# SOME REMARKS ON QUADRATIG PROGRAMIMING WITH 0-1 VARIABLES 

by Peter L. Hammer ( ${ }^{1}$, and Abraham A. Rubin ( ${ }^{2}$ )

#### Abstract

The aim of this paper is to show that (1) every bivalent ( 0,1 ) quadratic programming problem is equivalent to one having a positive (negative) semi-definite matrix in the objective function; (2) to establish conditions for different classes of local optimality ; (3) to show that any problem of bivalent ( 0,1 ) programming is equivalent (a) to the problem of minimizing a real valued function, partly in $(0,1)$, and partly in nonnegative variables, (b) to the problem of finding the minimax of a real valued function in bivalent $(0,1)$ variables.

## INTRODUCTION

Numerous problems in various fields of operations research (investment problems, graphs; etc.) lead naturally to problems of quadratic programming with variables which can take on only the values 0 and 1.

The available methods for solving mathematical programs in $0-1$ variables, are either dealing only with the linear case (and hence unapplicable for our problems), or dealing with the most general cases (and hence not taking into account the particularities of a quadratic program). Specific methods for the solution of quadratic bivalent programs have been studied by H. P. Kunzi and W. Oettli [4], V. Ginsburgh and A. Van Peeterssen [2] and the present authors [5].

Our aim in this paper is to study some general properties of quadratic $0-1$ programs. We shall deal here with :
a) The relationship between a quadratic $0-1$ program and the associated continuous program;
b) Conditions for different types of local optima ;
c) Possibilities of reducing a quadratic program to
c.1) an unconstrained quadratic minimization problem,
$c .2$ ) an unconstrained quadratic minimax problem.

[^0]
## $*^{*} *$

A Boolean pariable $x_{i}$ is a variable which takes its values from the two element Boolean algebra $B_{2}=\{0,1\}$.

A vector $X$ with $n$ Boolean components will be called a Boolean vector. The set of these vectors will be denoted by $B_{2}^{n}$.

A mapping $f(X)$ from $B_{2}^{n}$ into the field $R$ of reals will be called a pseudo-Boolean function.

We define the distance $d(X, Y)$ of two vectors $X$ and $Y$ belonging to $B_{2}^{n}$ by putting :

$$
\begin{equation*}
d(X, Y)=\sum_{i=1}^{n}\left(x_{i}-y_{i}\right)^{2} \tag{0.1}
\end{equation*}
$$

$d(X, Y)$ represents the number of different components of $X$ and $Y$.
We define the $k$-neighbourhood $W_{k}(X)$ of $X$ in $B_{2}^{n}$ as the set of those vectors $Y$ belonging to $B_{2}^{n}$ which are at distance $k$ from $X$ :

$$
\begin{equation*}
W_{k}(X)=\left\{Y \in B_{2}^{n}, d(X, Y)=k\right\} \tag{0.2}
\end{equation*}
$$

$f\left(X^{*}\right)$ is a (globally) minimizing point of the pseudo-Boolean function $f(X)$ if :

$$
\begin{equation*}
f\left(X^{*}\right) \leqslant f(X) \text { for any } X \in B_{2}^{n} \tag{0.3}
\end{equation*}
$$

$X^{*}$ is a locally minimizing point of $f$ if :

$$
\begin{equation*}
f\left(X^{*}\right) \leqslant f(X) \text { for any } X \in W_{1}\left(X^{*}\right) \tag{0.4}
\end{equation*}
$$

and more generally $X^{*}$ will be a $k$-minimizing point of $f$ if :

$$
\begin{equation*}
f\left(X^{*}\right) \leqslant f(X) \text { for any } X \in W_{k}\left(X^{*}\right) \tag{0.5}
\end{equation*}
$$

Given a real valued $n$ by $n$ matrix $\tilde{Q}=\left(\tilde{q}_{i j}\right)$ and a real valued $n$ vector $p$ we define the pseudo Boolean quadratic function $f(X)$ as :

$$
\begin{equation*}
f(X)=X^{\prime} \tilde{Q} X+p^{\prime} X \tag{0.6}
\end{equation*}
$$

