INTRODUCTION
シェッニニッニッニニニニ

The latest achievements on the renormalization of Lagrangian models involving gauge fields，mostly due to G．＇t Hooft，B．W．Lee，M．Veltman， J．Zinn Justin（1），were primarily based on the use of a gauge invariant regularization procedure，the most popular of which being the so called dimen－ sional regularization（2）．The gauge structure could thus conveniently be respected by fulfilling the so called Slavnor identities（3）through the renormalization procedure．There resulted finite Green＇s functions which couid not however be directly given an interpretation relevant to an operator theory in some Fock space，were it be in a perturbative sense，because of the lack of the finite mass renormalizations which would have been necessary for this purpose．As will be seen here，an operator incerpretation is quite convenient for any discussion involving asymptotic concepts concerning e．g，the unitarity of the $S$ operator，the construction of gauge invariant local operators etc

We shall treat here the simplest model involving gauge fields in which no infrared problem occurs，namely the abelian Higgs－Kibble model（4） within the class of gauges advocsted by $G$ ．＇ c Hooft．The algebraic complications which occur in the non abelian cases are deferred to later publications．

We shall make full use of the combinatorial knowledge of renormalized perturbation theory that has been acquired through the work of $W$ ．Zimmermann （effective Lagrangians normal products，Wilson expansions），J，H．Lowenstein and YMP Lam（7）（renormalized action principle），which has been successfully applied in other cases（massive quantum electrodynamics（8），$\sigma$ models abelian Higgs Kibble model in the Stueckelberg gauge（ ）

This well developed machinery，which relies on the locality and power counting properties of perturbation theory，is most effectively put to，（ll） work by intensive use of the implicit function theorem for formal power series through which，as we shall see，most symmetry aspects of the perturbation series can be read off on the classical Lagrangian on which the theory is basec， including the possible occurence of anomalies．This possibly surprising state－ ment will be widely illustrated in the present work and in reviews now in pre－ paration ${ }^{(12)}$

The main reason why such a favourable situation prevails in the present case is that the model is almost entirely specified by an invariance property
even after the introduction of the necessary Faddeev-Popov ghosts (13) Namely, at the classical level, the Lagrangian is invariant under transformations of the supergauge type ${ }^{(14)}$, which we have called Slavnov transformatiuns. In the abelian case treated here, one has however also to impose the full degeneracy of the ghost masses in order to implement spontaneous breaking. This is a particular feature of the abelian case which in a sense makes things more complicated,

Section I is thus devoted to a study of sume crucial aspects of the tree approximation. The role of the invariance under Slavnov transformations and the particuliar expression of spontaneous breaking are stressed,

In Section II the model is define d to all orders of a perturbation expansion in powers of a parameter, $\hbar$, which counts the numbt $t_{R}$ of loops in Feynman diagrams. Namely, we show that both renormalized Slavnov identities and the normalization conditions on Green's functions which hold in the tree approximation can be fulfilled to all orders. The compactness of the proofs is due to a repeated use of the implicit function theorem for formal power series $\langle 11\rangle$. The logic of the construction also makes clear how anomalies, which do net occur in the present model, can be produced.

In Section III, one proves the independence of the physical scattering operat r against a change of the parameters which label the gauge function, by suitably generalizing the argument given by J. H , Lowenstein and B. Schroer (8) in the case of massive quantum electrodynamics.

Section IV is devoted to a direct combinatorial proof of the unitarity of the physical $S$ operator

Several appendices are devoted to a number of technical questions: Appendix I deals with the structure of the Slavnov identities at the classical level in the non abelian case.
Appendir $I I$ is devoted to a brief description of the implicit function theorem for formal power series (11),

Appendices III, $I V$ and $V$ give some computational details which would have

```
obscured the line of argument in the body of the article.
    Appendix VI deals with the construction of some local gauge invariant
    operators of dimension smaller than or equal to four
    Appendix VII extends the theory to quadratic gauges odd under charge
    conjugation.
```

As is well known, a classical Lagrangian, $\mathcal{L}^{c l}$, which will be assumed to be of the renormalimable type, define the tree approximation of a quantum Green's functional

$$
\begin{equation*}
Z(J)=\exp \frac{e^{\prime}}{\hbar} \mathcal{Z}^{c}(J) \tag{1}
\end{equation*}
$$

where $J$ denotes collectively a set of sources linearly coupled to the field variables $\varphi$ from which $\mathcal{L}^{c e}$ is constructed. The ${ }_{c}$ Legendre transform (15) $\Gamma(\varphi)$ of the connected Green's functional $\mathcal{Z}^{C}(J)$ defined through

$$
Z^{c}(\underline{J})=\prod(\underline{\varphi})+\int(\underline{I} \varphi)(x) d x
$$

coincides with $\mathcal{L}^{d}$ in the lowest approximation of a perturbative expansion in powers of $h$, and, in higher orders, generates "proper" Feynman graphs.

Let us now consider a classical Lagrangian

$$
\begin{align*}
\mathcal{L}_{(1)}^{d}(J) & \equiv \mathcal{L}_{(1)}(\underline{\varphi})+\frac{J \cdot \varphi}{\mathcal{G}^{2}} \\
& =\mathcal{L}_{\operatorname{inv}}(\varphi)-\frac{\varphi}{2 \alpha}+\underline{I}(\underline{\varphi} \tag{3}
\end{align*}
$$

where $\mathcal{L}_{\text {inv }}(\underline{\varphi})$ is invariant under local abelian gauge transformations of the second kind ;

$$
\begin{equation*}
\delta \varphi(x)=\int \frac{\delta \varphi(x)}{\delta \Lambda(y)} \delta \Lambda(y) d y \tag{4}
\end{equation*}
$$

$G$ is a gauge function which breaks gauge invariance, and $\alpha$ is a numerical parameter, as they occur for instance in quantum electrodynamics. Noether's theorem yields the following Ward identity:

$$
\int d x\left[\underline{J}(x) \cdot \frac{\delta \underline{\varphi}(x)}{\delta \Lambda(y)}-m(x, y) \frac{G(x)}{\alpha}\right]=0
$$

where the substitution

$$
\begin{equation*}
\underline{\varphi}=\frac{\delta Z_{v}^{c}(\underline{J})}{\delta \underline{J}} \tag{6}
\end{equation*}
$$

has to be made, and where

$$
\begin{equation*}
M(x, y)=\frac{\delta g(x)}{\delta \Lambda(y)} \tag{7}
\end{equation*}
$$

is the kernel of a field dependent differential operator of hyperbolic character whenever $G$ is a perturbed version of the divergence of the gauge vector field associated with the gauge transformations under consider ration. We shall fr m now on limit ourselves to this situation.
The Ward identity (5) can conveniently be solved for $G$ upon introducing scalar charged Faddeev-Popov $(\phi \pi)$ ghost fields ${ }^{(13)}$ and the corresponding sources into the initial Lagrangian

$$
\begin{align*}
\mathcal{L}^{d}(x) & =\mathcal{L}_{\operatorname{inv}}(x)-\frac{1}{\alpha}\left(\frac{\xi^{2}(x)}{2}+\int d y \bar{c}(y) M(x, y) c(x)\right)+[J \cdot \varphi+\bar{\xi} c+\xi \bar{c}](x) \\
& =\mathscr{L}(\underline{\varphi}, c, \bar{c})(x)+[\underline{J} \cdot \underline{\varphi}+\xi c+\xi \bar{\varepsilon}](x) \tag{8}
\end{align*}
$$

The Fermi statistics conventionally assigned to these fields while presserving locality introduces new sources of indefinite metric into the quantum interpretation of such a system and, at the same time exhibits crucial properties connected with the structure of the gauge transformations, which are best observed in the non abelian case described in Appendix $I$. The new Ward identity reads :

$$
W(x)\left(z^{c}\right)=\int d y\left[\int(y)-\frac{\delta f(x)}{\delta A(x)}-\frac{1}{\alpha} m(y, x) \zeta(y)-\frac{1}{\alpha} \int d z \bar{c}(z) \frac{\delta m(y, z)}{\delta A(x)} c(y)\right]=0(9)
$$

Integrating through $\bar{c}$ yields the so-called Slavnov identity ${ }^{(3)}$, which, in the present, abeliant case, reads :

$$
\begin{equation*}
S\left(Z_{c}\right)=\int d x\left[\xi(x) \xi(x)+\int d y J(x) \cdot \frac{\delta \varphi(x)}{\delta N(y)} \bar{e}(y)\right]=0 \tag{10}
\end{equation*}
$$

where use has been made of the equations of motion for the $\phi \mathbb{\pi}$ fields,
and of their anticomutativity, whereby the last term in the Ward edentity (9) drops out in view of the abelianness of the gauge transfermations. In the non abelian case treated in Appendix I, this last term contributes however in a way which is characterized in terms of the structure constants of the Lie algebra involved.

The Slavnov identity can be interpreted as expressing the invariance of $\mathcal{L}$ under the following transformations of the supergavge type ${ }^{(18)}$, which we shall call Slavnov transformations :

$$
\begin{align*}
& \delta_{\lambda} \varphi(x)=\lambda \int \frac{\delta \varphi(x)}{\delta \Lambda(y)} \bar{c}(y) d y \\
& \delta_{\lambda} c(x)=\lambda G(x)  \tag{11}\\
& \delta_{\lambda} \bar{c}(x)=0
\end{align*}
$$

where $\lambda$ is an infinitesimal, space time independent, gauge parameter of the Fermi type. The vanishing of the variation of $\bar{C}$ is due to the abelian character of the gauge transformations and is suitably altered in the non abelian case as shown in Appendix I. The Fermi character of the $\phi \pi$ field linearizes the gauge "group" since

$$
\begin{align*}
& \delta_{\lambda_{1}} \delta_{\lambda_{2}} \varphi(x)=0 \\
& \delta_{\lambda_{1}} \delta_{\lambda_{2}} \bar{c}(x)=0  \tag{12}\\
& \delta_{\lambda_{1}} \delta_{\lambda_{2}} c(x)=\lambda_{\lambda} \lambda_{2} \int M(y, x) \bar{c}(y) d y
\end{align*}
$$

so that

$$
\int^{2}\left(z_{2}\right) \equiv \int d x d y E(y) M(y, x) E(x)=0
$$

0

$$
\begin{equation*}
\left(j^{2}-j^{2} \cdot j\right)\left(z_{a}^{2}\right) \Rightarrow 0 \tag{14}
\end{equation*}
$$

One should realize the lack of equivalence, in general, between the Ward identity (5) and the Slavnov identity (10) : if one adds to $\mathcal{L}$ a breaking term of the form

$$
\begin{equation*}
-\frac{B}{\alpha} \tag{15}
\end{equation*}
$$

such that

$$
\begin{equation*}
\frac{\delta B(x)}{\delta \Lambda(y)}=\eta(x, y) g(x) \tag{16}
\end{equation*}
$$

where $\Omega$ is a possibly field dependent differential operator which does not upset the hyperbolic character of $M$, the Lagrangian

$$
\begin{align*}
\mathcal{L}_{B}^{A} & =\mathcal{L}_{\text {inv }}(x)-\frac{1}{2}\left(\frac{g^{2}(x)}{2}+B(x)+\int d y \bar{a}(y)(m(x, y)+M(x, y)) c(x)\right)  \tag{17}\\
& +\underline{J}(x) \cdot \varphi(x)+\bar{\xi}^{2}(x) c(x)+\xi(x) \bar{c}(x)
\end{align*}
$$

will lead to the same Slavnov identity whereas the Ward identity is modetied according to

$$
\begin{align*}
W^{(B)}\left[\left(z_{c}\right]\right. & =\int d y\left[J(y) \cdot \frac{\delta \varphi(y)}{\delta \Lambda(x)}-\frac{1}{\alpha}(M(y, x)+M(y, x)) G(y)\right. \\
& \left.-\frac{1}{\alpha} \int d z \bar{C}(z) \frac{\delta(M(y, z)+M(y, z))}{\delta \Lambda(x)} c(y)\right]=0 \tag{18}
\end{align*}
$$

This pathological situation is due to the abelianness of the gauge transformations which insures the absence from the Slavnov identity of a contribution involving the last term of the Ward identity.
A concrete example of this phenomenon will be given in the context of the abelian Higgs Kibble model treated within a family of linear, charge conjugation odd gauges.
The basic fields and sources are given in Table I

BEHAVIOUR UNDER
CHARGE CONJUGATION

| $\varphi_{1}$ | even | $J_{1}$ |
| :--- | :--- | :--- |
| $\varphi_{2}$ | $\left.\begin{array}{c}\text { odd } \\ A_{\mu} \\ c \\ c\end{array}\right\} \phi \pi{ }_{\text {ghosts }}$ | odd <br> even <br> even |

TABLE I : Fields and Sources

One may choose for the Slavnov transformation:

$$
\begin{aligned}
& \delta \varphi_{1}=-\lambda e_{1}^{0} \varphi_{2} \bar{c} \\
& \delta \varphi_{2}=+\lambda e_{2}^{0}\left(\varphi_{1}+v^{0}\right) \bar{c} \\
& \delta A_{\mu}=\lambda \partial_{\mu} \bar{c} \\
& \delta c=\lambda\left(a^{0} \partial_{\mu} A_{\mu}+\rho^{0} \varphi_{2}\right) \\
& \delta \bar{c}=0
\end{aligned}
$$

where $V^{0}$ is a field translation parameter $e_{\lambda}^{0}, e_{2}^{0}$ are charge parameters, $Q^{0}$ and $\rho^{0}$ characterize the gauge function. The corresponding Slavnov identity reads:

$$
\left.\left.\begin{array}{rl}
S\left(Z_{c}\right) & \equiv \int d x\left\{J_{\mu} \partial_{\mu} \delta_{\xi} Z_{c}-e_{1}^{0} J_{1} \delta_{J_{2}} Z_{c} \delta_{\xi} Z_{e}+e_{2}^{0} J_{2}\left(\delta_{J_{1}} Z_{c} \delta_{\xi} Z_{c}\right.\right. \\
& +v^{0} \delta_{\xi} Z \tag{20}
\end{array}\right)-\bar{\xi}\left[Q \partial_{\mu}^{0} \delta_{J_{\mu}} Z_{c}+\rho^{0} \delta_{J_{2}} Z_{c}\right]\right\}(x)=0 \quad l
$$

Eq (20) can be linearized by introducing into the Lagrangian the source terms:

$$
\begin{equation*}
\eta_{d}\left(z_{d} \varphi_{1} \bar{c}+\bar{z}_{d}^{1} \bar{c}\right)+\eta_{2} z_{2} \varphi_{2} \bar{c} \tag{21}
\end{equation*}
$$

where $\eta_{1}, \eta_{2}$ are Fermi type sources:

$$
\begin{equation*}
S\left(z_{c}\right) \equiv \delta z_{c}=0 \tag{22}
\end{equation*}
$$

Now $Z_{C}$ also depends on $\eta_{1}, \eta_{2}$ whereas the Lagrangian is the partial Legendre transform of $Z_{c}$ with respect to $J_{1}, J_{2}, J_{\mu}, \xi, \xi$
$\mathcal{F}$ is now a linear functional partial differential operator of the form :

$$
\begin{align*}
\mathcal{J} & \int d x\left[J_{\mu} \partial_{\mu} \delta_{\xi}-e_{1} J_{1} \delta_{\eta_{2}}+e_{2} J_{2} \delta_{\eta_{1}}+m J_{2} \delta_{\xi}\right. \\
& \left.-\xi\left(a \partial_{\mu} \delta_{J_{\mu}}+\rho \delta_{J_{2}}\right)\right](x) \tag{23}
\end{align*}
$$

The transformation law (19) is easily converted by translation and renormalization of the field variables into the more conventional one

$$
\begin{align*}
& \delta \varphi_{1}=-\lambda \cdot e \varphi_{2} \bar{c} \\
& \delta \varphi_{2}=\lambda e\left(\varphi_{1}+v\right) \bar{c} \tag{24}
\end{align*}
$$

$$
\delta A_{\mu}=\lambda \partial_{\mu} \bar{e}
$$

$$
\delta c=\lambda\left(\partial_{\mu} A_{\mu}+\rho \varphi_{2}\right)
$$

( $e_{1}^{0}=e_{2}^{0}=e, v=v^{0}, \rho=\rho^{0}, a^{0}=1$ ), where we keep however a field translation parameter explicit.

