in \Sigma_{n+1}^{S \mu}$. Dually, to form the class $\Pi_{n+1}^{S \mu}$, take $\Sigma_{n}^{S \mu} \cup \Pi_{n}^{S \mu}$, and close under (i) boolean and modal combinators, (ii) $\nu Z . \Phi$, for $\Phi \in \Pi_{n+1}^{S \mu}$. Thus the examples above are in $\Pi_{1}^{S \mu}, \Sigma_{1}^{S \mu}$, and $\Pi_{2}^{S \mu}$ (but not $\left.\Sigma_{2}^{S \mu}\right)$ respectively. We shall say a formula is strict $\Sigma_{n}^{S \mu}$ if it is in $\Sigma_{n}^{S \mu}-\Pi_{n}^{S \mu}$.

For the modal mu-calculus, it is usual to define stronger notions of alternation $[8,14]$, which capture the true interdependency of alternating fixpoints, rather than just their syntactic position. In [4], the analysis is carried out for the strongest notion, that of [14], giving the classes called $\Sigma_{n}^{N \mu}$ in [4], as well as for the simple notion. In this paper, we shall not worry about the distinction, as the arguments apply whichever notion is used. Hence we shall just write $\Sigma_{n}^{\mu}$.

### 2.2. The arithmetic mu-Calculus

In [13] Lubarsky studies the logic given by adding fixpoint constructors to first-order arithmetic. Precisely, the logic ("mu-arithmetic" for short) has as basic symbols the following: function symbols $f, g, h$; predicate symbols $P, Q, R$; firstorder variables $x, y, z$; set variables $X, Y, Z$; and the symbols $\vee, \wedge, \exists, \forall, \mu, \nu, \neg, \in$. As with the modal mu-calculus, $\neg$ can be pushed inwards to apply only to atomic formulae, by De Morgan duality.

The language has expressions of three kinds, individual terms, set terms, and formulae. The individual terms comprise the usual terms of first-order logic. The set terms comprise set variables and expressions $\mu(x, X) . \phi$ and $\nu(x, X) . \phi$, where $X$ occurs positively in the formula $\phi$. Here $\mu$ binds both an individual variable and a set variable; henceforth we shall write just $\mu X . \phi$, and assume that the individual variable is the lower-case of the set variable. The formulae are built by the usual first-order construction, together with the rule that if $\tau$ is an individual term and $\Xi$ is a set term, then $\tau \in \Xi$ is a formula.

This language is interpreted over the structure $\mathbb{N}$ of first-order arithmetic with all recursive functions and predicates-in particular, let $\langle-,-\rangle,(-)_{0}$ and $(-)_{1}$ be standard pairing and unpairing functions. The semantics of the first-order connectives is as usual; $\tau \in \Xi$ is interpreted naturally; and the set term $\mu X . \phi(x, X)$ is interpreted as the least fixpoint of the functional $\mathbf{X} \mapsto\{m \in \mathbb{N} \mid \phi(m, \mathbf{X})\}$ (where $\mathbf{X} \subseteq \mathbb{N}$ ) .

The simplest examples of mu-arithmetic just use least fixpoints to represent an inductive definition. For example, $\mu X . x=0 \vee(x>1 \wedge(x-2) \in X)$ is the set of even numbers. Of course, the even numbers are also the complement of the odd numbers: the odd numbers are defined by $\mu X . x=1 \vee(x>1 \wedge(x-2) \in X)$, so by negating we can express the even numbers by means of a maximal fixpoint $\nu X . x \neq 1 \wedge(x>1 \Rightarrow(x-2) \in X)$. To produce natural examples involving alternating fixpoints is rather difficult, since even one induction is already very powerful, and most natural mathematical objects are simple.

One can define the syntactic alternation classes for arithmetic just as for the modal mu-calculus: first-order formulae are $\Sigma_{0}^{\mu}$ and $\Pi_{0}^{\mu}$, as are set variables. The $\Sigma_{n+1}^{\mu}$ formulae and set terms are formed from the $\Sigma_{n}^{\mu} \cup \Pi_{n}^{\mu}$ formulae and set terms by closing under (i) the first-order connectives $\wedge, \vee, \forall, \exists, \in$, and (ii) forming $\mu X . \phi$ for $\phi \in \Sigma_{n+1}^{\mu}$. If $\phi$ is $\Sigma_{n}^{\mu}$, then $\neg \phi$ is $\Pi_{n}^{\mu}$.

A crucial lemma is the following:
Lemma 2.1. $[4,13] A \Sigma_{n}^{\mu}$ formula of mu-arithmetic can be put into a normal form of the following shape:

$$
\tau_{n} \in \mu X_{n} \cdot \tau_{n-1} \in \nu X_{n-1} \cdot \tau_{n-2} \in \mu X_{n-2} \ldots \tau_{1} \in \mu X_{1} . \phi
$$

where $\phi$ is first-order-that is, a string of alternating fixpoint quantifiers, and a first-order body.
(See [4] for detailed definitions and proof.)
The analysis of [13] provides the following
Theorem 2.2. [13] The hierarchy of the sets of integers definable by $\Sigma_{n}^{\mu}$ formulae of the arithmetic mu-calculus is a strict hierarchy.

### 2.3. Summary of [4]

The results of this paper require the results and proof techniques of [4], so we now give a summary of these, skipping the fine details.