Remarking that $x_{i}^{2}=x_{i}$ for every $i, i=1, \ldots, n$ we add the component $p_{i}$ of the vector $p$ to the $i$-th diagonal element of the matrix $\tilde{Q}$. Let us denote by $Q=\left(q_{i j}\right)$ the new matrix defined by:

$$
q_{i j}= \begin{cases}\tilde{q}_{i j} & i \neq j \\ \tilde{q}_{i j}+p_{i} & i=j\end{cases}
$$

From now on we will represent a pseudo-Boolean quadratic function simply by :

$$
\begin{equation*}
f(X)=X^{\prime} Q X \tag{0.7}
\end{equation*}
$$

The matrix $Q$ will always be assumed to be symmetric. otherwise as $X^{\prime} Q X=\frac{1}{2} X^{\prime}\left(Q+Q^{\prime}\right)$ the matrix $\frac{1}{2}\left(Q+Q^{\prime}\right)$ is symmetric, showing that our assumption is not restrictive.

## 1. THE ASSOCIATED CONTINUOUS PROGRAM

By a problem of quadratic pseudo-Boolean programming under linear constraints we shall mean the problem of minimizing

$$
X^{\prime} Q X
$$

subject to

$$
\begin{equation*}
A X \leqslant b \tag{1.1}
\end{equation*}
$$

and to

$$
\begin{equation*}
X \in B_{2}^{n} \tag{1.2}
\end{equation*}
$$

where $A$ is a given $m \times n$ matrix, $Q$ is a given symmetric $n \times n$ matrix, $b$ is a given $m$-vector, and $X$ is an $n$-vector to be determined.

This problem will be called Problem I. To Problem I we associate the following Problem II :

Minimize

$$
X^{\prime} Q X
$$

subject to

$$
\begin{equation*}
A X \leqslant b \tag{1.3}
\end{equation*}
$$

and to

$$
\begin{equation*}
0 \leqslant x_{j} \leqslant 1 \quad(j=1, \ldots, n) \tag{1.4}
\end{equation*}
$$

Numerous procedures are available for solving Problem II when $Q$ is a positive semidefinite matrix (see, e.g. [1], [6], etc.).

Obviously, by a rounding procedure we can obtain from the optimal solution of Problem II a certain «approximation» of the optimal solution of Problem I.

In order to make use of this remark, we have to solve Problem II ; the simplest way seems to utilize the following :

Theorem 1. Given a symmetric $n \times n$ matrix $Q$, there exists a positive definite $n \times n$ matrix $R$ and an $n$-sector $d$ such that if

$$
\begin{aligned}
& f(X)=X^{\prime} Q X \\
& g(X)=X^{\prime} R X+d X
\end{aligned}
$$

then,

$$
f(X)=g(X) \text { for every } X \in B_{2}^{n}
$$

Proof. Let $\gamma$ be an arbitrary real number, and let

$$
g_{\gamma}(X)=X^{\prime} Q X+\gamma \sum_{i=1}^{n}\left(x_{i}^{2}-x_{i}\right)
$$

or

$$
g_{\gamma}(X)=X^{\prime}(Q+\gamma I) X-\gamma \sum_{i=1}^{n} x_{i}
$$

From the fact that $x_{i}^{2}=x_{i}$ for any $x_{i} \varepsilon B_{2}$, it follows that $f(X)=g_{\gamma}(X)$ for any $X \in B_{2}^{n}$.
$Q$ being a symmetric matrix, its eigen-values are reals. Let $\lambda$ denote the smallest of these eigen-values. The smallest eigen-value of $Q+\gamma I$ will hence be $\lambda+\gamma$. Choosing $\gamma$ such that $\lambda+\gamma$ should be positive, we assure the positive definiteness of $Q+\gamma I$, thus proving the theorem.