One may ask oneself what is the most general Lagrangian of the renormalizable type which is invariant under such a transformation, even under charge conjugation and carrying zero $\phi \pi$ charge.
This problem is a purely algebraic one. The most general Lagrangian of the renormalizable type which carries the vacuum quantum numbers is, up to a divergence, a linear combination of the following twenty six monomials:

| 0) $\varphi_{1}$ | wi $\varphi_{2} \partial_{\mu} A_{\mu}$ |
| :--- | :--- |
| 1) $\varphi_{1}^{2}$ | 1) $A_{\mu} \varphi_{1} \partial_{\mu} \varphi_{2}$ |
| 2) $\varphi_{2}^{2}$ | ä $A_{\mu} \varphi_{2} \partial_{\mu} \varphi_{1}$ |
| 3) $\varphi_{1}^{3}$ | 13) $A_{\mu} A_{\mu}$ |
| 4) $\varphi_{2}^{2} \varphi_{1}$ | 14) $A_{\mu} A_{\mu} \varphi_{1}$ |
| 5) $\varphi_{1}^{4}$ | 15) $A_{\mu} A_{\mu}^{\mu} \varphi_{1}^{2}$ |
| 6) $\varphi_{2}^{4}$ | 16) $A_{\mu} A_{\mu} \varphi_{2}^{2}$ |
| 7) $\varphi_{1}^{2} \varphi_{2}^{2}$ | 17) $\left(\partial_{\mu} A_{\mu}\right)^{2}$ |
| 8) $\partial_{\mu} \varphi_{1} \partial_{\mu} \varphi_{1}$ | 1.8) $\left(\partial_{\mu} A_{\nu}-\partial_{\nu} A_{\mu}\right)\left(\partial_{\mu} A_{\nu}-\partial_{\mu} A_{\nu}\right)$ |
| 9) $\partial_{\mu} \varphi_{2} \partial_{\mu} \varphi_{2}$ | 19) $\left(A_{\mu} A_{\mu}\right)^{2}$ |

20) $\bar{c} c$
21) $\bar{c} \varphi, c$
22) $\bar{e} \varphi_{1}^{2} c$
23) $\bar{c} \varphi_{2}^{2} c$
24) $\bar{C} A_{\mu} A_{\mu} C$
25) $\bar{e} \square c$

Its variation $\delta \mathcal{L}$ under the Slavnov transformation (24) is of maximal dimension five, carrying the $\phi \pi$ charge of a $\bar{c}$ ghost, odd under charge conjugation. It is therefore a combination of the 23 monomials:
i) $\bar{c} \varphi_{2}$
11) $\bar{c} \partial_{\mu} A_{\mu}$
21) $\bar{c} A_{\mu} A_{\mu} \varphi_{2}$
2) $\bar{c} \varphi_{1} \varphi_{2}$
12) $\bar{c} A_{\mu} \partial_{\mu} \varphi_{1}$
3) $\bar{c} \varphi_{2}^{3}$
13) $\bar{c} \partial_{\mu} A_{\mu} \varphi_{1}$
4) $\bar{c} \varphi_{1}^{2} \varphi_{2}$
5) $\bar{c} \square \varphi_{2}$
14) $\bar{c} \partial_{\mu} A_{\mu} \varphi_{1}^{2}$
6) $\bar{e} \varphi_{1}^{3} \varphi_{2}^{2}$
15) $\bar{c} A_{\mu} \varphi_{1} \partial_{\mu} \varphi_{1}$
16) $e \partial_{\mu} A_{\mu} \varphi_{2}^{2}$
7) $\bar{c} \varphi_{1} \varphi_{2}^{3}$
17) $\bar{c} A_{\mu} \varphi_{2} \partial_{\mu} \varphi_{2}$
8) $\bar{c} \varphi_{2} \square \varphi_{1}$
18) $\bar{e} \bar{\square} \partial_{\mu} A_{\mu}$
9) $\bar{c} \varphi_{1} \square \varphi_{2}$
19) $\bar{e} A_{\mu} \partial_{\mu} \bar{e} e$
10; $\bar{e} \partial_{\mu} \varphi_{1} \partial_{\mu} \varphi_{2}$
$20) \bar{e} A_{\mu} A_{\nu} \partial_{\mu} A_{\nu}$

One can however verify that the last three monomials can never occur as variations of some monomials in $E_{q_{0}}(25)$ whereas the first twenty are such variations. It follows that the requirement that $\mathcal{L}$ be invariant under Slavnov transformations is expressed via a homogeneous linear system of twenty equations whose unknowns are the coefficients of the twenty six monomials listed in Eq(25) As a result, the most general invariant $\mathcal{L}$ can be written as a linear combination of the following six terms:
I) $G_{\mu \nu} G_{\mu \nu}=\left(\partial_{\mu} A_{\nu}-\partial_{\nu} A_{\mu}\right)\left(\partial_{\mu} A_{\nu}-\partial_{\nu} A_{\mu}\right)$
2) $\left(D_{\mu} \varphi\right)^{*} D_{\mu} \varphi$
3) $\varphi^{*} \varphi$
4) $\left(\varphi^{*} \varphi\right)^{2}$
5) $\frac{g^{2}}{2}+\bar{e} \frac{\delta g}{\delta \Lambda} c$
6) $\quad \frac{A_{\mu} A_{\mu}}{2}-\bar{c} c+\frac{\rho}{e} \varphi$
where

$$
\begin{array}{ll}
\varphi=\frac{\varphi_{1}+v+i \varphi_{2}}{\sqrt{2}} & g=\partial_{\mu} A_{\mu}+\rho \varphi_{2} \\
D_{\mu}=\partial_{\mu}-i e A_{\mu} & \frac{\delta g}{\delta \lambda}=\square+\rho e v+\rho e \varphi_{1}
\end{array}
$$

In other words, is of the form

$$
\begin{align*}
\mathscr{L} & =-\frac{z_{A}}{4} G_{\mu \nu} G_{\mu \nu}+Z_{\mu}\left(D_{\mu} \varphi\right)^{*} D_{\mu} \varphi+\mu^{2} \varphi^{*} \varphi \\
& -g\left(\varphi^{*} \varphi\right)^{2}-\frac{1}{\alpha}\left(\frac{g^{2}}{2}+\bar{c} \frac{\delta G}{\delta \Lambda} c\right)  \tag{29}\\
& +\beta\left(\frac{1}{2} A_{\mu} A_{\mu}-\bar{e} e+\frac{\rho}{e} \varphi_{\lambda}\right)
\end{align*}
$$

The last term which is conspicuously absent from the classical figs Kibble Lagrangian has precisely to do with the phenomenon previously alluded to. Its presence violates spontaneous breakdown without spoiling the Slavnov identity. As we shall see later, its absence can be imposed by requiring suitable normalization conditions on the Green functions which allow to convert the unphysical parameters $Z_{A}, Z_{l}, \mu^{2}, g, \alpha, \rho, \beta \quad$ into parameters that are needed to interpret the theory in terms of particles.

In terms of the variables appropriate to the case of broken symmetry, $\mathrm{F}_{\mathrm{q}}$ (29 )can rewritten as:

$$
\begin{align*}
& \mathcal{L}=-\frac{Z_{A}}{4} G_{\mu \nu} G_{\mu \nu}+Z_{1}\left[\partial_{\mu} \varphi_{1} \partial_{\mu} \varphi_{1}+\partial_{\mu} \varphi_{2} \partial_{\mu} \varphi_{2}\right. \\
& +2 e A_{\mu}\left(\varphi_{2} \partial_{\mu} \varphi_{1}-\left(\varphi_{1}+v\right) \partial_{\mu} \varphi_{2}\right)+e^{2} A_{\mu} A_{\mu}\left(\left(\varphi_{1}+v\right)^{2}\right.  \tag{30}\\
& \left.\left.+\varphi_{2}^{2}\right)\right]+\mu^{2}\left[\left(\varphi_{1}+v\right)^{2}+\varphi_{2}^{2}\right]-g\left[\left(\varphi_{1}+v\right)^{2}+\varphi_{2}^{2}\right]^{2} \\
& -Z_{\mu}\left[\frac{\left(\partial_{\mu} A_{\mu}+\rho \varphi_{2}\right)^{2}}{2}+\bar{e}\left(\square+\rho e\left(\varphi_{1}+v\right)\right) e\right] \\
& +\beta\left[\frac{A_{\mu} A_{\mu}}{2}-\bar{e} c+\frac{\rho}{e} \varphi_{1}\right]
\end{align*}
$$

We shall now impose the following normalization conditions, which for reasons to be explained, we split into two groups:

Unphysical :

$$
\begin{equation*}
\left\langle\varphi_{\lambda}\right\rangle=0 \tag{0}
\end{equation*}
$$

$$
\begin{equation*}
\Gamma_{c \bar{c}}\left(\hat{p}^{2}=m_{c}^{2}\right)=0 \tag{I}
\end{equation*}
$$

$$
\begin{equation*}
\Gamma_{c}^{\prime} \bar{c}\left(p^{2}=m_{a}^{2}\right)=\frac{l}{\alpha} \tag{2}
\end{equation*}
$$

Physical

Here $A^{\top}$ (reap $A^{2}$ ) denotes the transverse (resp .longitudinal part) of $A$; expressed in terms of the parameters specifying $\mathcal{L}$, these conditions read:

$$
\begin{align*}
& \left\langle\varphi_{1}\right\rangle=0=2 v \mu^{2}-4 v^{3} g+\frac{\rho \beta}{e}  \tag{0}\\
& m_{G}^{2}=\rho e v+\beta \alpha \tag{I}
\end{align*}
$$

$$
\begin{align*}
& \Gamma_{\varphi_{1} \varphi_{1}}\left(p^{2}=M^{2}\right)=0  \tag{3}\\
& \Gamma_{\varphi_{1} \varphi_{2}}^{\prime}\left(p^{2}=M^{2}\right)=\bar{t}_{\varphi_{1}}=1  \tag{4}\\
& \Gamma_{A^{\top} A_{A} T} T\left(p^{2}=m^{2}\right)=0  \tag{5}\\
& \Gamma_{A^{\top} A^{\top}}^{\prime}\left(P^{2}=m^{2}\right)=z_{A}=1 \tag{6}
\end{align*}
$$

$$
\begin{gather*}
Z_{a}=\frac{1}{\alpha}  \tag{2}\\
M^{2}=\frac{2}{Z_{1}}\left(6 g v^{2}-\mu^{2}\right)  \tag{3}\\
Z_{l}=Z_{\varphi_{1}}=1  \tag{4}\\
m^{2}=\left[Z_{1} e^{2} v^{2}+\beta\right] Z_{A}^{-1}  \tag{5}\\
Z_{A}=z_{A}=1  \tag{6}\\
e=\varepsilon  \tag{7}\\
\left.\Gamma_{e c}^{-1} \operatorname{det}\left(\begin{array}{ll}
\Gamma_{A^{L} A^{2}} & \Gamma_{A^{2} \varphi_{2}} \\
\Gamma_{A^{\prime} \varphi_{2}} & \Gamma_{\varphi_{2}} \varphi_{2}
\end{array}\right)\right|_{p^{2}=m_{a}^{2}}  \tag{32}\\
=-\left.\frac{1}{\alpha} \frac{1}{p^{2}-\rho e v-\beta \alpha}\left(\left(p^{2}-\rho e v-\beta \alpha\right)\left(p^{2}-\rho e v-\frac{\beta \rho}{l v}\right)\right)\right|_{p^{2}=m_{a}^{2}} ^{2} \\
=\beta\left(\frac{\rho}{e v}-\alpha\right)=0 \tag{8}
\end{gather*}
$$

This last normalization condition is well defined because the $\phi \pi$ ghost mass turns out to be degenerate with at least one of the coupled ( $A^{h}, \varphi_{2}$ ) ghost system. This is a consequence of the Slavnov identity, as shown in appendix III . On the other hand complete degeneracy of the ghost masses is precisely the condition for spontaneous breakdown, ( $\beta=0$ ), except if $\rho=\alpha \ell V$, which characterizes the restricted $t^{\prime}$ Hoof gauge, excluded here and eventually recovered by a limiting procedure The system is an algebraic system which is invertible and allows to solve for the coefficients in the Lagrangian in terms of the parameters occuring in the normalization conditions. This leads to a particle interpretation of the theory in a Pock space carrying an indefinite metric due to the Fermi character of the $\oint \pi$ ghosts and the non positive definiteness of the ( $A^{L}, \varphi_{2}$ ) coupled propagator matrix .

One can easily generalize this analysis to the case where $e_{1}^{0} \neq e_{2}^{0}$, $a^{0} \neq 1$ where the theory is again determined by the Slavnov identity and normalization conditions, $e_{2}^{0}$ and $Q^{0}$ being left free. Although the corresponding algebra is not illuminating and will not be reported here, the
possibility of such a generalization should be kept in mind for further reference .

We are now able to describe the scattering theory : the Fork space is determined by the quadratic part of $\mathcal{L}$, the corresponding in fields being solutions of the derived Euler Lagrange equations. Within this Fork space we may select a physical subspace generated from vacuum by application of ( $\varphi_{1 \text { in }} A_{i u n}^{\top}$ ). Physical states should actually be equivalence classes of such states modulo some zero norm states whose structure will be mentioned later in connection with the questions of the unitarity of the physical $S$ operator and of the existence of physical local observables.

The restriction to the above defined physical subspace of the connected scatter ring operator is given by the $L S Z$ formula :

$$
\begin{align*}
S_{\text {phys }}^{c}= & : \exp \left[i \int d x d y \left(\varphi_{1, \mu}(x) K_{1}(x, y) \frac{\delta}{\delta J_{1}(y)}\right.\right. \\
& \left.\left.+A_{\mu, i \mu}^{T}(x) K_{\mu \nu}(x, y) \frac{\delta}{\delta J_{\nu}(y)}\right)\right]:\left.Z^{c}[\underline{J}]\right|_{J_{\mu}=J_{1}=J_{2}=\bar{\xi}=\xi=0} \\
\equiv & \left.\sum_{\text {phys }} Z^{c}(\underline{J})\right|_{\underline{J}=0} \tag{33}
\end{align*}
$$

where, in view of $\operatorname{Eq}(3 I, 3,4,5,6)$

$$
\begin{align*}
& K_{1}(x, y)=\left(\square+M^{2}\right) S_{\mu}(x-y) \\
& K_{\mu}(x, y)=\left(\square g_{\mu \nu}-\partial_{\mu}+m^{2} g_{\nu \nu}\right)(x-y) \tag{34}
\end{align*}
$$

It is typical of the spontaneously broken theory that the physical scattering operator does not depend on the parameters which specify the gauge. In other words,

$$
\begin{equation*}
\frac{\partial S \text { phys }}{\partial \alpha}=0 \tag{35}
\end{equation*}
$$

The first relation can be proved as follows:

$$
\begin{align*}
\frac{\partial S_{p}^{c} \text { plays }}{\partial \rho} & =\left.\sum_{\text {ploys }} \frac{\partial Z^{c}[J]}{\partial \rho}\right|_{J=0}  \tag{36}\\
& =\left.\sum_{\text {plays }}\left(-\frac{1}{\alpha}\right) \int d x\left[g_{2}+\bar{e} e_{2}^{0}\left(\varphi_{1}+v^{0}\right) c\right](x)\right|_{J=0}=0
\end{align*}
$$

since the expectation value of $\mathcal{G}$ between physical states vanishes because of the Slavnov identity and those of $c$ and $\bar{c}$ because of $\phi \pi$ charge conservation Similarly.

$$
\begin{align*}
\frac{\partial S_{\text {phys }}^{C}}{\partial \alpha} & =\left.\sum_{\text {phys }} \frac{\partial Z^{C}[J]}{\partial \alpha}\right|_{J=0}  \tag{37}\\
& =\left.\sum_{\text {phys }} \frac{1}{\alpha^{2}} \int d x\left(\frac{g^{2}}{2}+\bar{c} m e\right)(x)\right|_{J=0} \\
& =\left.\sum_{\text {plays }} \frac{1}{\alpha^{2}} \int d x\left(\frac{g^{2}+\bar{c} m_{c}}{2}+\bar{\xi} e\right)(x)\right|_{J=0}=0
\end{align*}
$$

This concludes our review of the tree approximation.