We define a recursively presented transition system (r.p.t.s.) to be a labelled transition system $(\mathcal{S}, \mathcal{L}, \longrightarrow)$ such that $\mathcal{S}$ is (recursively codable as) a recursive set of integers, $\mathcal{L}$ likewise, and $\longrightarrow$ is recursive. Henceforth we consider only recursively presented transition systems, with recursive valuations for the free variables. We have the following theorem, which is proved by a trivial translation of the semantics of the modal mu-calculus into mu-arithmetic:

Theorem 2.3. [4] For a modal mu-calculus formula $\Phi \in \Sigma_{n}^{\mu}$, the denotation $\|\Phi\|$ in any r.p.t.s. is a $\Sigma_{n}^{\mu}$ definable set of integers.

We also have the converse
Theorem 2.4. [4] Let $\phi(z)$ be a $\Sigma_{n}^{\mu}$ formula of mu-arithmetic. There is a r.p.t.s. $\mathcal{T}$ with recursive valuation $\mathcal{V}$ and a $\Sigma_{n}^{\mu}$ formula $\Phi$ of the modal mu-calculus such that $\phi\left((s)_{0}\right)$ iff $s \in\|\Phi\|_{\mathcal{V}}^{\mathcal{T}}$. (Thus if $\phi$ is not $\Sigma_{n-1}^{\mu}$-definable, neither is $\|\Phi\|$.)

This theorem is not inherently difficult; it is established by coding the evaluation of mu-arithmetic formulae into a r.p.t.s. and a modal mu-calculus formula, in such a way that arithmetic computation is handled by the transitions of the system, and the fixpoints of $\phi$ are handled by the fixpoints of $\Phi$. The proof is then a fairly straightforward induction. In this paper, we shall see a simplified version of this technique.

These two theorems establish the modal alternation hierarchy: use Theorem 2.4 to code an arithmetic strict $\Sigma_{n}^{\mu}$ set of integers by a strict $\Sigma_{n}^{\mu}$ modal mu-formula $\Phi$ on a r.p.t.s. $\mathcal{T}$; by Theorem 2.3, no $\Sigma_{n-1}^{\mu}$ modal formula can have the same denotation in $\mathcal{T}$, and so no $\Sigma_{n-1}^{\mu}$ modal formula is logically equivalent to $\Phi$.

### 2.4. Tree algebras

Niwiński's papers $[14,15]$ contain an extensive study of fixpoint algebras. For our purposes here, we consider just the most concrete versions, namely those over trees. Refer to [15], which is an excellent exposition, for further details and for the generalizations which do not concern us here.

Let $\Sigma$ be a signature containing a finite number of operators each with an arity. For example, take $\Sigma=\{a(-,-), b(-), c\}$, with one binary, one unary and one nullary operator. A tree over $\Sigma$ is a possibly infinite tree with nodes labelled by operators, such that a node labelled by $f$ has arity $(f)$ children.

Define a fixpoint logic over $\Sigma$ thus: variables $Z$, and tt and ff are formulae; conjunction $\wedge$ and disjunction $\vee$ of formulae are formulae; for each operator $f \in \Sigma$ with arity $n$ and formulae $\phi_{1}, \ldots, \phi_{n}, f\left(\phi_{1}, \ldots, \phi_{n}\right)$ is a formula; for a formula $\phi$ with free variable $Z, \mu Z . \phi$ and $\nu Z . \phi$ are formulae.

Given a particular tree $t$, this logic is interpreted over the set of nodes of $t$ in the obvious way: a node satisfies $f\left(\phi_{1}, \ldots \phi_{n}\right)$ if it is labelled by $f$ and its children satisfy respectively $\phi_{1}, \ldots \phi_{n}$. The fixpoints are interpreted as in the modal mucalculus: a formula with free variable $Z$ defines a function on the powerset lattice of nodes. We define the fixpoint alternation classes of formulae in the usual way.

We say that a tree satisfies $\phi$ if its root does. An important property of these logics is the "internalization property" [15]: given a tree $t$ and a node $n$ of $t$, the node $n$ satisfies a formula $\phi$ iff the subtree of $t$ rooted at $n$ satisfies $\phi$.

For examples of this logic with the signature above, we can consider the following. $\mu Z . a(Z, Z) \vee b(Z) \vee c$ defines the set of finite trees; $\nu Z . b(Z)$ defines the infinite linear tree $b \rightarrow b \rightarrow \cdots ; \nu Y . \mu Z . a(c, Y) \vee a(Z, Z) \vee b(Z)$ defines the set of trees such that on every path there are infinitely many $a$ nodes with a $c$ left child, and $c$ only occurs as the left child of $a$.

A tree algebra is then the set of all trees over a given signature, with the operations defined by the interpretations of the logical operators. We have no need
to consider the algebraic view, and can stick to the logic. The problem left open by Niwiński can be stated as follows: is there a signature $\Sigma$ such that the hierarchy of sets of trees definable by $\Sigma_{n}^{\mu}$ formulae is strict? For the case where intersection $\wedge$ is not a primitive symbol of the logic [14] showed strictness; however, the proof does not go through for the case with intersection, and indeed the exhibited hard $\Sigma_{n}^{\mu}$ formulae for the intersection-free case are in fact all equivalent to alternation depth 2 formulae with intersection.

## 3. A SIMPLE PROOF OF THE ALTERNATION HIERARCHY IN MU-ARITHMETIC

The first result of this paper is to observe that the alternation hierarchy theorem in mu-arithmetic can be proved simply along the lines of the proof of the strictness of the Kleene arithmetic hierarchy. The technique is to show that the truth of $\Sigma_{n}^{\mu}$ formulae can itself be expressed by a $\Sigma_{n}^{\mu}$ formula, and to use a diagonalization argument to show that this formula cannot be equivalent to any $\Pi_{n}^{\mu}$ formula.