In order to make a reasonably good choice of the $\gamma$, let us remark the followings. If $\gamma_{1}$ and $\gamma_{2}$ are two reals ( $\gamma_{1}<\gamma_{2}$ ) satisfying the conditions $\lambda+\gamma_{n}>0(h=1,2)$, and if $P-h$ denotes the problem of minimizing $g_{\gamma_{n}}$ under constraints (1.3) and (1.4) (assumed to be consistent), then let us denote by $X_{h}$ the optimal solution of $P-h$. Let us further denote the center of the hypercube $B_{2}^{n}$ by $C=\left(\frac{1}{2}, \frac{1}{2}, \cdots, \frac{1}{2}\right)$, and let the distance $d\left(V_{1}, V_{2}\right)$ between two real vectors $V_{1}=\left(V_{11}, \ldots, V_{1 n}\right)$ and $V_{2}=\left(V_{21}, \ldots\right.$, $\left.V_{2 n}\right)$ be

$$
d\left(V_{1}, V_{2}\right)=\sum_{i=1}^{n}\left(V_{1 i}-V_{2 i}\right)^{2}
$$

The following result holds :
Theorem 2. If $\gamma_{1}<\gamma_{2}$ then $d\left(X_{1}, C\right)>d\left(X_{2}, C\right)$.
Proof. From the fact that $X_{1}$ is an optimal solution of $P-1$, and $X_{2}$ is a feasible solution of the same problem, it follows that

$$
g_{1}\left(X_{1}\right) \leqslant g_{1}\left(X_{2}\right) .
$$

Analogously,

$$
g_{2}\left(X_{2}\right) \leqslant g_{2}\left(X_{1}\right)
$$

These relations can be rewritten as

$$
\begin{align*}
& X_{1}^{\prime} Q X_{1}+\gamma_{1} \sum_{i=1}^{n}\left(x_{1 i}^{2}-x_{1 i}\right) \leqslant X_{2}^{\prime} Q X_{2}+\gamma_{1} \sum_{i=1}^{n}\left(x_{2 i}^{2}-x_{2 i}\right)  \tag{1.5}\\
& X_{2}^{\prime} Q X_{2}+\gamma_{2} \sum_{i=1}^{n}\left(x_{2 i}^{2}-x_{2 i}\right) \leqslant X_{1}^{\prime} Q X_{1}+\gamma_{2} \sum_{i=1}^{n}\left(x_{1 i}^{2}-x_{1 i}\right) \tag{1.6}
\end{align*}
$$

Adding (1.5) and (1.6) we get

$$
\left(\gamma_{1}-\gamma_{2}\right) \sum_{i=1}^{n}\left(x_{1 i}^{2}-x_{1 i}\right) \leqslant\left(\gamma_{1}-\gamma_{2}\right) \sum_{i=1}^{n}\left(x_{2 i}^{2}-x_{2 i}\right)
$$

As $\gamma_{1}<\gamma_{2}$, it follows that

$$
\begin{equation*}
\sum_{i=1}^{n}\left(x_{1 i}^{2}-x_{1 i}\right) \geqslant \sum_{i=1}^{n}\left(x_{2 i}^{2}-x_{2 i}\right) . \tag{1.7}
\end{equation*}
$$

Hence

$$
\sum_{i=1}^{n}\left(x_{1 i}-\frac{1}{2}\right)^{2} \geqslant \sum_{i=1}^{n}\left(x_{2 i}-\frac{1}{2}\right)^{2}
$$

or

$$
\begin{equation*}
d\left(X_{1}, C\right) \geqslant d\left(X_{2}, C\right) \tag{1.8}
\end{equation*}
$$

proving the theorem.
It follows from Theorem 2, that in order to get a good starting solution of $P I$ from the rounded optimal solution of $P I I$ it is advisable to choose $\gamma$ as small as possible.

## 2. CONDITIONS FOR $\boldsymbol{k}$-MINIMALITY

A vector $X$ is a $k$-minimizing point for the function $f$ if :

$$
\begin{equation*}
f(X) \leqslant f(Y) \quad \text { for any } \quad Y \varepsilon W_{k}(X) \tag{2.1}
\end{equation*}
$$

Let us denote by $J$ the set of the indices of the $k$ differing components of $X$ and $Y$ :

$$
\begin{array}{ll}
x_{i}=y_{i} & i \notin J \\
x_{i}=1-y_{i} & i \in J  \tag{2.3}\\
J \subset\{1, \ldots, n\} & \text { and }|J|=k
\end{array}
$$