## II PERTURBATION THEORY TO ALL ORDERS:- THE SLAVNOV IDENTITIES

The extension of the model beyond the tree approximation, proceeds in the spirit of the BPHZ (5) renormalization scheme, via an effective Lagrangian of the form

$$
\begin{align*}
& \left.\mathcal{L}_{(\underline{e f f}}^{\text {er }}, \underline{\underline{\eta}}, \underline{\eta}\right)=\mathcal{L}_{4}^{\text {eff }}(\underline{\varphi})+\eta_{1}\left(z_{1} N_{2}\left[\bar{c} \varphi_{1}\right]+z_{1}^{\prime} \bar{e}\right) \\
& +\eta_{2} z_{2} N_{2}\left[\bar{e} \varphi_{2}\right]+J_{1} \varphi_{1}+J_{2} \varphi_{2}+J_{\mu} A_{\mu} \\
& +\bar{\xi} c+\bar{\xi} \bar{e} \\
& =\mathcal{L}^{2 /( }(\underline{,}, \eta)+\underline{J} \underline{\varphi} \tag{38}
\end{align*}
$$

The corresponding Green functional

$$
\begin{equation*}
Z(\underline{J}, \underline{\eta})=\left\langle T \exp \left[\left[\frac{i}{\hbar} \iint_{i=4}^{\mu f}(\varphi, \underline{J}, \underline{\eta})(x) d^{4} x\right]\right\rangle\right. \tag{39}
\end{equation*}
$$

and

are expressed in terms of Feynman graphs in which the propagators are defined by the quadratic part $\mathcal{L}^{\circ}$ of $\mathcal{L}(\operatorname{Eqs},(30,31))$, and the vertices are given by

$$
\begin{equation*}
\mathcal{L}_{\text {ut }}^{\text {eff }}=\mathcal{L}^{\text {eft }}(\varphi, I, \eta)-N_{4} \mathcal{L}_{0} \tag{41}
\end{equation*}
$$

The substraction procedure which defines the time ordering symbol $T$ in
Eqs. $(39,40)$ being specified by the $N$ prescriptions indicated in Eq (38). The coefficients of the Wick monomials in $\mathcal{L}^{\ell A}$ are to be considered as formal power series in $\hbar$, and, of course, $\ell^{\text {价 }}$ should coincide in zeroth order with (Eqs.(31)).
We shall also clearly restrict ourselves to effective Lagrangian even under charge conjugation and carrying no $\oint \pi$ charge.
One can furthermore immediately specialize Eq d (38) by making the choice

$$
\begin{equation*}
z_{1}=z_{2}=1 \quad z_{1}^{\prime}=0 \tag{42}
\end{equation*}
$$

which corresponds to fixing normalization conditions on the fields coupled to fl, We can also define $\mathcal{L}^{e}(\underline{\varphi}(\underline{\varphi}$, so that no linear term is present, thus automat tidally fulfilling the porymization condition $(31,0)$

$$
\begin{equation*}
\left\langle\varphi_{1}\right\rangle=0 \tag{31,0}
\end{equation*}
$$

We shall have however to keep in mind in the following that the allowed class of Lagrangian is that written down in Eq (38) and $\mathscr{L}(\underline{\varphi})$ is a linear combination of 25 terms which are listed in Eq (25) (excluding Eq. $(25,0)$ in view of Eq. $(31,0)$
The question is now whether one can determine $\mathcal{L}^{\text {㫙 }}$ so that $Z^{e}(\underline{J}, \eta)$ fulfills a renormalized slavnov identity :

$$
\begin{align*}
\delta \nexists(J, \eta)= & \int d x\left[J_{\mu} \partial_{\mu} \delta_{\xi}-\bar{e} J_{1} \delta_{\eta}+\bar{e}_{2} J_{2} \delta_{\eta}+\bar{m} J_{2} \delta_{\xi}\right. \\
& \left.-\xi\left(\bar{a} \partial_{\mu} \delta_{J_{\mu}}+\bar{p} \delta_{J_{2}}\right)\right](x) Z^{c}(\bar{J}, \eta)=0 \tag{43}
\end{align*}
$$

where $\bar{a}, \bar{\rho}, \bar{e}_{1}, \bar{l}_{2}, \bar{m}=\bar{l}_{2} \bar{v} \quad{ }_{2}$ are formal power series in $t$ We shall eventually require that the normalization conditions (3) be fulfilled.

Now, according to Lam's
(7) renormalized action principle, the Slavnov identity (43) expresses the invariance of the effective Lagrangian under the renormalized Slavnov transformation

$$
\begin{align*}
& \delta \varphi_{1}=\lambda \bar{e}_{2} N\left[\varphi_{2} \bar{e}\right] \\
& \delta \varphi_{2}=\lambda\left(\bar{e}_{1} N_{2}\left[\varphi_{1} \bar{e}\right]-\bar{m} \bar{c}\right) \\
& \delta A_{\mu}=\lambda \partial_{\mu} \bar{e} \\
& \delta c=\lambda\left(\bar{a} \partial_{\mu} A_{\mu}+\bar{\rho} \varphi_{2}\right)  \tag{44}\\
& \delta \bar{c}=0
\end{align*}
$$

Indeed performing on an arbitrary effective Lagrangian the quantum variation (44) according to the quantum action principle yields:

$$
\begin{equation*}
\delta z^{c}(J, \eta)=\Delta z^{c}(J, \eta) \tag{45}
\end{equation*}
$$

where the left hand side comes from the variation of the source terms, and where - $\triangle$ is precisely the insertion of the quantum variation of the effective Lagrangian $\mathscr{L}(\underline{Y})$. It is a consequence of Lam's analysis that:

$$
\begin{equation*}
\Delta=-\int d x N_{5}\left[s \mathcal{L}^{2 f}(\varphi, \eta)+\hbar Q\right](x) \tag{46}
\end{equation*}
$$

where
 sums up the quantum corrections. Because of power counting and selection rules
$\triangle \quad$ is a linear combination of twenty three monomials listed in F . (26), the coefficients being formal power series in $\hbar$ and in the coefficients of $\mathcal{L}^{\text {eff }}$ as well as in those appearing in f(4/4). The symmetry condition we are looking for is

$$
\begin{equation*}
\Delta=0 \tag{47}
\end{equation*}
$$

It can be partially satisfied by requiring that the coefficients of the 20 first monomials vanish to all orders in $t$ the parameters of the Slavnov identity being left arbitrary to all orders. The argument is that if

$$
\begin{equation*}
\mathcal{L}^{\text {eff }}=c_{G} \underline{\mathcal{L}}^{b}+c_{b} \underline{Z}^{b} \tag{48}
\end{equation*}
$$

where: $\quad s \underline{\mathscr{L}}^{h}=0, \quad s \underline{\mathscr{L}}^{b} \neq 0$
we can write:

$$
\begin{equation*}
\Delta=\underline{d}_{b} \delta \mathscr{A}^{b}+\hbar R \tag{50}
\end{equation*}
$$

where $\quad d_{b}=c b+\Phi_{b} \sum_{b} \quad \Phi_{b} \quad$ being a formal power series in $t, C_{4}, C_{b} \quad$ and the coefficients $\delta$ of the slavnov identity, and the quantum correction $\frac{1}{\mathcal{R}}$ is not of the form $\& \mathcal{L}^{b}$, namely it involves the last three monomials in Eq. (26). By the implicit function theorem for formal power series, (cf. Appendix II) the system:

$$
\subseteq_{b}+t \Phi_{b}\left(h, \subseteq_{b}, \subseteq_{b}, 1\right)=0
$$

is soluble for $C_{b}$
$\mathcal{L}^{\text {eft }}$ is thus now determined in terms of five parameters (because of $(31,0)$ ) and of the five coefficients involved in the Slavnov identity which now reads

$$
\delta Z^{e}(J, \eta)=\left(e_{1} \Delta_{1}+c_{2} \Delta_{2}+c_{3} \Delta_{3}\right) Z^{c}(J, \eta)_{(52)}
$$

where $\Delta_{1}, \Delta_{2}, \Delta_{3} \quad$ (previously numbered 21, 22, 23) are the last three terms in (26), affected with the $N_{5}$ prescription.
Now, obviously, the right hand side (52) has to fulfill the compatibility condition implied by the structure of the left hand side (cfEqs $(12,13)$ namely:

$$
\begin{align*}
\delta^{2} z & \equiv-\int d x\left[\xi\left((\bar{a} \square+\bar{\rho} \bar{m}) \delta_{\xi}+\bar{p} \bar{e}_{2} \delta_{\eta}\right)\right](x) z^{c} \\
& \equiv-\int d x\left[\xi_{1}\left(\bar{m} \delta_{\xi}\right)\right](x) z^{c}  \tag{53}\\
& =\delta\left(c_{1} \Delta_{1}+c_{2} \Delta_{2}+c_{3} \Delta_{3}\right) z^{c} \\
& =\left[\delta, c_{1} \Delta_{1}+c_{2} \Delta_{2}+c_{3} \Delta_{3}\right] z^{c}
\end{align*}
$$

Now,$\left[8, \Delta_{i}\right] Z^{c}=\left[s \Delta_{i}+\hbar P_{i}\right] Z^{c}$
where $\Delta \Delta_{i}$ is the naive variation of the monomial $\Delta_{i}$ under a Slavnov transformation, to which dimension six is assigned, whereas $P_{i}$ is a dimension six insertion, carrying two charges, even under charge conjugation and whose coefficients are formal power series in $t_{\text {af }}$ and in the so far undetermined power series coefficients occuring in $\mathcal{L}$ and $\&$, as a consequence of Zimmermann's reduction formulae.
On the other hand, the $\phi \pi$ ghost equation of motion is of the form :

$$
\stackrel{\rightharpoonup}{\bar{\varphi}}=\left\{N_{3}\left[\varphi_{1}^{2} \bar{e}\right], N_{3}\left[\varphi_{2}^{2} \bar{e}\right], N_{3}\left[A_{1} A_{,}, \bar{e}\right]\right\}
$$

Thus, integrating Eq.(52)through $\bar{\xi}$, one gets

$$
\begin{equation*}
\int d x\left[\bar{\xi}\left(\bar{n} \delta_{\xi}\right)\right](x) \not z^{e}=0 \tag{56}
\end{equation*}
$$

Noticing that

$$
\begin{equation*}
\int d x\left(\bar{\xi} \delta_{\xi}\right)(x) z^{c}=0 \tag{57}
\end{equation*}
$$

as a consequence of the invariance of $\mathscr{L}(\Phi, \xi)$ under the variation

$$
\delta e=\lambda \bar{c}
$$

and substracting Eq.(56) from Eq. (53) yields:

$$
\begin{align*}
& \left.\int d x\left[\bar{\xi}\left(\left(\vec{\rho} \bar{e}_{2}-d\right) \xi_{\beta_{1}}-\vec{f} \cdot \delta_{\vec{\beta}}\right)\right](x) \underset{Z}{C}(\underline{J}, \underline{\beta})\right|_{\vec{\beta}=0} \\
& =\sum_{i}^{3} e_{i}\left(\delta \Delta_{i}+\frac{\hbar}{\hbar} P_{i}\right) \not Z^{C}(\underline{J}, \Omega) \tag{58}
\end{align*}
$$

We now express $\mathcal{Z}^{c}$ in terms of $\Gamma$ by Legendre transform, thus obtaining:

$$
\begin{align*}
& \int d x\left[\left(d-\overline{\rho a_{2}}\right) \delta_{e} \Gamma \delta_{\eta}^{1} \Gamma+\left.\vec{p} \delta_{e} \Gamma \delta_{\beta}[](x)\right|_{\vec{\beta}=0}\right. \\
& =\sum_{1}^{3} e_{i}\left(s \Delta_{i}+t_{1} \rho_{i}\right) \Gamma=\left.0\right|_{\vec{\beta}=0} \tag{59}
\end{align*}
$$

Let us now write

$$
\begin{equation*}
\Gamma=\rho^{\prime f}(\underline{J}, \underline{r})+\vec{\beta} \cdot \overrightarrow{\vec{e}}+t \Gamma^{\prime} \tag{60}
\end{equation*}
$$

where it has been explicitly noted that the corrections to $\mathcal{f}$ occuring in $\Gamma$ are necessarily radiative corrections. Eq (59) can be cast into the form:

$$
\begin{align*}
\int d x\{\square \bar{e} & {\left[\left(d-\overline{\rho e_{2}}\right) \varphi_{1} \bar{e}+f_{1} \varphi_{1}^{2} \bar{e}+f_{2} \varphi_{2}^{2} \bar{e}+f_{3} A_{\mu} A_{\mu} \bar{e}\right.} \\
& +2 c_{1} \bar{e} A_{\mu} \partial_{\mu} \bar{c} \varphi_{2}+2 e_{2} A_{\mu} \partial_{\mu} \bar{c} \varphi_{1} \varphi_{2} \\
& \left.+e_{3}\left(2 \bar{e} \partial_{\mu} \bar{c} A_{\mu} \partial_{\nu} A_{\nu}+\bar{e} A_{\mu} A_{\mu} \square \bar{c}\right)\right](x) \\
= & \frac{1}{h} \phi\left(d-\bar{\rho} e_{2}, f_{1}, f_{2}, f_{3}, e_{1}, c_{2}, e_{3}\right) \tag{61}
\end{align*}
$$

where $b$ is a functional of the fields which is linear in the indicated arguments and lumps together contributions from $\Gamma^{\prime}$ and from the $P_{i}^{\prime} \delta$. Differentiating in turn $G_{q}$ ( $6 y$ ) with respects to the fields occuring in each indicated monomial, and setting all fields equal to zero, yields, in view of the independence of these monomials:

$$
\begin{align*}
& d-\bar{\rho} \bar{e}_{2}=\frac{t}{p}\left(d-\bar{\rho} \cdot \bar{e}_{2}, f, e\right) \\
& f_{1}=t_{1} \phi_{1}\left(d-\bar{\rho} \bar{q}_{2}, f, E\right) \\
& f_{2}=t \phi_{2}\left(d-\bar{\rho}_{e_{2}}, f, c\right) \\
& f_{3}=t h \phi_{3}\left(d-\bar{\rho} \bar{e}_{2}, f, e\right)  \tag{62}\\
& c_{1}=\hbar \psi_{1}\left(\alpha-\overline{\rho e_{2}}, f, c\right) \\
& c_{2}=t h \psi_{2}\left(d-\bar{s} \bar{e}_{2}, f, c\right) \\
& c_{3}=t \psi_{3}\left(d-\bar{\rho} \bar{e}_{2}, f, e\right)
\end{align*}
$$

where

$$
\oplus_{i}(i=1,2,3), \psi_{i}(i=1,2,3) \text { are linear in the indicated }
$$ arguments, formal power series in $t \frac{t}{t}$ and in the remaining parameters. The situation occuring in the tree approximation and application of the theorem in appendix II yield:

$$
\begin{equation*}
d-\bar{\rho} \bar{e}_{2}=e_{1}=c_{2}=e_{3}=f_{1}=f_{2}=f_{3}=0 \tag{63}
\end{equation*}
$$

Hence, the Slavnov identity holds, and, up to the mass term the ${ }^{0}$ equation of motion involves the same coefficients and monomials as those occuring in $\delta^{2}$. The equality of the two mass terms will be proved in appendix III in connection with the normalization conditions we shall now consider .