Firstly, take a suitable Gödel numbering of mu-arithmetic. We consider only formulae without free set variables; $w \log$, we may assume that all encoded formulae are in normal form, and are normalized so that the free individual variables are $z_{0}, \ldots, z_{k}$, the first-order quantifiers bind $z_{k+1}, \ldots$, and for a formula of alternation depth $n$, the fixpoint variables are $\mathrm{X}_{n}, \ldots, \mathrm{X}_{1}$, with associated individual variables $x_{n}, \ldots, x_{1}$. We use sans-serif type to indicate that the variable is being seen as part of an encoded object-level formula; normal italic type indicates a meta-level variable. We use corner quotes to denote the Gödel coding. We also need coded assignments which map an encoded variable to a value: we write $[v / z]$ for the assignment that maps $z$ (strictly, the code $\ulcorner\mathbf{z}\urcorner$ ) to the integer $v$, and $a[v / z]$ for the updating of $a$ by $[v / z]$. We use double quotes to indicate the appropriate meta-language formalization of the informal statement inside the quotes.

Now suppose that $\operatorname{Sat}_{n}(x, y)$ is a formula of mu-arithmetic expressing the truth of $\Sigma_{n}^{\mu}$ formulae, so that if $\phi$ is a $\Sigma_{n}^{\mu}$ formula and $a$ an assignment of values $\vec{v}$ to the free variables $\vec{z}$ of $\phi$, then $\operatorname{Sat}_{n}(\ulcorner\phi\urcorner, a)$ is true just in case $\phi(\vec{v} / \vec{z})$ is true. We have the

Lemma 3.1. $\operatorname{Sat}_{n}\left(z_{0},\left[z_{0} / z_{0}\right]\right)$ is not equivalent to any $\Pi_{n}^{\mu}$ formula.
Proof. The proof is exactly as for the arithmetical hierarchy. Suppose the contrary, i.e. that $\neg \operatorname{Sat}_{n}\left(z_{0},\left[z_{0} / z_{0}\right]\right)$ is equivalent to some $\Sigma_{n}^{\mu}$ formula $\theta\left(z_{0}\right)$. Then we have $\theta(\ulcorner\theta\urcorner)$ iff $\neg \operatorname{Sat}_{n}\left(\ulcorner\theta\urcorner,\left[\ulcorner\theta\urcorner / z_{0}\right]\right)$ iff $\neg \theta(\ulcorner\theta\urcorner)$, which is a contradiction.

It remains to show that Sat $_{n}$ exists and is indeed a $\Sigma_{n}^{\mu}$ formula.
Theorem 3.2. $\mathrm{Sat}_{n}$ is a $\Sigma_{n}^{\mu}$ formula of mu-arithmetic, for $n>0$.
Proof. We start by constructing Sat $_{0}$, truth in first-order arithmetic, both as a $\Sigma_{1}^{\mu}$ formula and as a $\Pi_{1}^{\mu}$ formula. $\operatorname{Sat}_{0}(x, y)$ is defined as:

$$
\begin{aligned}
& \langle x, y\rangle \in \mu(w, W) . "(w)_{0}=\ulcorner P(\tau)\urcorner \text { and } \operatorname{pred}\left(\ulcorner P\urcorner, \operatorname{eval}\left(\ulcorner\tau\urcorner,(w)_{1}\right)\right) " \\
& \vee "(w)_{0}=\left\ulcorner\phi_{1} \wedge \phi_{2}\right\urcorner \text { and }\left(\left\langle\left\ulcorner\phi_{1}\right\urcorner,(w)_{1}\right\rangle \in W \wedge\left\langle\left\ulcorner\phi_{2}\right\urcorner,(w)_{1}\right\rangle \in W\right) " \\
& \vee "(w)_{0}=\left\ulcorner\phi_{1} \vee \phi_{2}\right\urcorner \text { and }\left(\left\langle\left\ulcorner\phi_{1}\right\urcorner,(w)_{1}\right\rangle \in W \vee\left\langle\left\ulcorner\phi_{2}\right\urcorner,(w)_{1}\right\rangle \in W\right) " \\
& \vee "(w)_{0}=\left\ulcorner\exists z_{i} . \phi_{1}\right\urcorner \text { and } \exists v .\left\langle\left\ulcorner\phi_{1}\right\urcorner,(w)_{1}\left[v / \mathbf{z}_{i}\right]\right\rangle \in W " \\
& \vee "(w)_{0}=\left\ulcorner\forall z_{i} \cdot \phi_{1}\right\urcorner \text { and } \forall v .\left\langle\left\ulcorner\phi_{1}\right\urcorner,(w)_{1}\left[v / z_{i}\right]\right\rangle \in W "
\end{aligned}
$$

where $\operatorname{eval}(t, a)$ is the recursive function which evaluates a coded term $t=\ulcorner\tau\urcorner$ under the variable assignment $a$, and $\operatorname{pred}(p, x)$ is the computable predicate which is true if the value $x$ satisfies the predicate coded by $p=\ulcorner P\urcorner$.

We have here skipped the details of the coding, which are standard. For example, if we look in more detail at the clause for $\forall$, it actually says:

$$
f\left((w)_{0}\right)=\ulcorner\forall\urcorner \wedge \forall v .\left\langle g\left((w)_{0}\right), h\left((w)_{1}, v, g^{\prime}\left((w)_{0}\right)\right)\right\rangle \in W
$$

where $f$ extracts the top-level connective of a coded formula, $g$ extracts the body of a $\forall$ formula and $g^{\prime}$ extracts the bound variable, and $h(a, v, z)$ takes the variable assignment $a$ and updates the variable whose code is $z$ by the value $v$. The fact that these functions $f, g, h$ are recursive is obvious, and since we allow ourselves all recursive functions as primitives, that is sufficient; but explicit definitions in standard arithmetic may be found in references such as [10].