Condition (2.1) is expressed by

$$
\begin{equation*}
f(X)-f(Y)=\sum_{i=1}^{n} \sum_{j=1}^{n} q_{i j} x_{i} x_{j}-\sum_{i=1}^{n} \sum_{j=1}^{n} q_{i j} y_{i} y_{j} \leqslant 0 \tag{2.4}
\end{equation*}
$$

Using (2.2) and (2.3) we get

$$
\begin{align*}
f(X)-f(Y) & =\sum_{i \neq J} \sum_{j \neq J} q_{i j} x_{i} x_{j}-\sum_{i \neq J} \sum_{j \neq J} q_{i j} y_{i} y_{j} \\
& +\sum_{i \in J} x_{i} \sum_{j \neq J} 2 q_{i j} x_{j}+\sum_{i \in J} \sum_{j \in J} q_{i j} x_{i} x_{j} \\
& -\sum_{i \in J} y_{i} \sum_{j \neq J} 2 q_{i j} y_{j}-\sum_{i \in J} \sum_{j \in J} q_{i j} y_{i} y_{j} \tag{2.5}
\end{align*}
$$

or,

$$
\begin{equation*}
f(X)-f(Y)=\sum_{i \in J}\left(2 x_{i}-1\right)\left[\sum_{j \neq J} 2 q_{i j} x_{j}+\sum_{j \in J} q_{i j}\right], \tag{2.6}
\end{equation*}
$$

Hence, $X$ is a $k$-minimizing point for the function $f$ iff for every set of indices $J$, such that $|J|=k$, the following relation holds :

$$
\begin{equation*}
\sum_{i \in J}\left(2 x_{i}-1\right)\left[\sum_{j \notin J} 2 q_{i j} x_{j}+\sum_{j \in J} q_{i j}\right] \leqslant 0 \tag{2.7}
\end{equation*}
$$

In particular
for $J=\{1,2, \ldots, n\},(2.7)$ simplifies to

$$
\begin{equation*}
\sum_{i=1}^{n}\left(2 x_{i}-1\right)\left(\sum_{j=1}^{n} q_{i j}\right) \leqslant 0 ; \tag{2.8}
\end{equation*}
$$

for $J=\{l\},(2.7)$ simplifies to

$$
\begin{equation*}
\left(2 x_{i}-1\right)\left(\sum_{j \neq l} 2 q_{l} x_{j}+q_{n}\right) \leqslant 0 ; \tag{2.9}
\end{equation*}
$$

for $J=\{1,2, \ldots, n\},-\{l\}(2.7)$ simplifies to

$$
\begin{equation*}
\sum_{j \neq l}\left(2 x_{j}-1\right)\left(2 q_{l j} x_{t}+\sum_{j \neq l} q_{t j}\right) \leqslant 0 \tag{2.10}
\end{equation*}
$$

Remark. We point out that a 1-minimizing and 2-minimizing point $X^{*}$ is not necessarily a globally minimizing point. Consider for this, the following example in $B_{2}^{3}$ :

Let

$$
Q=\left(\begin{array}{rrr}
5 & 0 & -3 \\
0 & 5 & -3 \\
-3 & -3 & 5
\end{array}\right)
$$

The point ( $1,1,1$ ) is both 1 -minimizing and 2 -minimizing, but it is not globally minimizing; the globally minimizing point is $(0,0,0)$, as it can be seen from Table 1.

Table. 1

| $x_{1}$ | $x_{2}$ | $x_{3}$ | $X^{\prime} Q X$ |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 |
| 1 | 0 | 0 | 5 |
| 0 | 1 | 0 | 5 |
| 0 | 0 | 1 | 5 |
| 1 | 1 | 0 | 10 |
| 1 | 0 | 1 | 4 |
| 0 | 1 | 1 | 4 |
| 1 | 1 | 1 | 3 |

## 3. MINIMIZATION UNDER CONSTRAINTS

The problem (III) we shall consider in his section is the following :
Minimize : $f(X)=X^{\prime} Q X$
under the following constraints :

$$
\begin{array}{ll}
\varphi_{j}(X) \leqslant 0 & j=1, \ldots, m  \tag{3.1}\\
\varphi_{j}(X)=0 & j=m+1, \ldots, l
\end{array}
$$