Namely, we shall show that the normalization conditions (3) can be fulfilled, whereby all parameters are determined except $\bar{Q}$ and $\overline{e_{2}} \mathrm{Ea}(37,0)$ is already fulfilled. Next we try to impose $\operatorname{Eq}(34,1,2,3,4,5,6,7$ ) Looking at the algebraic system which is soluble in the tree approximation, we can apply once more the theorem of appendix II, because this system is perturbed as allowed by this theorem by higher order terms occuring in $\Gamma_{\varphi} \varphi_{1}, \Gamma^{\top} A^{\top} A^{\top}, \Gamma_{c} \bar{c}, \Gamma_{A^{\top} A^{\top} \varphi_{1}}$

The last normalization condition $(31,8)$ is more delicate : one has
 at $\quad p^{2}=M_{4}^{2}$. The proof, based on the Slavnov identity and Eq (31,2) is given in appendix III. As a by product, as previously announced, one obtains the last equation connecting $S^{2}$ and the $\phi \pi$ equation of motion (Eq, (52)) namely the $\#$ equation reads:

$$
\begin{equation*}
\left(\bar{M} \delta_{\xi}\right)(x) z^{e} \equiv\left(\bar{m} \delta_{\varepsilon}\right)(x) z^{e}=\bar{\xi}(x) \tag{64}
\end{equation*}
$$

In conclusion, once the Slavnov identities and the normalization conditions have been fulfilled, there remain two free parameters, $\overline{\mathbb{Q}}$ and $\overline{e_{2}}$, which will not be specialized any further.

The normalization conditions Eq. (3J) allow to interpret the theory, in the sense of formal power series, within the Fork space defined in the tree approximation, and the formula giving $S^{c}$ plays in terms of $Z^{C}(J)$ (Eq.31)) or similarly $S_{\text {plays }}$ in terms of $Z(J)$ remains unchanged For a technical reason which will appear later we shall from now on work with the non connected Green functional .
We now wish to evaluate

Using Lowenstein's

$$
\begin{aligned}
& \frac{\partial S_{\text {phys }}}{(6)} \frac{\partial S_{\text {renormalized action pr }}^{\partial \rho}}{\partial \alpha}
\end{aligned}
$$

$$
\begin{equation*}
\frac{\hbar}{i} \frac{\partial}{\partial \lambda} Z(\underline{J}, \underline{n})=\Delta_{\lambda} Z(\underline{J}, \underline{\eta}) \tag{65}
\end{equation*}
$$

where $\lambda$ is one of the parameters $\alpha, m^{2}$ and $\Delta_{\lambda}$ is a dimension four insertion obtained by differentiating $\mathcal{L}^{2 / 4}(\underline{\varphi}, \eta)$ with respect to $\lambda$, namely an operation which alters infinitesimally $\mathcal{L}(\underline{\varphi}, \underline{\eta})$ within the class (38) Using the Slavnov identity, we are going to show that $\Delta_{\lambda}$ can be written as

$$
\begin{equation*}
\Delta_{\lambda}=\sum_{1}^{8} c_{\lambda}^{0, i} \Delta_{i}^{0}+\sum_{i}^{6} c_{\lambda}^{5 i} \Delta_{i}^{5} \tag{66}
\end{equation*}
$$

where the $\Delta_{i}^{0}$ \& $(i=1, ., 8)$ are eight insertions such that

$$
\begin{equation*}
\left.\sum_{\text {phys }} \Delta_{i}^{0} Z(\underline{J}, \eta)\right|_{\underline{J}=\eta=0}=0 \tag{67}
\end{equation*}
$$

and leaving unchanged the physical normalization condition (31,8)
The other physical normalization conditions (31 $3,4,5,6,7$ ) are left unaltered as a consequence of Eq. (67). In the following, we shall call these insertions non physical The $\Delta_{i}^{S},(i=1 \ldots . . .6)$, are six symmetric insertions, namely such that

$$
\begin{equation*}
\delta \Delta_{i}^{S} z(\underline{J}, \underline{z})=0 \quad(i=1, \ldots, 6) \tag{68}
\end{equation*}
$$

Thus applying Eg (65) to the physical normalization conditions ( $31,3,4,5,6,7,8$ ) yields a linear homogeneous system of equations of the form

$$
\begin{equation*}
\sum_{i}^{6} C_{\lambda}^{s, i} \Delta_{i}^{S, j}=0 \quad(j=3,4,5,6,7,8) \tag{69}
\end{equation*}
$$

The forthcoming analysis shows that

$$
\begin{equation*}
\operatorname{det}\left\|\Delta_{i}^{S, j}\right\| \neq 0 \tag{70}
\end{equation*}
$$

since this happens to be true in the tree approximation. Hence it follows that

$$
e_{\lambda}^{5 i}=0
$$

and the gauge invariance of the physical S-operator follows from Eq (67)
We now construct the decomposition of $\Delta_{\lambda}$ given in Eq. (67)
From the definition of $\Delta \lambda$ we have

$$
\partial_{\lambda}(f z)=\partial_{\lambda} \& z+\frac{i}{\hbar} \& \Delta_{\lambda} z=0
$$

so that

Thus we can write

$$
\begin{equation*}
\frac{i}{\hbar}\left[\lambda_{\lambda}, 8\right]=\partial_{\lambda} 8 \tag{73}
\end{equation*}
$$

$$
\begin{equation*}
\Delta_{A}=\hat{\Delta}_{\lambda}+\hat{\Delta}_{\lambda}^{S} \tag{74}
\end{equation*}
$$

where $\hat{\Delta}_{\lambda}$ is a particular solution of Eq. $\Delta_{\lambda}=\Delta 3$ and $\Delta_{\lambda}^{S}$ is a symmetrical insertion We shall first construct a non physical $\hat{\Delta}_{\lambda}$, and we shall show that any $\Delta_{\lambda}^{\mathcal{S}}$ is a linear combination of nine symmetrical insertions three of which are non physical the remaining six satisfying Eq. (68)
Let us denote

$$
\begin{equation*}
\delta=\sum_{0}^{5} i c_{i} s_{i} \tag{75}
\end{equation*}
$$

where

$$
\begin{array}{ll}
c_{0}=1 & \delta_{0}=\int d x\left(J_{\mu} \partial_{\mu} \delta_{\xi}\right)(x) \\
c_{1}=-\bar{e}_{1} & \delta_{1}=\int d x\left(J_{1} \delta_{\eta}\right)(x) \\
c_{2}=\bar{e}_{2} & \delta_{2}=\int d x\left(J_{2} \delta_{\eta}\right)(x) \\
c_{3}=m & \delta_{3}=\int d x\left(\bar{J}_{2} \delta_{\xi}\right)(x)  \tag{76}\\
c_{4}=-\bar{a} & \delta_{4}=\int d x\left(\xi_{\xi} \partial_{\mu} \delta_{J_{\mu}}\right)(x) \\
c_{5}=-\bar{\rho} & \delta_{5}=\int d x\left(\xi \delta_{\bar{\xi}}\right)(x)
\end{array}
$$

So that Eq (73)

$$
\begin{equation*}
\frac{i^{\text {now }}}{\hbar}\left[\hat{\Delta}_{\lambda}, \delta\right]=\sum_{l}^{5} i \partial_{\lambda} c_{i} \delta_{i} \tag{77}
\end{equation*}
$$

Now, there exists a basis of covariant non physical insertions $\Delta_{1}$ : ( $i^{-1}, \ldots .5$ ) satisfying :

$$
\frac{i}{\hbar}\left[\Delta_{i}, S\right]=\lambda_{i}
$$

Rated let us consider:

$$
\begin{equation*}
Q_{i, \varepsilon}=\frac{\hbar e:}{2} \int^{2} d x\left(\delta_{g_{i}(\varepsilon)} \delta_{\xi(-\varepsilon)}\right)(x) \quad(i=4,5) \tag{78}
\end{equation*}
$$

where the $c_{i} \mathcal{1}$ are defined in Eq(76) and $\bar{\alpha}$ in Eq. (55)
The symbols $\delta_{g_{i}}$ are defined by:

$$
\begin{align*}
& \delta_{g_{4}}=\partial_{\mu} \delta_{J}  \tag{79}\\
& \delta_{g_{5}}=\delta_{J_{2}}
\end{align*}
$$

The indices $( \pm \varepsilon)$ indicate translations by the egg. space like small vectors $\pm \Sigma \quad$ 。

We introduce the insertions:

$$
\begin{equation*}
\Delta_{i, \varepsilon} Z=\delta Q_{i, \varepsilon} Z=\left[\delta, Q_{i, \varepsilon}\right] Z \tag{80}
\end{equation*}
$$

and we have :

$$
\text { where the connection between } \delta^{2} \text { and the } \phi \pi \text { equation of motion (Eq. } 64 \text { ) has }
$$ been used.

It is shown in Appendix $I V$ that, in the limit $s \rightarrow 0$ the finite part $\Delta_{i}$ of $\Delta_{i, \varepsilon}$ has the same covariance as $\Delta_{i, \varepsilon}$, namely

$$
c_{i} f_{i} Z(J, M)=\lim _{\varepsilon \rightarrow 0} e_{i} \int d x\left[\xi(-\varepsilon) \delta_{g_{( }(\varepsilon)}\right](x) \nexists(J, \eta)(82)
$$

It is furthermore shown, in appendix IV, that by substracting a symmetric insertion, which therefore does not alter the covariance $C_{i} \lambda_{i}$, one obtains non physical insertions which we denote $\Delta_{i}^{0}$.

$$
\begin{aligned}
& \frac{i}{\hbar}\left[\Delta_{i, \varepsilon,} \delta\right] \neq-\frac{i}{\hbar}\left[\&, Q_{i, \varepsilon}\right] Z \\
& =-\frac{i}{\hbar}\left[Q_{i, \varepsilon}, \int d x\left[\xi\left(\bar{m} \rho_{\xi}\right)\right](x)=\frac{\hbar}{i} \frac{c_{i}}{\overline{2}} \int d x\left[\delta_{g_{(\varepsilon)}}\left(\bar{M} \bar{M}_{\xi}\right)(-\varepsilon)\right](x)=c_{i} \int d x\left[\xi(-\varepsilon) \int_{g_{(\varepsilon)}}\right](x)\right.
\end{aligned}
$$

We now look for other non physical insertions which are easily obtained by applying the renormalized action principle (6)
The following variations whose covariances are indicated provide us with the desired insertions :
I) $\delta c \alpha c$ yields the insertion

$$
\begin{equation*}
A_{c}=\frac{t}{i} \int d x\left(\xi \delta_{\bar{\Sigma}}\right)(x) \tag{83}
\end{equation*}
$$

with

$$
\begin{equation*}
\frac{i}{\hbar}\left[\Delta_{c,}, f\right]=c_{4} \lambda_{4}+c_{5} \lambda_{5} \tag{84}
\end{equation*}
$$

2) the operation

$$
\begin{equation*}
\Delta_{\eta_{1}}=\frac{\hbar}{i} \int d x\left(\eta, \delta_{\eta_{1}}\right)(x) \tag{85}
\end{equation*}
$$

corresponds to a variation of $\sum_{1}$ in the neighbourhood of $z_{1}=z_{2}=1, z_{1}^{\prime}=0$ and its covariance is given by

$$
\begin{equation*}
\frac{i}{\hbar}\left[\Delta_{\eta_{1}}, \delta\right]=-c_{2} \delta_{2} \tag{86}
\end{equation*}
$$

3) the operation

$$
\begin{equation*}
\Delta_{\eta_{2}}=\frac{+}{i} \int \Delta x\left(\eta_{2} \delta_{\eta_{2}}\right)(x) \tag{87}
\end{equation*}
$$

corresponds to a variation of $z_{2}$. Its covariance is given by

$$
\begin{equation*}
\frac{i}{\hbar}\left[\Delta_{\eta_{2}}, \partial\right]=-c_{1} \lambda_{1} \tag{88}
\end{equation*}
$$

4) the operation

$$
\begin{equation*}
\Delta_{q_{1}}^{\prime}=\frac{\hbar}{i} \int d x\left(\eta_{1} \delta_{\xi}\right)(x) \tag{89}
\end{equation*}
$$

corresponds to a variation of " $z_{1}^{\prime}$. Its covariance is given by

$$
\begin{equation*}
\frac{i}{\hbar}\left[\Delta_{\eta_{1}}^{\prime}, \delta\right]=-c_{2} s_{3} \tag{90}
\end{equation*}
$$

It is obvious that all of these four insertions leave all physical normalizaLion conditions ( $31,3,4,5,6,7,8$ ) unchanged,
$\hat{\Delta}_{\lambda}$ is thus a linear combination of $\Delta_{4}^{0}, \Delta_{5}^{0}, \Delta_{\eta_{1}}, \Delta_{q_{2}}, \Delta_{q_{1}}^{1}$ which solves part of Eq d74)

We are thus left with finding a basis of symmetrical insertions.

We know that, given the slavnov identity $\mathscr{L}(\varphi, \eta)$ depends on nine parameters, namely six to specify $\mathcal{L}(\varphi)$, three to specify the external field dependence (i.e. $z_{1}, z_{2}, z_{1}^{1}$ ).
This is indeed true in the tree approximation and therefore, by the theorem of appendix II, to all orders. (of course, this counting does not take into account any of the normalization conditions (31), including (31, 0) ). As a consequence, there are nine independent symmetric insertions
We first construct those which respect the physical normalization conditions : The first one is :

$$
\begin{equation*}
\Delta_{0}^{0,5}=\Delta_{4}^{0}+\Delta_{5}^{0}-\Delta_{e} \tag{91}
\end{equation*}
$$

The second one is generated by the variation $\delta \varphi_{1}=$ coast.

$$
\begin{equation*}
\Delta_{1}^{0,5}=\int J_{1}(x) d x \tag{92}
\end{equation*}
$$

The third one is obtained by considering

$$
\begin{equation*}
\Delta \varphi_{2}=\frac{\hbar}{i} \int d x\left(J_{2} \delta_{J_{2}}\right)(x) \tag{93}
\end{equation*}
$$

whose covariance is given by

$$
\begin{equation*}
\frac{i}{\hbar}\left[\Delta \varphi_{2}, f\right]=c_{2} \lambda_{2}+c_{3} s_{3}-c_{5} s_{5} \tag{94}
\end{equation*}
$$

From the foregoing analysis:

$$
\begin{equation*}
\Delta_{2}^{0,5}=\Delta_{\varphi_{2}}+\Delta_{q_{1}}+\frac{c_{3}}{c_{2}} \Delta_{q_{1}}^{1}+\Delta_{5}^{0} \tag{95}
\end{equation*}
$$

is symmetric, leaves the physical normalization conditions unchanged, and is non zero as can be seen by a direct calculation at the tree level

We are thus left with finding six independent symmetric insertions By the general theorem of appendix II, five of them are determined by the terms of $\mathscr{L}$ (excluding the one which leads to $\Delta_{0}^{\infty}$, , The sixth one involves

$$
\begin{equation*}
\Delta_{A}=\frac{t}{i} \int d x\left(J_{\mu} \delta_{J_{\mu}}\right)(x) \tag{96}
\end{equation*}
$$

since

$$
\begin{equation*}
\frac{i}{\hbar}\left[\Delta_{A,} \delta\right]=C_{0}-\partial_{0}-C_{4} \delta_{4}=-C_{i} \partial_{1}-C_{2} \delta_{2}-C_{3} \partial_{3}-2 C_{4} J_{4}-C_{5} \partial_{5} \tag{97}
\end{equation*}
$$

it follows that

$$
\begin{equation*}
\Delta_{6}^{S}=\Delta_{A}-\Delta_{\eta_{2}}-\Delta_{\eta_{1}}-\frac{c_{3}}{c_{2}} \Delta_{\eta_{1}}^{1}+2 \Delta_{c}-\Delta_{5}^{0} \tag{98}
\end{equation*}
$$

is symmetric.