It is clear that this fixpoint formula simply encodes directly the definition of truth in arithmetic. The formula is $\Sigma_{1}^{\mu}$, but since the encoded recursive function terminates on all arguments-it is just a definition by induction on the structure of formulae - it does not matter whether we use a minimal or maximal fixpoint to achieve the recursion. Thus we may also obtain $S_{a t}$ as a $\Pi_{1}^{\mu}$ formula.

In order to encode within mu-arithmetic the evaluation of formulae with fixpoints, it is necessary to have the same fixpoint structure in the Sat formula as in the formula it's evaluating. Recall that we assume pair-normal form, and suppose that we wish to evaluate $\Sigma_{n}^{\mu}$ formulae where $n$ is odd, that is, formulae of the form

$$
\begin{equation*}
\tau_{n} \in \mu \mathrm{X}_{n} \cdot \tau_{n-1} \in \nu \mathrm{X}_{n-1} \ldots \tau_{2} \in \nu \mathrm{X}_{2} \cdot \tau_{1} \in \mu \mathrm{X}_{1} \cdot \phi \tag{*}
\end{equation*}
$$

where $\phi$ is first-order. The interpretation of the pure first-order part of $\phi$ may be done with the $\Sigma_{1}^{\mu}$. version of $S^{2} t_{0}$-but $\phi$ may also now contain formulae $\tau \in \mathrm{X}_{i}$. We cannot code as integers the sets referred to by the $\mathrm{X}_{i}$, so they must be represented by set variables in the meta-language. We use the meta-level variable $X_{i}$ to represent the object variable $X_{i}$, and extend the body of Sat $_{0}$ by the clauses (for each $1 \leq i \leq n$ )

$$
\left.\vee "(w)_{0}=\left\ulcorner\tau \in X_{i}\right\urcorner \text { and } \operatorname{eval}\left(\ulcorner\tau\urcorner,(w)_{1}\right)\right) \in X_{i} " .
$$

Let Sat ${ }_{0}^{\prime}$ denote the adjusted Sat ${ }_{0}$.

With these adjustments, we have that $(*)$ is true with free variable assigment $a$ just in case

$$
\begin{aligned}
& \operatorname{eval}\left(\left\ulcorner\tau_{n}\right\urcorner, a\right) \in \mu X_{n} . \\
& \operatorname{eval}\left(\left\ulcorner\tau_{n-1}\right\urcorner, a\left[x_{n} / x_{n}\right]\right) \in \nu X_{n-1} \ldots . \\
& \quad \operatorname{eval}\left(\left\ulcorner\tau_{1}\right\urcorner, a\left[x_{n}, \ldots, x_{2} / \times_{n}, \ldots, x_{2}\right]\right) \in \mu X_{1} \\
& \quad \operatorname{Sat}_{0}^{\prime}\left(\ulcorner\phi\urcorner, a\left[x_{n}, \ldots, x_{1} / x_{n}, \ldots, x_{1}\right]\right) .
\end{aligned}
$$

Now we just parametrize on $(*)$ : let $f_{1}(x, y)$ be the function that given $x$ encoding a $\Sigma_{n}^{\mu}$ formula (*) and an assignment $y$, computes eval $\left(\left\ulcorner\tau_{n}\right\urcorner, y\right)$, and so on, and let $g(x)$ extract the body of $(*)$. Then we have $\operatorname{Sat}_{n}(x, y)$ in the form

$$
\begin{aligned}
& f_{n}(x, y) \in \mu X_{n} \cdot f_{n-1}\left(x, y\left[x_{n} / x_{n}\right]\right) \in \nu X_{n-1} \ldots \\
& \quad f_{1}\left(x, y,\left[x_{n}, \ldots, x_{2} / x_{n}, \ldots, x_{2}\right]\right) \in \mu X_{1} \cdot \operatorname{Sat}_{0}^{\prime}\left(g(x), y\left[x_{n}, \ldots, x_{1} / x_{n}, \ldots, \mathrm{x}_{1}\right]\right)
\end{aligned}
$$

which is $\Sigma_{n}^{\mu}$ as required. If $n$ is even, we use the $\Pi_{1}^{\mu}$ version of Sat ${ }_{0}$ instead.
The fact that $\mathrm{Sat}_{n}$ does indeed code truth is easily shown: show by induction on $i$ that each meta-level fixpoint set $X_{i}$ coincides with the object-level set $X_{i}$. The base case follows from the correctness of Sat ${ }_{0}^{\prime}$, and the induction step is easy.

It may be noted that we have also skipped details of what the functions $f_{1}$ etc. should do if given ill-formed arguments. Any convenient trick may be used; the details are unimportant.

## 4. THE SIMPLE EXAMPLES IN THE MODAL MU-CALCULUS

To construct examples of strict $\Sigma_{n}^{\mu}$ formulae in the modal mu-calculus, it would suffice to apply the general construction of Theorem 2.4 to Sat $_{n}$. However, Sat ${ }_{n}$ contains a large number of function symbols, and the translation would contain many labels. By specializing the general construction, we can eliminate most of these labels, and obtain very simple examples. The following presentation is self-contained, but terse; for a longer explanation of the technique, see [4].

We aim to construct a transition system $\mathcal{T}$ and a $\Sigma_{n}^{\mu}$ modal mu-calculus formula $\Phi$ such that the set of states satisfying $\Phi$ is defined by the strict $\Sigma_{n}^{\mu}$ arithmetic formula Sat ${ }_{n}$.