$X \in B_{2}^{n} ;$
here $\varphi_{j}(X)$ are pseudo-Boolean functions of $X$. We shall assume that these functions $\varphi_{j}(X)$ are integer valued. As $X$ has to satisfy the set of constrains (3.1), we have to define the concept of locally minimizing points of a pseudo-Boolean function under pseudo-Boolean constraints.
$X^{*}$ is a locally minimizing point for the function $f(X)$ under the set of constraints (3.1.) if

1) $X^{*}$ fulfills the set of constraints (3.1.)
2) for every $Y \& W_{1}\left(X^{*}\right)$, either $f\left(X^{*}\right) \leqslant f(Y)$ or $Y$ violates at least one of the constraints ( 3.1 ) $(j=1, \ldots, l)$.
A. Introducing slack pariables.

We introduce the slack variables $u_{j}(j=1, \ldots, m)$, and reformulate (IV) the program (III) :

Minimize $f(X)=X^{\prime} Q X$
so that

$$
\begin{array}{ll}
\varphi_{j}(X)+u_{j}=0, & j=1, \ldots, m \\
\varphi_{j}(X)=0, & j=m+1, \ldots, l  \tag{3.2}\\
X \in B_{2}^{n} ; u_{j} \geqslant 0 & j=1, \ldots, m
\end{array}
$$

We can use "Lagrangean multipliers» (as defined in [3]) and formulate the program as one without constraints. For this sake, let us denote by $B^{+}$and $B^{-}$, an upper and a lower bound of $f(x)$ in $B_{2}^{n}$ (for example the sum of all its positive and all its negative coefficients). We have :

Theorem 3. (See [3]).
( $\alpha$ ) If $X^{*}=\left(x_{1}^{*} \ldots, x_{n}^{*}\right)$, is an optimal solution of problem (III), then there exists a vector $U^{*}=\left(u_{1}^{*}, \ldots, u_{m}^{*}\right)$, such that $\left(X^{*}, U^{*}\right)$ is an optimal solution of the following problem ( V ):

Minimize

$$
\begin{gather*}
F\left(x_{1}, \ldots, x_{n}, u_{1}, \ldots, u_{m}\right)=f\left(x_{1}, \ldots, x_{n}\right) \\
+\left(B^{+}-B^{-}+1\right)\left(\sum_{j=1}^{m}\left(\varphi_{j}(X)+u_{j}\right)^{2}+\sum_{j=m+1}^{1} \varphi_{j}^{2}(X)\right) ;  \tag{3.6}\\
x_{i} \in\{0,1\} ; \quad i=1, \ldots, n ; \quad u_{j} \geqslant 0, \quad j=1, \ldots, m .
\end{gather*}
$$

( 3 ) If $\left(X^{*}, U^{*}\right)$ is an optimal solution of problem $(V)$ and $F\left(x_{1}^{*}, \ldots\right.$, $\left.x_{n}^{*}, u_{1}^{*}, \ldots, u_{m}^{*}\right) \leqslant B^{+}$, then the constraints (3.1.) are consistent and $X^{*}$ is an optimal solution of problem (III).
( $\gamma$ ) If $\left(X^{*}, U^{*}\right)$ is an optimal solution of problem (V), and $F\left(x_{1}^{*}, \ldots\right.$, $\left.x_{n}^{*}, u_{1}^{*}, \ldots, u_{m}^{*}\right)>B^{+}$, then the constraints (3.1) are inconsistent.

Proof. Let us first notice that

$$
\begin{equation*}
B^{-} \leqslant f(X) \leqslant B^{+} \tag{3.7}
\end{equation*}
$$

( $\alpha$ ) Given an opimal solution $X^{*}$ of problem (III), we have :

$$
\begin{array}{ll}
\varphi_{j}\left(X^{*}\right)=0 & j=m+1, \ldots, l \\
\varphi_{j}\left(X^{*}\right) \leqslant 0 & j=1, \ldots, m
\end{array}
$$