It is straightforward but tedious to verify in the tree approximation that these six insertions alter independently the six physical normalization conditions ( $31,3,4,5,6,7,8$ ).
The gauge invariance proof is thus completed. It is extended in appendix VII to gauges which contain a quadratic term odd under charge conjugation

## IV - UNITARITY OF THE S OPERATOR

Let us first define

$$
\begin{equation*}
S_{\text {phys }}(J)=\sum_{p_{p l y s}} \not Z(I) \tag{99}
\end{equation*}
$$

where the notations are the same as in Eq.(33). According to the reduction formula, the physical $S$ operator is given by

$$
\begin{equation*}
S_{p_{\text {bes }}}=\left.\int_{p_{b \text { bes }}}(J)\right|_{J=0} \tag{100}
\end{equation*}
$$

The contribution of non physical particle states to physical unitarity is explicitly given in the expression :

$$
\begin{align*}
& \equiv \int_{\text {phys }}^{+}(J) \text { exp }\left.A 0 \int_{\text {phys }}^{-}(J)\right|_{J=0} \tag{101}
\end{align*}
$$

Here $L$ and itu $S_{+}$are respectively the differential operator occuring in the asymptotic field equations and the positive frequency part of the asymptotic field commutator.

The proof consists in considering
and evaluating

$$
\begin{equation*}
\left.\partial_{\lambda} S_{\text {plays }}^{+}(J) u(\lambda) S_{\text {hus }}(J)\right|_{J=0} \tag{103}
\end{equation*}
$$

It is shown in appendix $V$, by extensive use of the Slavnov identity that

$$
\begin{aligned}
& \left.\partial_{\lambda} S_{p h y_{s}}^{+}(J) u(\lambda) S_{\text {phys }}(J)\right|_{J=0}=
\end{aligned}
$$

where

$$
\begin{equation*}
\delta_{J(g)}=\bar{a} \partial_{,} \delta_{J_{\mu}}+\bar{\rho} \delta_{J_{2}} \tag{105}
\end{equation*}
$$

index $g \mathcal{G}$ labels the "gauge-gauge", matrix element of $\mathbb{L} S_{+}^{\varepsilon} \vec{L}$ indicated in appendix $V$.
Integrating Eq. (104) with respect to $\lambda$ yields

Further use of the Slavnov identity according to which, the gauge operator decouples from physical states finishes the proof:

$$
\begin{align*}
& \left.S_{\text {jugs }}^{+}(J) u(1) S_{\text {phys }}(J)\right|_{J=0}=\left.S_{\text {plus }}^{+}(J) S_{j \text { buys }}^{S}(J)\right|_{J=0} \\
& =S_{\text {phys }}^{+} S_{\text {phys }} . \tag{107}
\end{align*}
$$

Unitarity follows from the hermiticity of the Lagrangian

The gauge invariance problem has been solved for the abelian Higgs Kibble model treated in a family of gauges odd under charge conjugation Emphasis was put on the fulfillment of normalization conditions which allow the interpretation of the theory within a Fock space with indefinite metric , This has in particular allowed us to prove the unitarity of the physical scattering operator and to construct some physical local observables, We feel however that one should make a more complete study of the zero norm states that are allowed in the definition of physical states as equivalence classes. From the technical point of view, it was encouraging to see that the theory was widely controlled by the algebraic structure of its tree approximation thanks to the repeated application of the implicit function theorem for formal power series. This situation looks quite favorable to a future treatement of the non abelian situations, at least when no fermion anomalies are potentially present. This last case will doubtlessly call for more refined techniques, involving the Callan-Symanzik equations which have not been included here.

## ACKNOWLEDGMENTS

We wish to thank M. Bergere, M. Gomes, Y-M. P. Lam,
J.H. Lowenstein, B. Schroer, M. Weinstein, W. Zimmermann, for keeping us informed of their current work, and for illuminating discussions, H. Kluberg-Stern and R. Seiler for constructive remarks.

## APPENDIX I : NON ABELIAN GAUGE TRANSFORMATIONS: CLASSICAL THEORY

Here are a few details concerning the classical theory of non abelian gauge transformations: the gauge parameters $\Lambda$ as well as the $\phi \pi$ ghost field $\overline{\mathcal{C}}$ are labelled by the indices of the dual of a Lie algebra $\mathcal{F}$ with structure constants $f$. The $\phi \mathbb{\|}$ ghost field $C$ and the gauge function $g$ are labelled by the Lie algebra itself. $M=\frac{\delta g}{\delta \wedge}$ is labelled as a linear operator from $\mathcal{F}$ into $\mathcal{F}$. The square of $\hat{g}$ is the killing form of $\mathcal{F}$ at least for the non degenerate part.
Going from the Ward identity to the Slavnov identity now involves an extra term:

$$
\begin{equation*}
-\int d x d y d z c_{\alpha}^{(x)}\left(\frac{\delta^{2} g_{\alpha}(x)}{\delta \Lambda_{(z)}^{\gamma} \delta \Lambda_{(y)}^{\beta}}\right) \bar{c}_{(z)}^{\gamma} c^{\beta}(y) \tag{AI,I}
\end{equation*}
$$

which, using the group law together with the anticommutativity of C boils down to

$$
\begin{equation*}
-\frac{1}{2} \int d x d y e_{\alpha}(x) \frac{\delta \mathcal{G}_{\alpha}^{(x)}}{\delta \Lambda_{(y)}^{\delta}} f_{\beta \gamma}^{\delta} \vec{c}_{(y) c}^{\gamma}-\varepsilon_{(y)}^{\beta} \tag{AI,2}
\end{equation*}
$$

or , using the equation of motion:

$$
\begin{equation*}
\frac{1}{2} \int d x \bar{c}^{\alpha}(x) f_{\alpha \beta}^{\gamma} \bar{c}^{\beta}(x) \xi_{\gamma}(x) \tag{AI,3}
\end{equation*}
$$

The corresponding Slavnov identity can then be interpreted as expressing the invariance of the lagrangian under the transformation law:

$$
\begin{gathered}
\delta \varphi_{i}(x)=\lambda \int d g \frac{\delta \varphi_{i}(x)}{\delta \Lambda^{\alpha}(y)} \bar{c}^{\alpha}(y) \\
\delta c_{\alpha}(x)=\lambda g_{\alpha}(x) \quad \delta \bar{e}^{-\alpha}(x)=\frac{\lambda}{2} f_{\beta \gamma}^{\alpha} \bar{c}^{\beta}(x) \bar{c}^{\gamma}(x)
\end{gathered}
$$

where $\lambda$ is a space time independent a.icicommuting parameter carrying no index

This appendix is devoted to the statement and proof of an easy theorem (11) which has been repeatedly used to reduce the proof of a property to all orders of perturbation theory down to the verification of a simple algebraic property of the tree approximation :
TH Let $F_{i}\left(x_{1}, \ldots, X_{n} ; y_{1}, \ldots, y_{p}\right)=0(i=1, ., n)$ be a set of algebraic analytic equations which has a unique solution $x_{i}=\varphi_{i}\left(y_{1}, \ldots, y_{p}\right)$ (analytic) in $\left(y_{1}, \ldots, y_{p}\right)$ in some neighbourhood of $\left(y_{1}^{0}, \ldots, y_{p}^{0}\right)$.

Then the perturbed system

$$
F_{i}\left(\underline{x}_{1}, \ldots, \underline{x}_{n} ; \underline{y}_{1}, \ldots, y_{p}\right)=\hbar f_{i}\left(\underline{x}_{1}, \ldots, x_{n} ; \underline{y}_{1}, \cdots, y_{p} ; \hbar\right) \quad(i=1, \ldots, n)
$$

where $\mathscr{g}_{l, \cdots, y_{p}}$ are formal power series in $t$ whose lower order terms are
$\mathscr{H}_{l}^{0}, \ldots y_{p}$ and the $f_{i} s$ are formal power series in $x_{l}, \ldots, x_{4}, y_{1}, \ldots, y_{p}, t$,

$$
x_{i}=\varphi_{i}\left(t, \underline{y}_{1}, \cdots, y_{p}\right)
$$

where the $\underline{\varphi}_{i}^{\prime} \delta$ are formal power series in $t, y_{1}, \ldots, y_{p}$

Proof:

$$
\text { Let } \quad \xi_{i}=\underline{x}_{i}-\varphi_{i}\left(\underline{y}_{1}, \cdot \cdot, \underline{y}_{p}\right)
$$

$F_{i}$ can be expanded into a formal power series in $\xi_{i}, y_{i}$, whose term linear in $\sum \quad$ is

$$
\left.\frac{\partial F_{i}}{\partial x_{j}}\right|_{\xi_{j}} ^{\xi_{j}} \varphi_{k}\left(\varphi_{1}, \cdots, \varphi_{p}\right)
$$

where, by the hypothesis $\operatorname{det}\left\|\frac{\partial F_{i}}{\partial x_{i}}\right\|$
is invertible in the sense of formal power series. Hence the initial system can be cast into the form
$\left.\frac{\partial F_{i}}{\partial x_{j}}\right|_{x_{k}=\varphi_{k}\left(y_{1}, ., y_{p}\right)} \xi_{j}=\phi_{i}\left(\xi_{t}, \ldots, \xi_{i}, y_{i}, \ldots, y_{p}, t\right)$ where the formal power series $\phi_{i}$ are such that $\phi_{i}\left(0, \ldots, 0 ; \underline{y}_{1}, \ldots, y_{p} ; 0\right)=0$
i.e $\underline{\xi}_{j}=\psi_{j}\left(\underline{\xi}_{d}, \ldots, \underline{\xi}_{n} ; \underline{y}_{i}, \ldots, \underline{y}_{p} ; t\right)$
with the same conditions on $\Psi_{j}$. This system is easily solved by iteration .

We show here that, as a consequence of the Slavnov identity, $\Gamma_{c e}^{-1}\left(\Gamma_{A^{2} A^{-} \varphi_{\varphi_{2} \varphi_{2}}}-\Gamma_{A_{L_{2}}}^{2}\right)$ is finite at $p^{2}=m_{q}^{2}$ and thus can be required to vanish. In other words, the $\oint \pi$ ghost mass is always degenerate with one of the $A^{L}, \varphi_{2}$ ghost masses, Complete degeneracy then characterizing spontaneous breakdown, We first write the Slavnov identity in terms of the vertex functional :

$$
\begin{aligned}
& \left.\frac{\partial}{\rho} \Gamma\right) \equiv \int d x\left(-\bar{c} \partial_{\mu} \delta_{A_{\mu}} \Gamma-\bar{e}_{1} \delta_{\varphi_{1}} \Gamma \delta_{\eta_{2}} \Gamma+\bar{e}_{2} \delta_{\varphi_{2}} \Gamma \delta_{\eta_{1}} \Gamma\right. \\
& \left.+\bar{m} \bar{c} \delta_{\varphi_{2}} \Gamma-\bar{e} A_{\mu} \partial_{\mu} \delta_{e} \Gamma+\vec{\rho} \varphi_{2} \delta_{c} \Gamma\right)(x)=0
\end{aligned}
$$

(AIII, 1)
Within the $A_{\mu}, \varphi_{2} \quad$ channel, we get :

$$
\begin{align*}
& i p_{\mu} \Gamma_{A_{\mu} \varphi_{2}}(p)-\bar{\rho} \Gamma_{\bar{c}_{c}}\left(p^{2}\right)-\gamma\left(p^{2}\right) \Gamma_{\varphi_{2} \varphi_{2}}\left(p^{2}\right)=0 \\
& p_{\mu} p_{\nu} \Gamma_{A_{\mu} A_{\nu}}(p)-\bar{a} p^{2} \Gamma_{\bar{c} c}\left(p^{2}\right)+i \gamma\left(p^{2}\right) p_{\mu} \Gamma_{A_{\mu} \varphi_{2}}(p)=0 \tag{AIII,2}
\end{align*}
$$

where

$$
\begin{equation*}
\gamma\left(p^{2}\right)=\bar{e}_{2} \Gamma_{\bar{e} \eta_{1}}\left(p^{2}\right)+\bar{m} \tag{AIII,3}
\end{equation*}
$$

Thus

$$
\begin{align*}
& \Gamma_{\varphi_{2} \varphi_{2}}\left(p^{2}\right)=\frac{1}{\partial\left(p^{2}\right)}\left[i p_{\mu} \Gamma_{A_{\mu} \varphi_{2}}(p)-\bar{\rho} \Gamma_{\bar{c} e}\left(p^{2}\right)\right]  \tag{AIII,4}\\
& p_{\mu} p_{\nu} \Gamma_{A_{\mu} A_{\nu}}(p)=i \gamma\left(p^{2}\right) p_{\mu} \Gamma_{A_{\mu} \varphi_{\nu}}(p)+\bar{a} p^{2} \Gamma_{\bar{c} C}\left(p^{2}\right) \\
& D=\operatorname{det}\left(\begin{array}{ll}
\Gamma_{A^{L} A^{L}} & \Gamma_{A^{L} \varphi_{2}} \\
\Gamma_{A^{L} \varphi_{2}} & \Gamma_{\varphi_{2} \varphi_{2}}
\end{array}\right)=\frac{d}{p^{2} \gamma\left(p^{2}\right)}\left[-\bar{\rho} \bar{a} p^{2}\left(\Gamma_{\bar{e} c}\left(p^{2}\right)\right)^{2}\right. \\
& +i p_{\mu} \Gamma_{A_{\mu} \varphi_{2}}(p) \Gamma_{\bar{e} e}\left(p^{2}\right)\left(\bar{a}^{2} p^{2}-\bar{\rho} \gamma\left(p^{2}\right)\right) \\
& { }_{\text {Hence: }} p_{\mu} p_{\nu} \Gamma_{A_{\mu} A_{\nu}}(p)=i \gamma\left(p^{2} p_{\mu} \Gamma_{A_{\mu} \varphi_{2}}(p)+\bar{Q} p^{2} \Gamma_{\bar{c} c}\left(p^{2}\right)\right. \\
& D=\operatorname{det}\left(\begin{array}{ll}
\Gamma_{A^{L} A^{L}} & \Gamma_{A^{L} \varphi_{2}} \\
\Gamma_{A^{L} \varphi_{2}} & \Gamma_{\varphi_{2} \varphi_{2}}
\end{array}\right)=\frac{1}{\beta^{2} \gamma\left(p^{2}\right)}\left[-\bar{\rho} \bar{a} p^{2}\left(\Gamma_{\bar{e} c}\left(b^{2}\right)\right)^{2}\right.
\end{align*}
$$

(AIII,5)