The transition system $\mathcal{T}$ should be viewed as a machine for evaluating arithmetic expressions in the same way that $\mathrm{Sat}_{n}$ does: the computation happening in the body of Sat ${ }_{0}^{\prime}$ will be dealt with by the definition of the transitions of $\mathcal{T}$, and the arithmetic fixpoints are translated into modal fixpoints in $\Phi$.

The states of $\mathcal{T}$ encode several pieces of information. Namely, a state $s$ contains: a formula $\psi_{s}$ of the form $(*)$, and a variable assignment $a_{s}$, and a pointer $p_{s}$ into $\psi_{s}$ which keeps track of where we are in the evaluation. We use the notation of $(*)$ to refer to parts of $\psi_{s}$.

The labels of $\mathcal{T}$ are used to distinguish various steps of computation; we shall start with enough labels to make the construction clear, and then argue the number down a little. In the interests of clarity, we shall use roman letters for the modal
labels: so $x$ is a meta-level arithmetic variable, x is an object-level arithmetic variable, and x is a modal label associated with x .

The transitions of $\mathcal{T}$ from a state $s$ are defined thus:

- if $p_{s}$ points at $\tau_{i}$ (or after $\mu \nu \mathrm{X}_{i+1}$., which we consider to be the same), then $s \xrightarrow{\mathrm{x}_{i}} s^{\prime}$ where $\psi_{s^{\prime}}=\psi_{s}$, and $a_{s^{\prime}}=a_{s}\left[\operatorname{eval}\left(\tau_{i}, a_{s}\right) / x_{i}\right]$ and $p_{s^{\prime}}$ points after $\mu \mathrm{X}_{i}$. That is, the term $\tau_{i}$ is evaluated in the current assignment, $X_{i}$ is set to its value, and we start evaluating the inner fixpoint.
Otherwise, $p_{s}$ points at a subformula of $\phi$. The transition from $s$ mimics the appropriate clause of Sat ${ }_{0}^{\prime}$. The $\psi$ component is not altered by any transition, and the a component is unchanged unless otherwise stated.
- If $p_{s}$ points at $P(\tau)$, then $s \xrightarrow{\mathrm{a}} s_{\mathrm{a}}$ ("a" for atom), where $s_{\mathrm{a}}$ is a special state with no structure, only if $P(\tau)$ is true with variable assignment $a_{s}$; otherwise there are no transitions from $s$.
- If $p_{s}$ points at $\phi_{1} \wedge \phi_{2}$, then $s \xrightarrow{\mathrm{c}} s_{k}$ (" c " for conjunction) for $k=1,2$, where $p_{s_{k}}$ points at $\phi_{k}$.
- If $p_{s}$ points at $\forall z_{i} . \phi_{1}$, then $s \xrightarrow{c} s_{k}$ (universal quantification is treated as conjunction) for $k \in \mathbb{N}$, where $p_{s_{k}}$ points at $\phi_{1}$, and $a_{s_{k}}=a_{s}\left[k / \mathbf{z}_{i}\right]$.
- If $p_{s}$ points at $\phi_{1} \vee \phi_{2}$, then $s \xrightarrow{\mathrm{~d}} s_{k}$ (" d " for disjunction) for $k=1,2$, where $p_{s_{k}}$ points at $\phi_{k}$.
- If $p_{s}$ points at $\exists \mathrm{z}_{i} . \phi_{1}$, then $s \xrightarrow{\mathrm{~d}} s_{k}$ (existential quantification is treated as disjunction) for $k \in \mathbb{N}$, where $p_{s_{k}}$ points at $\phi_{1}$, and $a_{s_{k}}=a_{s}\left[k / z_{i}\right]$.
- If $p_{s}$ points at $\tau \in \mathrm{X}_{i}$, then $s \xrightarrow{\mathrm{x}_{i}} s^{\prime}$, where $p_{s^{\prime}}$ points after $\mu \mathrm{X}_{i}$, , and $a_{s^{\prime}}=a_{s}\left[\operatorname{eval}\left(\tau, a_{s}\right) / \mathrm{x}_{i}\right]$. That is, the term $\tau$ is evaluated, copied to the input variable $\mathrm{x}_{i}$ of the fixpoint $X_{i}$, and evaluation of the fixpoint started.
It is clear that $\mathcal{T}$ is a recursively presented transition system.
Now consider the following modal mu-calculus formula:

$$
\begin{aligned}
\text { MuSat }_{n} \stackrel{\text { def }}{=} & \left\langle\mathrm{x}_{n}\right\rangle \mu X_{n} \cdot\left\langle\mathrm{x}_{n-1}\right\rangle \nu X_{n-1} \ldots\left\langle\mathrm{x}_{1}\right\rangle \mu X_{1} . \mu W \\
& \langle\mathrm{a}\rangle \mathrm{tt} \vee(\langle\mathrm{c}\rangle \mathrm{tt} \wedge[\mathrm{c}] W) \vee\langle\mathrm{d}\rangle W \\
& \vee\left\langle\mathrm{x}_{1}\right\rangle X_{1} \vee \ldots \vee\left\langle\mathrm{x}_{n}\right\rangle X_{n} .
\end{aligned}
$$

By the construction of $\mathcal{T}$, we have:
Theorem 4.1. $s \vDash \mathrm{MuSat}_{n}$ just in case $p_{s}$ points at $\psi_{s}$, and $\operatorname{Sat}_{n}\left(\left\ulcorner\psi_{s}\right\urcorner, a_{s}\right)$. Hence MuSat ${ }_{n}$ is a strict $\Sigma_{n}^{\mu}$ modal formula.
Proof. The proof is a special case of the proof of Theorem 2.4, the details of which are in [4].