We define the vector $U^{*}$ by

$$
u_{j}^{*}=-\varphi_{j}\left(X^{*}\right) \geqslant 0 \quad j=1, \ldots, m
$$

Let us suppose that there exists a vector $\left(Y^{*}, V^{*}\right),\left(Y^{*} \in B_{2}^{n} ; V^{*} \geqslant 0\right)$ such that

$$
\begin{equation*}
F\left(Y^{*}, V^{*}\right)<F\left(Y^{*}, U^{*}\right) \tag{3.8}
\end{equation*}
$$

It follows that $Y^{*}$ fulfils the system (3.1). Indeed, if not, then there exists an index $j_{0}$ such that either

$$
\begin{equation*}
j_{0} \in(1, \ldots, m) \quad \text { and } \quad \varphi_{j 0}\left(Y^{*}\right) \geqslant 1 \tag{3.9}
\end{equation*}
$$

or

$$
\begin{equation*}
j_{0} \in(m+1, \ldots, l) \quad \text { and } \quad \varphi_{j 0}\left(Y^{*}\right) \neq 0 \tag{3.10}
\end{equation*}
$$

In the first case, $\varphi_{j 0}\left(Y^{*}\right) \geqslant 1$ and $v_{j 0}^{*} \geqslant 0$ imply

$$
\left(\varphi_{j 0}\left(Y^{*}\right)+v_{j 0}^{*}\right)^{2} \geqslant 1 .
$$

In the second case, we see that

$$
\begin{equation*}
\varphi_{j 0}^{2}\left(Y^{*}\right) \geqslant 1 \tag{3.11}
\end{equation*}
$$

In both cases we deduce that

$$
\begin{equation*}
\sum_{j=1}^{m}\left(\varphi_{j}\left(Y^{*}\right)+v_{j}^{*}\right)^{2}+\sum_{j=m+1}^{l} \varphi_{j}^{2}\left(Y^{*}\right) \geqslant 1 \tag{3.12}
\end{equation*}
$$

and

$$
\begin{equation*}
F\left(Y^{*}, V^{*}\right) \geqslant f\left(Y^{*}\right)+B^{+}-B^{-}+1 \geqslant B^{+}+1 \tag{3.13}
\end{equation*}
$$

On the other hand

$$
\begin{equation*}
F\left(X^{*}, U^{*}\right)=f\left(X^{*}\right) \leqslant B^{+} \tag{3.14}
\end{equation*}
$$

From (3.13) and (3.14) we get

$$
\begin{equation*}
F\left(X^{*}, U^{*}\right)<F\left(Y^{*}, V^{*}\right) \tag{3.15}
\end{equation*}
$$

which contradicts (3.8.) Hence $Y^{*}$ fulfils the constraints (3.1).

As above we can also deduce that
hence :

$$
v_{j}^{*}=-\varphi_{j}\left(Y^{*}\right), \quad j=1, \ldots, m
$$

$$
\begin{equation*}
F\left(Y^{*}, V^{*}\right)=f\left(Y^{*}\right) \tag{3.16}
\end{equation*}
$$

From (3.16) and (3.8) we deduce that

$$
\begin{equation*}
F\left(Y^{*}, V^{*}\right)=f\left(Y^{*}\right)<F\left(X^{*}, U^{*}\right)=f\left(X^{*}\right) \tag{3.17}
\end{equation*}
$$

or

$$
f\left(Y^{*}\right)<f\left(X^{*}\right)
$$

contradicting the fact that $X^{*}$ is an optimal solution of problem (III).
( $\beta$ ) Conversely, let $\left(X^{*}, U^{*}\right)$ be an optimal solution of problem (V). It follows then, that $X^{*}$ satisfies the constraints (3.1) and

$$
\begin{equation*}
u_{j}^{*}=-\varphi_{j}\left(X^{*}\right), \quad j=1, \ldots, m \tag{3.19}
\end{equation*}
$$

because if not, we could reason as above deducing

$$
\begin{equation*}
F\left(X^{*}, U^{*}\right) \geqslant f\left(X^{*}\right)+B^{+}-B^{-}+1>B^{+} \tag{3.20}
\end{equation*}
$$