Thus, first
furthermore its vanishing implies

$$
a p^{2}-\left.\bar{\rho}\left(\bar{m}+\bar{e}_{2} \Gamma_{\bar{e} \eta_{1}}\left(p^{2}\right)\right)\right|_{p^{2}=w_{a}^{2}} \equiv a p^{2}-\left.\bar{\rho} \gamma\left(p^{2}\right)\right|_{b^{2}=w_{a}^{2}}=0
$$

since $\Gamma \neq 0$, provided one stays away from the restricted't toft gauge $(\rho=\alpha e v) . A_{\mu}, \varphi_{2}$.
Looking now at the $\oint \pi$ propagator equation

$$
\begin{equation*}
\left[\bar{a} p^{2}-\left(\bar{\rho} \bar{m}+\frac{2}{\mu}\right)\right]_{\bar{e} c}\left(p^{2}\right)-\bar{\rho} \bar{e}_{2} \mathcal{G}_{\bar{e} \eta_{1,2}}=\bar{\alpha} \tag{ALI,,7}
\end{equation*}
$$

the absence of a pole in the left hand side at $p^{2}=\omega_{a}^{2}$ yields:

$$
\begin{gather*}
\bar{a} p^{2}-\left(\bar{\rho} \bar{u}+\bar{\mu}^{2}\right)-\left.\bar{\rho} \bar{e}_{2} \Gamma_{\bar{e} \eta_{l}}\left(p^{2}\right)\right|_{\substack{p^{2}=\mu_{q}^{2} \\
\text { and use of }}}=0  \tag{AIII,8}\\
\text { after multiplication of (AIII, 7) through } \Gamma_{\bar{e} c}
\end{gather*}
$$

$$
G_{\bar{c} \eta_{1}}=\Gamma_{\bar{c} \eta_{1}} G_{\bar{c} c}
$$

after multiplication of (AIII, ) through ec

Hence comparing with EO. AIII, 6) , we get:

$$
\begin{equation*}
\bar{\mu}=0 \tag{AIII,IO}
\end{equation*}
$$

## - APPENDIX IV -

We have shown in chapter III (Eq(8I)) that, in the limit $\varepsilon \underset{\sim}{\infty}$ the commutator of $\Delta_{1,2}$ with $\&$ is equal to $e_{i} s_{i}$. We thus infer that the infinite part of $\Delta_{i, \varepsilon}$ as given by the Zimmermann-Wilson expansion is a symmetric insertion with coefficients going to infinity as $\mathcal{E} \rightarrow 0$ The finite part $\Delta_{i}$ will then be given by $\left[\delta, Q_{i}\right]$ where $Q_{i}$ is the finite part of $Q_{i, \varepsilon}$
It is possible but lengthy to verify these statements by looking at the Zimmermann-Wilson expansion of $Q_{i, \varepsilon}$. In the case of $Q_{5, \varepsilon}$ the calculation is however reasonably simple:

$$
\begin{align*}
& \int d x\left[T \varphi_{2}(\varepsilon) c(-\varepsilon)\right](x)=\frac{i}{\hbar}\left\langle\int d x T[\varphi(\varepsilon) c(-\varepsilon)](x) N_{2}\left[\bar{c} \varphi_{2}\right](0)\right\rangle \int d x \eta_{2}(x) \\
& +\left\langle\int \delta x T\left[\varphi_{2}(\varepsilon) c(-\Sigma)\right](\infty) \varphi_{2}(0) \bar{C}(0)\right\rangle \cdot \int d x\left\{\int_{2}\left[\varphi_{2}(\varepsilon) c(-\varepsilon)\right](x)\right\} \tag{AIV,1}
\end{align*}
$$

where the second coefficient is amputated on its $\widetilde{\varphi}_{2} \bar{e}$ arguments. The only singular coefficient in this expansion is

$$
\begin{equation*}
\left.<\int d x T\left[\varphi_{2}(\varepsilon) e(-\varepsilon)\right](x) N_{2}\left[\bar{c} \varphi_{2}\right](0)\right\rangle \tag{AVID}
\end{equation*}
$$

which diverges logarithmically. The singular part of $\Lambda_{5, \varepsilon}$ is thus proportional to $\left[d, \int d x \eta_{2}(x)\right] \sim \int d x J_{l}^{J}(x)$ which is symmetrical $\quad\left(c f\left(E_{C_{1}}(92)\right.\right.$ ) as expected
By a similar but more involved analysis one can evaluate the singular part of $\Delta_{4,2}$ which assumes the form

$$
\omega(\varepsilon) \int d x J_{1}(x)+\omega(\varepsilon)\left\{\int d x\left(J_{1} \delta_{J_{1}}+\eta_{2} \delta_{\eta_{2}}+J_{2} J_{2}+\eta_{1} \delta_{\eta_{1}}+\frac{\bar{m}}{\overline{e_{2}^{2}}} \eta_{1} \delta_{\xi}\right)(x)(A I V, 3)\right.
$$

$$
\left.+\Delta_{5}\right\}_{\text {and } \omega}
$$

are, in the limit $\mathcal{E} \rightarrow 0$ logarithmically divergent
The resulting finite parts are however not suitable for our purpose because, due to the occurence of graphs which are $\varphi_{1}$ one particle reducible they do not vanish upon application of the operator $\sum^{1}$ plays (ce

Since the $Q_{l_{1}} 1_{3}$ carry the quantum numbers of $e \varphi_{2}$
we have:

$$
(\mathrm{AIV}, 4)
$$

where

$$
\begin{equation*}
\left.\Gamma\left(Q_{i}\right)=\frac{i}{\hbar}<T N_{2}\left[\bar{c} \varphi_{2}\right](0) Q_{i} \tilde{\varphi}_{1}(p)\right\rangle \tag{AIV,5}
\end{equation*}
$$

is involved in the expansion:
where the upperscript $I_{1}$ denotes the set of graphs which are one particle irreducible with respect to the pair $\bar{C} \varphi_{2}, Q_{i}$.

Since $\int d x\left[J_{1} \delta_{J_{1}}+\eta_{2} \delta_{\eta_{2}}\right](x)$ is obviously a symmetric insertion, adding $\bar{e}_{1} \Gamma^{\left(Q_{i}\right)}\left(M^{2}\right) \int d x\left[J_{1} \delta_{J_{1}}+\eta_{2} \delta_{\eta_{2}}\right](x)$
does not change the covariance of $\left\langle Q_{i}\right]$ and produces insertions which leave the physical normalization conditions (Eq. $3(3,4,5,6,7)$ ) invariant.
We now want to show that the insertions $\Delta_{i}^{0}$ leave the normalization condition Eq. $(31,8)$ unchanged, These insertions can be replaced by $\Lambda_{i}=\left[\ell, Q_{1}\right]$ modulo terms which trivially do not contribute to the calculation.
We shall show that:

$$
\Gamma_{\bar{c} c}^{-2} \operatorname{det}\left(\begin{array}{ll}
\Gamma_{A^{\prime} A^{\prime}} & \Gamma_{A^{\prime} \varphi_{2}}  \tag{AIV,7}\\
\Gamma_{A^{\prime}} \varphi_{2} & \Gamma_{\varphi_{2} \varphi_{2}}
\end{array}\right) \equiv C_{c \bar{c}}^{2} D
$$

remains regular at $t h e^{A} \phi_{\frac{1}{2}}^{\pi}$ mass, upon insertion of $\Delta_{i}$.

$$
\begin{align*}
& \Delta_{i}\left(G_{C c}^{2} D\right)=Q_{e \bar{c}} D\left(2\left[\Delta_{i} G_{e r}\right]\right. \\
& \left.\left.-G_{e \bar{c}} T_{i}\left\{\left(\begin{array}{ll}
\Gamma_{A^{L} A^{L}} & \Gamma_{A^{L} \varphi_{L}} \\
\Gamma_{A^{L} \varphi_{2}} & \Gamma_{\varphi_{2} \varphi_{2}}
\end{array}\right)\left[\begin{array}{ll}
\Delta_{i} & G_{A^{L} A^{L}} \\
G_{A^{L} \varphi_{2}} \\
C_{\varphi_{L} A_{L}} & G_{\varphi_{2} \varphi_{2}}
\end{array}\right)\right]\right\}\right) \tag{AIV,8}
\end{align*}
$$

$$
\begin{aligned}
& \sum_{p_{\text {by }}} \frac{Q_{i} Z}{} Z-\bar{e}_{1} \sum_{p^{k y y}} \int d x\left(J_{i} \delta_{\eta_{2}}\right)(x) Q_{i} Z \\
& =-\bar{e}_{1} \sum_{j h_{y}} \int d p \tilde{J}_{i}(p) \Gamma^{\left(Q_{i}\right)} \delta_{J_{(p)}} Z
\end{aligned}
$$

$$
\begin{aligned}
& =-\bar{e}_{1} \Gamma\left(M^{2}\right) \quad \sum_{p h y s} \int d x\left(\sigma_{1} \delta_{J_{1}}+q_{2} \partial_{\eta_{2}}\right)(x) Z
\end{aligned}
$$

where the matrix $\left\|G_{i j}\right\|$ is the inverse of the matrix $\left\|\Gamma_{i j}\right\|$. By commuting $\delta_{\xi} \delta_{\bar{\xi}}{ }_{\lambda}{ }^{\prime}$ through $\&$ we get:

$$
\begin{align*}
{\left[\Delta_{i} G_{e \bar{c}}\right](p) } & =\left\langle T \tilde{\widetilde{c}}(p) G(0) Q_{i}\right\rangle \\
& =G_{e \bar{c}}(p)^{2}\left\langle T \tilde{\underline{c}}(p) \mathcal{G}^{(0)} Q_{i}\right\rangle \tag{AIV,9}
\end{align*}
$$

where underlining means amputation.
Similarly

$$
\begin{align*}
& {\left[\Delta_{i} G_{c i}^{2} D\right](p)=2 G_{c \bar{c}}^{2}\left(p^{2}\right) D_{(p)}\left[\left\langle T \tilde{\underline{e}}(p) G(0) Q_{i}\right\rangle\right.} \\
& +\left\langle T \tilde{\varphi}_{2}(p)\left[\bar{e}_{2} N\left[\bar{e} \varphi_{1}\right]+\bar{m} \bar{e}\right] \cos Q_{i}\right\rangle \\
& -p^{2}\left\langle T \widetilde{\partial}_{\mu} \tilde{A}_{\mu}(p) \bar{e}(0) Q_{i}\right\rangle \tag{AIV,IO}
\end{align*}
$$

Thus we only have to make sure that the bracket is regular at the $\phi \pi$ squared mass. Now the first term is singular due to the occurence of the $\mathcal{G}$ propagator, and the last two terms are singular due the occurence of the $\phi \pi$ propagators The $\mathcal{G}$ propagator can be factorized using the Slavnov identities:

$$
\begin{align*}
& \left\langle T \tilde{g}_{\mathcal{G}}(p) \varphi_{2}(0)\right\rangle=-\left\langle T\left(\bar{e}_{2} N_{2}\left[\bar{e} \varphi_{i}\right]+\bar{m} \bar{e}\right)(0) \tilde{c}(p)\right\rangle \\
& \left\langle T \tilde{G}(p) \partial_{\mu} A(0)\right\rangle=p^{2}\langle T \tilde{c}(0) \tilde{c}(p)\rangle \tag{AIV,11}
\end{align*}
$$

so that:
$\left\langle T \tilde{\tilde{e}}(p) \tilde{G}(0) Q_{i}\right\rangle=-\left\langle T \tilde{\tilde{c}}(p) \varphi_{2}(0) Q_{i}\right\rangle\left\langle T\left(\bar{e}_{2} N_{2}\left[\bar{c} \varphi_{1}\right]+\bar{m} \bar{e}\right)(0) \tilde{c}(p)\right\rangle$

$$
\begin{equation*}
+p^{R}\left\langle T \tilde{\underline{\tilde{c}}}(p) \partial_{\mu} A_{\mu}(0) Q_{i}\right\rangle\langle T \tilde{e}(0) \tilde{c}(p)\rangle \tag{AIV,12}
\end{equation*}
$$

Now the $\phi \pi$ equation of motion allows to replace $\left[\bar{e}_{2} N_{2}\left[\bar{\varepsilon} \varphi_{1}\right]+\bar{m} \bar{c}\right](0)$ by a term proportional to $\square \bar{e}(\mathcal{)}$ un to a regular term, so that the factors $\left\langle T \bar{c}(0) \tilde{U_{(p)}}\right\rangle \quad$ undo the $\overline{\boldsymbol{c}}$ amputation involved in their factors and produce an exact cancellation with the last two terms in $E q_{0}(A I V, 10)$.

## - APPENDIX VI.

This appendix deals with a number of details in the unitarity proof of ch. IV. We first discuss the properties of the asymptotic ghost field wave operators $L$ and of the corresponding asymptotic field two point function $S_{+}$. Within the coupled $\left(\partial_{\mu} A_{\mu}, \varphi_{2}\right)$ channels $L$ can be taken as a polynominial approximation to the matrix

$$
\left(\begin{array}{ll}
\Gamma_{g q} & \Gamma_{\bar{g} q} \\
\Gamma_{\bar{g} q} & \Gamma_{\bar{g} q}
\end{array}\right)
$$

where

$$
\begin{align*}
& g=\bar{Q} \partial_{\mu} A_{\mu}+\bar{\rho} \varphi_{2} \\
& \bar{g}=-\bar{Q} \partial_{\mu} A_{\mu}+\bar{\rho} \varphi_{2} \tag{AV,1}
\end{align*}
$$

Denoting $x=\rho^{2}-m_{c}^{2}$, and taking into account: (i) the normalization condition (31, 8), which implies the occurence of a double zero in der $L$ ar $x=0$ (ii) the lack of singularity in the $\mathcal{G} \mathcal{G}$ propagator, which follows from the Slavnov identity and implies the occurence of a double zero in $\Gamma \bar{G} \bar{g}$ a $x=0$,
We can parametrize $\quad$ in the following form: We can parametrize $L$ in the following form:

$$
L=\left(\begin{array}{cc}
A+\beta x & \gamma^{x} \\
\gamma x & 0
\end{array}\right)+O\left(x^{2}\right)
$$

The last term giving corrections of order $x^{2}$.
The corresponding matrix propagator is:

$$
\left(\begin{array}{ll}
G_{g g} & G_{g \bar{y}} \\
C_{g \bar{g}} & G_{\bar{g} \bar{g}}
\end{array}\right)=-\frac{1}{\gamma^{2} x^{2}}\left(\begin{array}{ll}
0 & -\gamma x \\
-\gamma x & A+\beta x
\end{array}\right)
$$

and the $S_{+}$operator is given by:

$$
\begin{align*}
& \overbrace{\text { that }}^{+} S_{t}=\theta\left(p_{0}\right)\left(\begin{array}{ll}
0 & \frac{1}{\gamma} \delta(x) \\
\frac{d}{\gamma} \delta x & -\frac{\beta}{\gamma^{2}} \delta(x)+\frac{\theta}{\gamma^{2}} \delta^{\prime}(x)
\end{array}\right)  \tag{AV,4}\\
& \text { so that } \\
& \theta\left(p_{0}\right)\left(\begin{array}{cc}
A\left[\overleftarrow{x} \delta(x)+\delta(x) \vec{x}+\overleftarrow{x} \delta^{\prime}(x) \vec{x}\right]+\beta \stackrel{\rightharpoonup}{x} \delta(x) \vec{x} & \gamma \stackrel{x}{x} \delta(x) \vec{x} \\
\gamma \stackrel{x}{x} \delta(x) \vec{x} & 0
\end{array}\right)^{(A V, 5)}
\end{align*}
$$

where the symbols $\vec{X}, \stackrel{x}{x}$ are to remind that the usual identities: $x \delta(x)=x^{2} \delta^{\prime}(x)=0$ cannot be used here because this kernel is to be tested with functions which have poles at $x=0$.
Concerning the Faddeev-Popov fields, let us define

$$
\begin{align*}
& \bar{e}=c \\
& \bar{e}=2 \bar{\rho}\left[\bar{m}+\bar{e}_{z} \Gamma_{e_{p}}\left(m_{c}^{2}\right)\right] \bar{c} \tag{AV,6}
\end{align*}
$$