MuSat $_{n}$ is already quite a simple formula, but it is interesting to try to simplify it further, which we shall do in stages.

Firstly, is it necessary to have the double occurrence of $\left\langle\mathrm{x}_{i}\right\rangle$, or can we remove the guards from the fixpoint formulae? Yes, we can: consider the formula

$$
\text { MuSat }_{n}^{\prime} \stackrel{\text { def }}{=} \mu X_{n}^{\prime} \cdot \nu X_{n-1}^{\prime} \ldots \mu X_{1}^{\prime} \cdot \mu W \cdot \Psi
$$

where $\Psi$ is formed from the body of $\mathrm{MuSat}_{n}$ by priming the $X_{i} \mathrm{~s}$. The relation between MuSat ${ }_{n}$ and MuSat ${ }_{n}^{\prime}$ is that $X_{n}^{\prime}=\ldots=X_{1}^{\prime}=X_{1}$ (note that in MuSat ${ }_{n}$, we have $X_{1} \supseteq X_{2} \cup \ldots \cup X_{n}$ ), and conversely $X_{i}=\left\langle\mathrm{x}_{i}\right\rangle X_{i}^{\prime}$ for $i=n, \ldots, 2$. The denotation of MuSat ${ }_{n}^{\prime}$ is still a strict $\Sigma_{n}^{\mu}$ set, since the denotation of MuSat ${ }_{n}$ is a projection of it.

Next, the occurrence of $\langle c\rangle$ tt is irritating. Its purpose is to assert that $p_{s}$ is indeed pointing at an $\wedge$ - or $\forall$-subterm of $\psi_{s}$-of course, $[\mathrm{c}] W$ is true at any state with no c-transitions from it. However, we can render it unnecessary by modifying $\mathcal{T}$ : if $s$ is any state other than an $\wedge$ - or $\forall$-subterm state, then add a transition $s \xrightarrow{c} s$. Since $W$ is a least fixpoint variable, if $W$ is true at a state with a c-loop, it is true by virtue of some other disjunct than [c] $W$, and it is not true if it was not true before the loop was added.

We can also eliminate the requirement for a separate a-transition, by modifying the modification: for all those states $s$ with an a-transition, remove the c-loop added in the previous paragraph; now [c]W is true at those states, so we can discard the $\langle\mathrm{a}\rangle$ tt clause.

Finally, we note that $W=X_{1}^{\prime}$, and they are adjacent least fixpoints, so we can amalgamate them; further, the job of the d transition can as well be done by $\mathrm{x}_{1}$, since they work on disjoint sets of states.

Hence we arrive at the following very simple example of a strict $\Sigma_{n}^{\mu}$ modal formula (replacing $X^{\prime}$ by $X$ again):

$$
\mathrm{MuSat}_{n}^{\prime \prime} \stackrel{\text { def }}{=} \mu X_{n} . \nu X_{n-1} \ldots \mu X_{1} \cdot[\mathrm{c}] X_{1} \vee\left\langle\mathrm{x}_{1}\right\rangle X_{1} \vee \ldots \vee\left\langle\mathrm{x}_{n}\right\rangle X_{n} .
$$

## 5. Relation to parity games

In a preliminary version of this paper, I showed that if one chooses to look at models with no action labels, but with atomic propositions, the above formula appears in a form that is the same as the formula describing the existence of a winning strategy in a parity game of rank $n$, and hence that formula is strict $\Sigma_{n}^{\mu}$.

When that paper was submitted to STACS, one of the referees pointed out that the strictness of the winning strategy formula can be shown directly from [4] and the game interpretation of modal mu-calculus [7], without requiring the explicit use of the arithmetic formula $\mathrm{Sat}_{n}$. As this is an elegant proof, I outline it here, and then comment on the similarities to MuSat.

A parity game of rank $n$ [7] is played on a directed graph with the following properties: every vertex belongs either to Player or Opponent, and every vertex has an index between 1 and $n$. If the current vertex belongs to player $A$, then $A$ moves by choosing a successor vertex. (In [7], the graph is bipartite so that Player and Opponent alternate, but this is not essential.) In a given play, Player wins if either Opponent gets stuck, or if the greatest index occurring infinitely often is even. ("greatest" is sometimes replaced by "least", e.g. in [17].) For simplicity, assume henceforth that $n$ is odd.

Given such a graph, let $P$ be true at Player vertices, $O$ be true at Opponent vertices, and $R_{i}$ true at vertices of index $i$. It can be shown $[7,17]$ that the modal mu-calculus formula

$$
\begin{aligned}
& \operatorname{Par}_{n} \stackrel{\text { def }}{=} \mu X_{n} \cdot \nu X_{n-1} \ldots \mu X_{1} . \\
& \quad\left(P \Rightarrow\left\rangle \bigwedge_{1 \leq i \leq n}\left(R_{i} \Rightarrow X_{i}\right)\right) \wedge\left(O \Rightarrow[] \bigwedge_{1 \leq i \leq n}\left(R_{i} \Rightarrow X_{i}\right)\right)\right.
\end{aligned}
$$

defines exactly the set of vertices from which Player has a winning strategy.
Now take a strict $\Sigma_{n}^{\mu}$ formula $\phi(z)$ of mu-arithmetic, and construct the r.p.t.s. $\mathcal{T}$ and modal formula $\Phi$ of Theorem 2.4. Given a $\Sigma_{n}^{\mu}$ modal formula, one can easily, and recursively, construct a parity game $G$ of rank $n$, whose vertices are pairs $(s, \Psi)$ of states of $\mathcal{T}$ and subformulae of $\Phi$, such that Player wins from $(s, \Psi)$ iff $s \models^{\mathcal{T}} \Psi$. Hence $(s, \Phi) \models^{G} \operatorname{Par}_{n}$ iff $\phi\left(s_{0}\right)$. Therefore $\left\|\operatorname{Par}_{n}\right\|^{G}$ is an arithmetic $\Sigma_{n}^{\mu}$-hard set, and so by Theorem 2.3 we conclude