Using the results of Appendix III we get:

$$
\begin{equation*}
G_{e \varepsilon}=\frac{1}{\partial x}+\text { regulon Tonus } \tag{AV,7}
\end{equation*}
$$

and

$$
i t\left(\stackrel{L}{L} S_{+} \vec{L}\right)_{\phi \pi}=\gamma * \underset{x}{ } \delta(x) \vec{x}\left(\begin{array}{lr}
1 & 0  \tag{AV,8}\\
0 & -1
\end{array}\right)
$$

The $A_{0}$ operator $E q(101)$ can now be written

where $\int_{\varphi}^{-\lambda} e^{(-p)}$ is the source of the field $\varphi^{\dagger}$ that is used in the definition of the antitime ordered functional.
Before pursuing, let us regularize the $\delta$ functions according to

$$
\begin{equation*}
\delta(x) \rightarrow \delta_{\varepsilon}(x)=\frac{e^{-\frac{x^{2}}{\varepsilon}}}{\sqrt{\pi \varepsilon}} \tag{AV,10}
\end{equation*}
$$

so that we may forget about the arrows on the $\vec{x}$ variables.
Owing to the invariance of the lagrangian under the transformation:

$$
\begin{equation*}
c \rightarrow-\bar{e} \tag{AV,11}
\end{equation*}
$$

$(A V, \ldots$ )

Taking into account (Eq.(43)we get:
$\left[{\underset{J}{J_{\bar{g}}}}(p), \vec{\ell}\right]=\delta_{\underset{\sim}{e}}+\cdots(x)$
$\left[\delta_{\underset{J_{g}}{ }(p),} \vec{\jmath}\right]=-\frac{\bar{\alpha}}{\gamma} \times \delta_{\overline{J_{e}}}(p)+O\left(x^{2}\right)$

$$
(\mathrm{AV} ; j)
$$

$\left\{\vec{\delta}_{\tilde{J}}^{\bar{e}}(p), \vec{\lambda}\right\}=0$

$$
+O(\varepsilon)
$$

Since the propagator attached to the $\mathcal{g}$ and $\bar{e}$ legs have only simple poles the $\beta$ dependent term in the righthand side of $(E q,(A V, I 4))$ is of order $\varepsilon$ This does not happen for the term involving $\bar{\delta}_{\sim}^{J_{\bar{g}}}$ because the $(\bar{g}, \bar{g})$ propagator has a double pole.
However we have

$$
\begin{equation*}
x \mathcal{G}_{\bar{y}}\left(p^{2}\right)=-\frac{A}{\gamma} C_{C_{y}}\left(p^{2}\right)+\text { Reguelon Tenures. } \tag{AV,15}
\end{equation*}
$$

Since the $(G, G)$ propagator has no pole we have:
$\times \vec{\delta}_{\tilde{J}_{\bar{g}}(p)} \vec{Z}=-\frac{A}{\gamma} \vec{\delta}_{\tilde{J}_{\mathcal{G}}(p)} \vec{Z}$
+Regular terms

The vanishing of the $A$ dependent terms is due to the absence of double poles in the $G$ and $\bar{e}$ propagators.
As a consequence we get:

$$
\begin{equation*}
[A, \vec{J}]=[\vec{J}, A]+O(\varepsilon) \tag{AV,18}
\end{equation*}
$$

where $\stackrel{\mathcal{A}}{ }_{*}^{*}$ is the Slavnov operator which characteri::es the anti-time ordered functional.
Indeed $E q(A V, 18)$ is a consequence of the symmetry of both $t$ and $[\vec{f}, \vec{J}]$ with respect to the transposition and the complex conjugation of the sources

$$
\begin{aligned}
& {[A, \delta]=\int f_{0} \theta\left(p_{0}\right)\left\{\begin{array} { l } 
{ \frac { \delta _ { n } } { T ( - b ) } }
\end{array} \left[2 A x \delta(x)+A x^{2} \delta^{\prime}(x) \cdots\right.\right.}
\end{aligned}
$$

$$
\begin{aligned}
& \text { which yields }
\end{aligned}
$$

We are now in condition to state the following identity:

In the first step of this reduction, the $O(\varepsilon)$ term takes into account
contributions of the kind:

The second step makes use of the Slavnov identities

$$
\begin{align*}
& \vec{s} S_{\text {flags }}(J)=0  \tag{AV,20}\\
& S_{\text {flay }}^{+}\left(\frac{J}{I}\right) \hat{J}^{*}=0
\end{align*}
$$

and takes advantage of the zero source condition by commuting to the left and to the right.
The last step is a trivial consequence of $\operatorname{Eq}(A V, 18)$. Going back to the expression for $\mathcal{A}$, and taking into account the symmetry property, one gets Eq. ( $10 \%$ of section IV.

## - APPENDIX VI-

## A CLASS OF LOCAL GAUGE INVARIANT OPERATORS

In order to define a local operator $\Theta(x)$ of dimension $d$, we shall first consider an effective lagrangian .

$$
\begin{equation*}
\mathcal{L}_{\text {eff }}^{(\omega)}(x)=\mathcal{L}_{\text {eff }}(\underline{\varphi}, \underline{J}, \underline{x})(x)+\omega(x) N_{d}[\Theta(x)] \tag{AVI,1}
\end{equation*}
$$

where $\mathcal{W}$ is a classical field of dimension 4-d.
The first criterion for gauge invariance is

$$
\begin{equation*}
\oint Z^{c}(\underline{J}, \eta, \omega)=O\left(\omega^{2}\right) \tag{AVI,2.}
\end{equation*}
$$

where $\&$ is the operator defined in Eq (43). Assuming that ©q.(AVI, 2) has solutions, they are in one to one correspondence with those found at the tree level. They will be further specified by as many physical normalization conditions as are necessary to specify physical operators of this type at the tree level (namely modulo the ideal generated by operators which vanish on the physical subspace) . It follows that $\Theta$ is ambiguous up to a linear combination of operators whose tree approximations vanish on the physical subspace .

The proof of gauge invariance then proceeds as usual (ch .III)
Keeping terms of the first order in $\boldsymbol{W}$, one looks for the most general solution of

$$
\partial_{\lambda} Z(\underline{J}, \eta, \omega)=\frac{i}{\hbar} \Delta_{\lambda}^{(\omega)} Z(\underline{J}, \eta, \omega)
$$

which is of the form

$$
\begin{equation*}
\Delta_{\lambda}^{(\omega)}=\Delta_{\lambda}+\int d x \omega(x)\left[\Sigma_{i} f_{i} \Theta_{i}^{s}(x)\right] \tag{AVI,4}
\end{equation*}
$$

where the second term in the right hand side of E $\mathcal{A}(\mathrm{AVI}, 4)$ is a perturbation of the $\boldsymbol{\omega}$ dependent part of the solutions of Ego (AlI, 2 ) in the tree approximation Testing now Eq(AVI, 4) with the physical normalization conditions which specify
$(H)(x)$ shows that the problem reduces to check that the perturbations of operators which have nu physical restriction in the tree approximation retain this property to all orders

Finally the stability of the physical subspace under application of
(4) (x)
(K) , up to the zero norm states is a consequence of Eq(AVI; 2) as follows from a slight generalization of the argument in Ch . IV: defining $S(\omega)$ by replacing $Z(J, \eta)$ by $Z(J, \mu, \omega)$ in the LSZ definition of $S$ in the overall Pock space, ( 4 ( $x$ ) is defined according to

$$
\begin{align*}
& (H)(x)=\left.\frac{\hbar}{i} S^{-1} \frac{\delta S}{\delta \omega(x)}\right|_{\omega=0} \\
& H^{+}(x)=-\left.\frac{\hbar}{i} \frac{\delta S^{+}}{\delta \omega(x)} S\right|_{\omega=0} \tag{AVI,5}
\end{align*}
$$

Let $E_{0}$ be the projector on the physical subspace generated by $\varphi_{\lambda}$ and $A_{\mu}^{\top}$ quanta. One wishes no show that

$$
E_{0}^{\mu} H_{(x)}^{+} E_{0} H_{y} E_{0}=E_{0} E_{(x)}^{+} H_{(y)} E_{0}
$$

ice

$$
E_{0} \frac{\delta S^{\dagger}}{\delta \omega(x)} \frac{\delta S}{\delta \omega(y)} E_{0}=\left.E_{0} \frac{\delta S^{\dagger}}{\delta \omega(x)} E_{0} S^{+} \frac{\delta S}{\delta \omega(y)} E_{0}\right|_{\omega=0}
$$

where the unitarily of $S$ has been used
Eq(AVI, 7) follows simply from

$$
\begin{equation*}
E_{0} S E_{0} S^{\top} E_{0}=E_{0} \tag{AVI,8}
\end{equation*}
$$

which is the result of Ch IV
and from the identities
$E_{0} \frac{\delta S^{\dagger}}{\delta \omega_{(x)}} \frac{\delta S}{\delta \omega_{y}} E_{0}=\left.E_{0} \frac{\delta S^{\dagger}}{\delta \omega_{(x)}} E_{0} \frac{\delta S}{\delta \omega_{(y)}} E_{0}\right|_{\omega=0}$
$E_{0} \frac{\delta S^{\dagger}}{\delta(\omega)(x)} S E_{0}=E_{0} \frac{\delta S^{\dagger}}{\delta \omega(x)} E_{0} S E_{0}$
(AVI. 9 )

$$
\omega=0 \quad y=0
$$

which are consequences of the first criterion for gauge invariance :

$$
\left[\frac{\delta}{\delta \omega}, \delta\right]=0
$$

(AVI , 10)
and of the argument in Ch . IV.

## Example

a) $d=2$
$C=+1$
$\oplus \quad$ is a linear combination of $\left\{\varphi_{1}, \varphi_{1}^{2}, \varphi_{2}^{2}, A_{\mu} A_{\mu}, \bar{e} c\right\}$
$\&\left(\mathbb{H}\right.$ is a linear combination of $\left\{\varphi_{2} \bar{e}, \varphi_{1} \varphi_{2} \bar{e}, \bar{c} \partial A_{\mu} \gamma(c h\}_{j} ;\right.$ so is the term $O(\omega)$ in $f Z(J, y, \omega)$
Thus there is no anomaly i, e. there exists one invariant local operator which is a perturbation of

$$
\varphi_{1}^{2}+\varphi_{2}^{2}+2 v \varphi_{1}
$$

which is non zero in the physical subspace. This operator is completely determined by egg.

$$
\left\langle\Omega,(\leftrightarrow)(x) \varphi_{d, i n}(y) \Omega\right\rangle=i \Lambda_{M}^{+}(x-y)
$$

and can serve as a gauge invariant interpolating field operator for $\varphi_{i, u}$
b) $d=3 \quad C=-1$ vector operator

It is trivial that $\partial_{\mu} G_{\mu \nu} \quad$ solves the problem :

$$
\left[\left(\square g_{\mu \nu}-\partial_{\mu} \partial_{\nu}\right) \delta_{J_{\nu}(x)}, \delta\right]=0
$$

$$
\partial_{\lambda} \prod_{i}^{n}\left(\square g_{\mu_{i} \nu_{i}}-\partial_{\mu_{i} \nu_{i}}^{\partial}\right) \delta_{\substack{\gamma_{i}\left(x_{i}\right)}} \sum_{p k y s} Z_{J=\eta}=0 \quad\left(\lambda=\alpha, m_{c}^{2}\right)
$$

## Appendix VII

This appendix is devoted to the main steps involved in the treatment of an extended class of gauges involving quadratic terms odd under charge conjugation In the tree approximation, the Slavnov transformation (cf Eq (24) is now taken to be:

$$
\begin{align*}
& \delta A_{\mu}=\lambda \partial_{\mu} \bar{e} \\
& \delta \varphi_{1}=-\lambda \varphi \varphi_{2} \bar{e} \\
& \delta \varphi_{2}=\lambda e\left(\varphi_{1}+v\right) \bar{c} \\
& \delta c=\lambda\left(\partial_{\mu} A_{\mu}+\rho \varphi_{2}+\delta \varphi_{1} \varphi_{2}\right)=\lambda g  \tag{AVII,1}\\
& \delta \bar{e}=0
\end{align*}
$$

The most general lagrangian fulfilling the corresponding Slavnov identity is now: $\mathcal{L}=-\frac{Z_{2}}{4} G_{\mu_{0}} G_{\mu_{0}}+Z_{1}\left(D_{\mu} \varphi\right)^{*} D_{\mu} \varphi+\mu^{2} \varphi^{*} \varphi \rightarrow g\left(\varphi^{*} \varphi\right)^{2}$
$-\frac{1}{2}\left[\frac{g^{2}}{2}+\bar{c} \frac{\delta g}{\delta \Lambda} c\right]+\beta\left[\frac{A_{1} A_{\mu}}{2}-\bar{c} e+\frac{\sigma}{e} \frac{\varphi_{1}^{2}}{2}+\frac{\rho}{e} \varphi_{1}\right]$
where now

$$
\begin{equation*}
\frac{\delta g(x) r}{\delta \lambda(y)}=m(x, y)=\left[\square+\rho e v+e(\rho+\sigma v)+e \sigma\left(\varphi_{1}^{2}-\varphi_{2}^{2}\right)\right](x) \delta(x-y) \tag{AVII}
\end{equation*}
$$

Keeping the normalization conditions (Eq.(31) unchanged Eq. (32) is unchanged except for Eq. $(32,3)$ which now reads

$$
\begin{equation*}
M^{2}=\frac{2}{Z_{1}}\left(6 g v^{2}-\mu^{2}-\frac{\beta \sigma}{2 e}\right) \tag{AVII,4}
\end{equation*}
$$

But due to Eq. $(32,8)(\beta=0)$, the overall algebraic system . Bq(32) is unchanged We now turn to the details of the Slavnov identity which we shall express in linear form as in $E_{4}(43)$. Before doing so we need to introduce at least one external field $\gamma$ coupled to $\varphi_{1} \varphi_{2}$, to which we assign dimension two ard odd charge conjugation quantum number. The corresponding term however undergoes a variation under the Slavnov transformation (AVII, l), which forces us also to introduce at least one field coupled co $\left(\varphi_{1}^{2}-\varphi_{2}^{2}\right) \bar{e}$ However, for later use, we shall right away introduce three fields of dimension one, $\vec{\beta} \equiv\left(\beta_{1}, \beta_{2}, \hat{\beta}_{2}\right.$
coupled co three independent linear combinations of: $\overline{\bar{e}} \equiv\left(\bar{\varphi}_{1}, \bar{\varphi}_{2}, \bar{\varphi}_{3}\right)$

$$
\equiv\left(\varphi_{1}^{2} \overline{\bar{C}}, \varphi_{2}^{2} \overline{\overline{ }}, A_{\mu} A_{\mu} \overline{\bar{C}}\right) \quad \text { and also a field of dimension }
$$

dimension zero $\tau$ coupled to $A_{\mu} \bar{C} \partial_{\mu} \bar{C}$. Thus we have introduced external. fields coupled to a system of operators which is closed under Slavnov transior mations. The most general lagrangian invariant under charge conjugation, $\phi \pi$ neutral and consistent with power counting is now

$$
\begin{aligned}
& \mathscr{L}(\varphi, \underline{J}, \eta, \gamma, \vec{\beta} \tau)=\mathcal{L}(\varphi)+\eta_{1}\left(z, \bar{e} \varphi_{1}+z_{1}^{\prime} \bar{e}\right)+\eta_{2} \dot{\xi}_{2} \bar{e} \varphi_{2} \\
& +\gamma\left(Q_{1} \varphi_{1} \varphi_{2}+Q_{2} \varphi_{2}+Q_{3} \partial_{\mu} A_{\mu}\right)+\beta_{i}\left(B_{i j} \bar{e}_{j}+\mu_{i} \varphi_{1} \bar{e}\right. \\
& \left.+v_{i} \bar{e}+\omega_{i} \square \bar{c}\right)+\tau Q_{4} A_{\mu} \bar{e} \partial_{\mu} \bar{e}+Q_{5} \gamma^{2}+J_{\mu} \varphi_{1} \\
& +J_{2} \varphi_{2}+J_{\mu} A_{\mu}+\bar{\xi} e+\xi \bar{e}
\end{aligned}
$$

and the Slavnov identity assumes the general form which will be needed later:

$$
\begin{aligned}
& g_{\sigma} z^{e}=g z^{e}+\int d x\left[-\bar{\sigma} \bar{\xi} \delta_{\gamma}+\gamma\left\{\lambda_{1} \square \delta_{\xi}\right.\right. \\
& \left.\left.+\lambda_{2} \delta_{\xi}+\lambda_{3} \delta_{\eta_{1}}+\vec{b} \delta_{\vec{\beta}}\right\}+\vec{d} \cdot \vec{\beta} \delta_{\tau}\right](x) \vec{Z}=0
\end{aligned}
$$