Theorem 5.1. $\mathrm{Par}_{n}$ is a strict $\Sigma_{n}^{\mu}$ modal formula.
The alternative approach for showing the strictness of $\mathrm{Par}_{n}$ is to work from the transition system $\mathcal{T}$ of Theorem 4.1, and replace the action labels by atomic propositions, so that $P$ is true at disjunctive states, $O$ at conjunctive states, and $R_{i}$ at $X_{i}$ states. With a little manipulation along the lines of the construction of MuSat ${ }_{n}^{\prime \prime}$ from MuSat ${ }_{n}$, one obtains exactly the formula $\operatorname{Par}_{n}$ as the modal encoding of Sat $_{n}$. Thus we use Sat $_{n}$ explicitly, and use a specialization of the proof of Theorem 2.4. The STACS referee's suggestion avoids this work, and so produces the $\mathrm{Par}_{n}$ examples from [4] without using the simple proof of the mu-arithmetic hierarchy.

## 6. MODAL MU-CALCULUS ALTERNATION ON BOUNDED-BRANCHING SYSTEMS

Our next step is to show that the alternation hierarchy remains strict even on bounded-branching systems, and in particular on systems with a maximum branching degree of 2 .

Consider the formula

$$
\begin{aligned}
\operatorname{Hard}_{n} \stackrel{\text { def }}{=} \mu X_{n} . \nu X_{n-1} \ldots \mu X_{1} . & \langle\mathrm{a}\rangle \mathrm{tt} \vee\left(\langle\mathrm{c}\rangle \mathrm{tt} \wedge[\mathrm{c}] X_{1}\right) \\
& \vee\langle\mathrm{d}\rangle X_{1} \vee\left\langle\mathrm{x}_{1}\right\rangle X_{1} \vee \ldots \vee\left\langle\mathrm{x}_{n}\right\rangle X_{n}
\end{aligned}
$$

which is the same as MuSat ${ }_{n}^{\prime}$ except that we have amalgamated the adjacent fixpoints $X_{1}$ and $W$. The transition system on which we considered this formula has the convenient property that every state has outgoing transitions of only one label. However, many states had infinitely many successors; we need to address this. To solve Niwiński's problem, we shall also need to deal with the issue that the formula uses $n+2$ different labels; but this is a simple encoding issue.

For reasons that will become apparent when we consider Niwiński's trees, we should like to have a transition system with exactly two labels, $l, r$ such that every state has no successor or one $l$ and one $r$ successor.

Using standard techniques, we build a new transition system $\mathcal{T}_{n}^{\prime}$ in which the new labels code the old labels. For concreteness, let us say that if $s \xrightarrow{\alpha} t$ in $\mathcal{T}_{n}$, where $\alpha$ is a or $\mathrm{x}_{i}$, then in $\mathcal{T}_{n}^{\prime}$ we have

and if $s \xrightarrow{\beta} t_{i}$, where $\beta$ is c or d , and $1 \leq i \leq k$ for $k=2$ or $k=\infty$, according as $s$ has two successors (when coding a conjunction or disjunction) or infinitely many successors (when coding a box or diamond), then

where the $u$ states are new "junk" states, and $T_{\alpha}$ is a particular finite binary tree coding the label. For example, $T_{\mathrm{a}}$ might be the binary tree $\bullet, T_{\mathrm{c}}$ the tree $(\bullet, \bullet)$, $T_{\mathrm{d}}$ the tree $((\bullet, \bullet), \bullet)$, and so on. Let $\Psi_{\alpha}$ be a modal formula characterizing $T_{\alpha}$ : for example, $\Psi_{\text {c }}$ would be $\langle l\rangle[] \mathrm{ff} \vee\langle r\rangle[] \mathrm{ff}$.

We now need to translate the formula $\operatorname{Hard}_{n}$ for the new system. Obviously we can translate $\left\langle\mathrm{x}_{i}\right\rangle \Phi$ into $\langle r\rangle \Psi_{\mathrm{x}_{i}} \wedge\langle l\rangle \Phi$ etc., but the translation of the c and d modalities requires introducing additional fixpoints. The (sometimes infinite) branching box $\langle\mathrm{c}\rangle \mathrm{tt} \wedge[\mathrm{c}] X_{1}$ becomes $\langle r\rangle \Psi_{\mathrm{c}} \wedge[l] \nu Y$. $[l] Y \wedge[r] X_{1}$; and the branching diamond $\langle\mathrm{d}\rangle X_{1}$ becomes $\langle r\rangle \Psi_{\mathrm{d}} \wedge\langle l\rangle \mu Y .\langle r\rangle X_{1} \vee\langle l\rangle Y$.

Since the construction of $\mathcal{T}_{n}^{\prime}$ is recursive, the new formula $\operatorname{Hard}_{n}^{\prime}$ still denotes an arithmetic $\Sigma_{n}^{\mu}$-hard set of states. Unfortunately, $\operatorname{Hard}_{n}^{\prime}$ is now a modal $\Sigma_{n+1}^{\mu}$ formula, owing to the introduction of the new fixpoints! This is still sufficient to establish the hierarchy, since it cannot be equivalent to any modal $\Pi_{n}^{\mu}$ formula. However, we could also obtain a direct proof that it cannot be equivalent to any modal $\Pi_{n+1}^{\mu}$ formula, since it can be shown, by extending an analysis of [3], that on a bounded degree recursive transition system a modal $\Sigma_{n}^{\mu}$ formula denotes a set of at most arithmetic $\Sigma_{n-1}^{\mu}$ complexity.