(AVI, ${ }^{\circ}$
where however in spite of the huge number of parameters involved in (AVII, 3 ) the coefficients in $\&_{\sigma}$ are always constrained by

$$
\vec{d} \cdot \vec{b}=0
$$

(AVII 7)
because $b_{i} \alpha\left(B_{1 i}^{-1}-\left(B^{-1}\right)_{2 i} \quad\right.$ and $\quad d_{i} \propto B_{i 3} \quad(i=1,2,3)$.
One can in fact verify directly that this is the only constraint on the coffin cients of the Slavnov identity
We are now ready to prove that one can fulfill a Slavnov identity of the type (AVII, 6) to all orders in $t$, with coefficients constrained by $E_{\text {A }} A$ II, , Performing a Slavnov variation of the type (AVII, l) on an effective lagrange a
of the form ${ }^{n} N_{4} \mathcal{L}(\underline{\varphi}, \underset{J}{\boldsymbol{J}} \boldsymbol{\eta}, \gamma, \vec{\beta}, \tau) \quad$ (cf Eq(AVII, 5)) yields:

$$
g_{\sigma} z^{c}=\sum_{i}^{32} c_{i} \Delta_{i} Z^{c}
$$

(AlI, 8 )
where the first $23 \Delta_{i}$ are listed in Eq d 26 ), and the last nine $\Delta_{i}$, are:
(24) $\int d x[\gamma \bar{c}](x)$
(25) $\int d x[\gamma \square \bar{C}](x)$
(26) $\int d x\left[\gamma N_{3}\left[\bar{e} \varphi_{1}\right]\right](x)$
$(27) \int d x\left[\gamma N_{3}\left[-\varphi_{1}^{2}\right]\right](x)$
(28) $\int d x\left[\gamma N_{3}\left[\bar{e} \varphi_{2}^{2}\right]\right](x)$
(29) $\int d x\left[\gamma N_{3}\left[\bar{e} A_{\mu} A_{\mu}\right]\right](x)$

$$
\begin{equation*}
(30,31,32) \quad \int d x\left[\beta_{i} N_{4}\left[A_{\mu} \bar{c} \partial_{\mu} \bar{c}\right]\right](x) \tag{AVII,9}
\end{equation*}
$$

After elimination of the $\Delta_{i}^{\prime} s$ which are native variations, one is left with an $\alpha$, including source terms such that only $\Delta_{21}, \Delta_{22}, \Delta_{23}$ and a linear combination of $\Delta_{30}, \Delta_{31}, \Delta_{32}$, namely: $\Delta_{33}$

$$
=\vec{b} \int d x\left[\vec{\beta} N_{4}\left[A_{\mu} \bar{e} \partial_{\mu} \bar{e}\right]\right]^{\prime}(x) \quad \text { remain on the right hand side of the }
$$

Slavnov identity which reads :

$$
\partial \not Z^{c}=\left(c_{21} \Delta_{22}+c_{22} \Delta_{22}+c_{23} \Delta_{23}+c_{33} \Delta_{33}\right) z^{c}
$$

(AVII, 10)
Now recall that is the naive Slavnov identity associated with the Slavnov transformation we started with, hence $\vec{a} \cdot \vec{b}=0$
Now compute $\&^{2} \geq$, which because of this condition has the same form as the $\phi \pi$ equation of mon integrated through $\bar{\varepsilon}$.
We have:

$$
g^{2} z^{c}=\delta\left[c_{21} \Delta_{21}+c_{22} \Delta_{22}+c_{23} \Delta_{23}+c_{33} \Delta_{33}\right] z^{c}
$$

The same argument as before shows that $\delta^{2} Z^{c}$ has coefficients identical with those occuring in the $\phi \pi$ equation of motion, except for the mass term, and that

$$
\begin{equation*}
c_{21}=e_{22}=e_{23}=c_{33}=0 \tag{AVII,12}
\end{equation*}
$$

* If a monomial is of the form $\varepsilon M(\varphi)$ where $\varepsilon$ is an external field co which dimension $d$ was assigned, $N_{4}[\varepsilon M(\varphi)]$ means $\varepsilon N_{4-d}[M(\varphi)]$.

At this point the Lagrangian depends on 24 parameters since 28 relations wert imposed on the initial 52 parameters. Together with the $1 / 4$ independent parameters of the Slavnov identity we have 38 parameters which can be fixed by the 9 normalization conditions in Eq (31) ${ }^{x}$ together with 26 others fixing tine couplings with the external fields $\mathbf{K K}$. It is a matter of routine to verity that the corresponding system is soluble the condition $\vec{d} \cdot \vec{b}=0$ being preserver Three parameters are then left free $: l_{2}, Q, \sigma$. The gauge parameter $\sigma$ could be fixed by imposing an extra normalization condition on $\Gamma_{\varphi_{1}}^{2} \varphi_{2}^{2}$ We now extend the proof of the gauge invariance of the Scattering operator In order to do so, we shall decompose again the insertion $\Delta_{\lambda}$ generating ar infinitesimal variation of the gauge parameter $\lambda$ according to

$$
\begin{equation*}
\Delta_{\lambda}=\hat{\Delta}_{\lambda}+\Delta_{\lambda}^{s} \tag{AVIT}
\end{equation*}
$$

and we shall show that it is possible to choose the two insertions $\hat{\Delta}_{\lambda}$ and satisfying the same requirements as in chapter III. (Eq. (68) and Eq (73))
First of all, let us write Eq(AVII, 6) in the form.
$\delta_{\sigma} z^{c} \equiv\left\{\sum_{0}^{g} i c_{i} s_{i}+\int d x\left[\gamma \vec{b} \delta_{\vec{\beta}}+\vec{d} \cdot \vec{\beta} \delta_{\tau}\right](x)\right\} z^{c}$
(AVID. 14
the first six $\mathcal{B}_{i}^{\prime \prime}$ 's are listed in Eq. (76) the remaining four are:

$$
\begin{align*}
& \delta_{6}=\int d x\left[\xi \delta_{\gamma}\right](x) \\
& \delta_{7}=\int d x\left[\gamma \square \delta_{\xi}\right](x) \\
& \delta_{g}=\int d x\left[\gamma \delta_{\xi}\right](x)  \tag{AVII15}\\
& \delta_{g}=\int d x\left[\gamma \delta_{\eta}\right](x)
\end{align*}
$$

* Using the same kind of arguments as in Appendix III it can be shown that the condition given in Eq( 31,8 ) is a suitable normalization condition and that che mass term in the $\phi \pi$ equation of motion has the same coefficient as the corresponding term in $\mathcal{H}^{2} z^{c}$.
MK The simplest additional normalization conditions are:

$$
\begin{aligned}
& z_{1}=z_{2}=a=B_{11}=B_{22}=B_{33}=Q_{4}=1 \\
& z_{1}^{\prime}=Q_{2}=Q_{3}=Q_{5}=\vec{\mu}=\vec{v}=\vec{W}=B_{i \neq j}=0
\end{aligned}
$$

The derivative of $\delta_{\sigma}$ with respect to the parameter $\lambda$ is obtained by differentiating the $\sigma_{i}^{\prime} s$ and the vectors $\vec{b}$ and $\vec{d}$, since we know that $\vec{b} \cdot d=0$ (Eq(AVII, 7)) independently of $\lambda$, we have the equation :

$$
\begin{equation*}
\vec{d} \cdot \partial_{\lambda} \vec{b}+\vec{b} \partial_{\lambda} \vec{A}=0 \tag{AVII,16}
\end{equation*}
$$

We can parametrize $\partial_{\lambda} \vec{b}$ and $\partial_{\lambda} \vec{d}$ by introducing the two cartesian triplets:

$$
\begin{align*}
& \vec{b}, \vec{b}_{1}, \vec{b}_{2}  \tag{4yty,37}\\
& \vec{a}, \vec{a}_{1}, \vec{a}_{2}
\end{align*}
$$

in the form: $\overrightarrow{\partial_{\lambda}} \vec{b}=\sum_{i=1,2} x_{i}^{(\lambda)} \vec{d}_{i}+z^{(\lambda)} b^{2} \vec{d}$

$$
\begin{equation*}
\lambda_{\lambda} \vec{d}=\sum_{i=1,1 / 2}^{i=1, y_{i}} y^{(\lambda)} \vec{b}_{i}-z^{(\lambda)} d^{2} \vec{b} \tag{A,1,18}
\end{equation*}
$$

Thus we have to find $=1,2$ non physical $\hat{\Delta}_{\lambda}$ satisfying the equation:

$$
i_{i}\left[\hat{\Delta} \lambda, s_{\sigma}\right]=\sum_{i} i \partial_{\lambda} c_{i}^{(\lambda)} s_{i}+\int d x\left\{\sum_{i=1,2} x_{i}^{(\lambda)} \gamma \vec{d}_{i} \delta_{\beta}\right.
$$

$$
\left.+\sum_{i=1,2} y_{i}^{(\lambda)} \vec{b}_{i} \cdot \vec{\beta}_{\lambda} \delta_{\tau}+z^{(\lambda)}\left(b^{2} \gamma \vec{d} \cdot \delta_{\vec{\beta}}-d^{2} \vec{b} \cdot \vec{\beta} \delta_{\tau}\right)\right\}(x)
$$

The insertion $\hat{\Delta}_{\lambda}$ is a linear combination of a basis of covariant non physical insertions which can be found as follows.
First we introduce, in analogy with Eq. 78 ) three operators $Q_{i}, \varepsilon$
with $\delta_{g_{6}}=\delta_{\gamma}$. the same construction as in Chapter III we get three insertions $\Delta_{i}^{0}$ of covariances $C_{i} S_{i} \quad(i=4,5,6)$.
Then using the generalized action principle ${ }^{(6)}$ we can complete the basis of covariant non physical insertions as indicated in table (AVII, 1)

$$
\begin{aligned}
& \text { Insertion } \\
& \Delta \eta_{\eta_{2}}=\frac{\hbar}{l} \int d x\left[\eta_{2} \delta_{\eta_{2}}\right](x) \\
& \Delta_{\eta_{1}}=\frac{t}{l} \int d x\left[\eta_{1} g_{\xi}\right](x) \\
& \Delta_{q_{1}}=\frac{t_{i}}{i} \int d x\left[q_{i} F_{\xi}^{\prime}\right](x) \\
& \Delta_{\beta}=\frac{\hbar}{i b^{2}} \int d x\left[\vec{b} \vec{\rho} \square_{\xi}\right](x) \\
& \Delta_{\beta}^{\prime}=\frac{a}{i b^{2}} \int d x\left[b \cdot \vec{\beta} d_{\xi}\right](x) \\
& \Delta_{\beta}^{n}=\frac{\hbar}{i b^{2}} \int d x\left[\vec{b} \cdot \vec{p} \delta_{q_{1}}\right](x) \\
& \Delta_{\beta^{2}}^{i}=\frac{\hbar}{i b^{2}} i \int d x\left[\vec{b} \cdot \vec{\beta} \cdot \vec{d}_{i} \cdot \delta_{\beta}\right](x) \\
& \Delta_{\beta^{2}}^{\lambda}=\frac{t}{i d^{2}} \int d x\left[\vec{b}_{i} \cdot \vec{\beta} \vec{d} \delta_{\vec{\beta}}\right](x) \\
& \Delta_{\beta^{2}}^{r_{i}}=\frac{\pi}{i} \int d x\left[\vec{b} \cdot \vec{\beta} \vec{d} \cdot \delta_{\vec{\beta}}\right](x)
\end{aligned}
$$

It is evident that one can find a particular solution of Eq. (AVII, 19) as a linear combination of these insertions and of the three In the same way one can get other non physical insertions which are listed in table (AVII-II)

## Insertions

$\Delta_{l}^{0}=\int d x J_{l}(x)$
$\Delta_{c}=\frac{t}{i} \int d x\left[\xi \delta_{\xi}\right](x)$
$\Delta_{\varphi_{2}}=\frac{\hbar}{i} \int d x\left[J_{2} \delta_{J_{2}}\right](x)$
$\Delta_{\gamma}=\frac{\hbar}{i} \int d x\left[\gamma \delta_{\gamma}\right](x)$
$\Delta_{\gamma}^{\prime}=\frac{\hbar}{e} \int d x\left[\gamma \delta_{J_{2}}\right](x)$
$\Delta_{\gamma}^{\prime \prime}=\frac{\pi}{i} \int d x\left[Y \partial_{\mu} \delta_{J_{\mu}}\right](x)$
$\Delta_{\beta}^{i}=\frac{\hbar}{i} \int d x\left[\vec{b}_{i} \cdot \delta_{\beta} \square \delta_{\xi}\right](x)$
$\Delta_{\beta}^{1 i}=\frac{\hbar}{i} \int d x\left[\vec{b}_{i} f_{\vec{\beta}} \quad \xi\right](x)$
$\Delta_{\beta}^{U i}=\frac{\pi}{i} \int d x\left[\vec{b}_{i} \cdot \delta_{\vec{\beta}} \delta_{\eta_{\perp}}\right](x)$
$\Delta_{3^{2}}^{i j}=\frac{t}{i} \int d x\left[\overrightarrow{b_{i}} \cdot \vec{\beta} \quad \vec{d} \cdot \delta_{\vec{\beta}}\right](x)$
$\Lambda_{\tau}=\frac{t_{i}}{i} \int d x i \tau \delta_{\tau} J(x)$

$$
\Delta_{\gamma^{2}}=\int d x \gamma^{2}(x)
$$

$$

It is clear that combining litearly the insertions listed in Table (AVII.II) with those previously considered we obtain 18 symetrical non physical insertions; in fact, because of the orthogonality condition Eq(AVII, 7) $\vec{b}$ is a linear combination of the $\vec{J}_{i}^{\prime} \dot{s}$ and $\vec{d}$ of the $\vec{b}_{i}^{\prime} \lambda(i=1,2)$.
Now, following the same procedure as in Chapter III, we couplete the construction of $\Delta_{\lambda}$ by studying a basis of symmetrical insertions $\Delta^{5}$ Since we know that, given the Slavnov identity, the complete lagrangian (Eq(AVII,5)) depends on 24 parameters, ( 6 of them fixing the propagators and the couplings of the quantized fields, and 1 specifying the external field dependence) it follows that there are 24 independent symmetrical insertions We have already constructed 10 independent $\Delta^{S^{\prime}} \Delta$ which are non physical. Thus to complete the proof of gauge invariance we have to find six symetrical insertions satisfying Eq. (70) . Five of them are determined by the independent terms of the tree approximation lagrangian (Eq(AVII, 2) excluding $\frac{g^{2}}{2}+c m e$ The sixth one is the analog of $\Delta_{6}^{5} \quad\left(E_{q}(98)\right)$. They verify $\mathbf{B q}_{\boldsymbol{q}}(70)$ as can be seen in the tree approximation