We now have the result
Theorem 6.1. There is a class of transition systems with branching degree $\leq 2$ on which the modal mu-calculus alternation hierarchy is strict.

## 7. Alternation in tree algebras

Owing to the way in which we have set up $\mathcal{T}_{n}^{\prime}$, the transfer to tree algebras is almost immediate. We take the signature $\Sigma$ with a binary function symbol $a$
and a nullary function symbol $c$. The left and right children of a node labelled $a$ correspond to the $l$ and $r$ successors of a non-leaf node in $\mathcal{T}_{n}$; thus a tree over this signature is a transition system of the form specified for $\mathcal{T}_{n}^{\prime}$, and conversely the unwinding $\mathcal{T}_{n}^{\prime \prime}$ of $\mathcal{T}_{n}^{\prime}$ is a tree over this signature. Since unwinding is a recursive operation, we can say that given a $\Sigma_{n}^{\mu}$ tree mu-formula, the set of nodes of $\mathcal{T}_{n}^{\prime \prime}$ satisfying it is of arithmetic complexity $\Sigma_{n-1}^{\mu}$. However, we can translate Hard ${ }_{n}^{\prime}$ into a tree formula $\operatorname{Hard}_{n}^{\prime \prime}$ :

$$
\begin{aligned}
\mu X_{n} \ldots \mu X_{1} \cdot & a\left(\mathrm{tt}, \psi_{\mathrm{a}}\right) \\
& \vee a\left(\nu Y \cdot a\left(Y, X_{1}\right), \psi_{\mathrm{c}}\right) \\
& \vee a\left(\mu Y \cdot a(Y, \mathrm{tt}) \vee a\left(\mathrm{tt}, X_{1}\right), \psi_{\mathrm{d}}\right) \\
& \vee a\left(X_{1}, \psi_{\mathrm{x}_{1}}\right) \vee \ldots \vee a\left(X_{n}, \psi_{\mathrm{x}_{n}}\right)
\end{aligned}
$$

where $\psi_{\alpha}$ is the translation of $\Psi_{\alpha}$, for example $\psi_{\mathrm{a}}=c, \psi_{\mathrm{c}}=a(c, c), \psi_{\mathrm{d}}=a(a(c, c), c)$ and so on. Hence the nodes of $\mathcal{T}_{n}^{\prime \prime}$ satisfying $\operatorname{Hard}_{n}^{\prime \prime}$ are exactly those that are the unwindings of states of $\mathcal{T}_{n}^{\prime}$ satisfying $\operatorname{Hard}_{n}^{\prime}$; and hence this set is arithmetic $\Sigma_{n}^{\mu}$-hard. It follows that for any formula $\phi$ of lower alternation depth, there is a node on which $\phi$ and $\operatorname{Hard}_{n}^{\prime \prime}$ disagree. Now by the crucial fact that a node satisfies a formula iff the subtree rooted at that node satisfies it (the "internalization property" of [15]), there is a tree on which $\phi$ and $\operatorname{Hard}_{n}^{\prime \prime}$ disagree. Hence we have

Theorem 7.1. The fixpoint alternation hierarchy over the Niwinski tree logic with signature $\{a(-,-), c\}$ and intersection is strict.

Of course, as for the intersection-free result of [15], this signature is the minimal signature: we need at least one constant with arity 2 , and at least one other symbol. With a more generous signature, the coding is less messy, and simpler hard formulae can be presented, as was done in [6] (for the signature $\{a(-,-), b(-)\}$ ).

It is interesting to note that even though we are establishing a hierarchy with intersection, the hard formulae do not themselves use intersection once they are expressed in the tree logic; they need only the "implicit" intersection given by the binary symbol $a$. However, unlike the hard formulae of [15], which are in fact all equivalent to level $\Sigma_{2}^{\mu}$ formulae in the intersection-full hierarchy, the implicit conjunction conjoins different fixpoints. One may also compare the disjunctive formulae of [9].

## 8. Remarks

Although this approach has solved the problem of Niwiński, one might reasonably object to it on aesthetic grounds. It should be possible to solve a problem about a fairly weak logic on the binary tree without resorting to the use of arithmetic and Gödel encodings. Indeed, one might hope that the diagonalization argument, used to prove this hierarchy as many others, could be carried out directly on the trees. This hope is not vain: by the time this work was presented at

FICS, Arnold [1] had discovered an elegant technique which uses a form of diagonalization on the binary tree, together with some basic (ultra-)metric space theory, to show the hardness of all the example formulae produced by myself, Lenzi, and others.

I especially thank A. Simpson, who suggested looking at a simple proof of the mu-arithmetic hierarchy along these lines. Thanks also to I. Walukiewicz, who pointed me at the parity game formulae. In addition to the referee who provided the improved proof for parity game formulae, other referees provided helpful suggestions; I am grateful to them. I am supported by an Advanced Fellowship (AF/97/0322) from the United Kingdom Engineering and Physical Sciences Research Council; also BRICS, the Danish National Research Foundation Centre for Basic Research In Computer Science, is supporting my visit to Aarhus. The material of Sections 3-5 was first presented at STACS '98 [5]; Sections 6-7 were presented at FICS in Brno in 1998 [6].