Now it can be easily seen that $X^{*}$ is an opimal solution of problem (III).
( $\gamma$ ) If the constraints (3.1) are consistent, let $Y^{*}$ be a vector satisfying them and let us put

$$
\begin{equation*}
\left(\varphi_{j}=-\varphi_{j}\left(Y^{*}\right) \quad j=1, \ldots, m\right. \tag{3.21}
\end{equation*}
$$

Hence,

$$
\begin{equation*}
F\left(Y^{*}, V^{*}\right)=f\left(Y^{*}\right) \leqslant B^{+} \tag{3.22}
\end{equation*}
$$

which contradicts the assumption ( $\gamma$ ).

$$
*^{*}{ }^{*}
$$

## B. Minimax formulation

Let us consider the following problem (VI) :
Find the minimum over all $X \in B_{2}^{n}$ of the maximum over all $V \in B_{2}^{m}$, of $F(X, V)$, where
$F(X, V)$

$$
\begin{equation*}
=f(X)+\left(B^{+}-B^{-}+1\right)\left(\sum_{j=1}^{m} v_{j} \varphi_{j}(X)+\sum_{j=m+1}^{l} \varphi_{j}^{2}(X)\right) \tag{3.23}
\end{equation*}
$$

and where

$$
\begin{equation*}
X=\left(x_{1}, \ldots, x_{n}\right) \in B_{2}^{n} \tag{3.24}
\end{equation*}
$$

$$
\begin{equation*}
V=\left(v_{1}, \ldots, v_{m}\right) \in B_{2}^{m} \tag{3.25}
\end{equation*}
$$

$\left.X^{*}, V^{*}\right)$ will be called a minimaxing point of problem (VI) if :

$$
\begin{array}{lll}
F\left(X^{*}, V^{*}\right) \geqslant F\left(X^{*}, V\right), & \text { for any } & V \in B_{2}^{m}  \tag{3.26}\\
F\left(X^{*}, V^{*}\right) \leqslant \underset{V \in B^{n_{2}}}{\operatorname{ax}} F(X, V), & \text { for any } & X \in B_{2}^{n}
\end{array}
$$

and ( $X^{*}, V^{*}$ ) will be called a locally minimaxing point of problem (VI) if :

$$
\begin{array}{lll}
F\left(X^{*}, V^{*}\right) \geqslant F\left(X^{*}, V\right), & \text { for any } & V \in B_{2}^{m}  \tag{3.27}\\
F\left(X^{*}, V^{*}\right) \leqslant \operatorname{Max}_{V \in B_{2}^{m}} F(X, V), & \text { for any } & X \in W_{1}\left(X^{*}\right)
\end{array}
$$

Theorem 4. Every pseudo-Boolean program under linear constraints is equivalent to a minimax problem without constraints. The relations between the optimizing points are the following:
( $\alpha$ ) If $X^{*}=\left(x_{1}^{*}, \ldots, x_{n}^{*}\right.$ is a globally minimizing point of problem (III), then there exists a $V^{*} \in B_{2}^{m}$ such that $\left(X^{*}, V^{*}\right)$ is a minimaxing point of problem (VI).
( $\beta$ ) If $\left(X^{*}, V^{*}\right)$ is a minimaxing point of problem (VI) and $F\left(X^{*}, V^{*}\right) \leqslant B^{+}$then $X^{*}$ is a globally minimizing point of problem (III).
$(\gamma)$ If $\left(X^{*}, V^{*}\right)$ is a minimaxing point of problem (VI), and $F\left(X^{*}, V^{*}\right)>B^{+}$then the constraints (3.1.) are inconsistent.
( $\delta$ ) If $X^{*}$, is a locally minimizing point of problem (III) then there exists $V^{*} \in B_{2}^{m}$, such that $\left(X^{*}, V^{*}\right)$ is a locally minimaxing point of problem (VI).
(ع) If $\left(X^{*}, V^{*}\right)$ is a locally minimaxing point of problem (VI) and

$$
F\left(X^{*}, V^{*}\right) \leqslant B^{+}
$$

then $X^{\star}$ is a locally minimizing point of problem (III).
Proof.
(a) If $X^{*}$ is a globally minimizing point of problem (III), then

$$
\begin{array}{ll}
\varphi_{j}\left(X^{*}\right) \leqslant 0 & j=1, \ldots, m \\
\varphi_{j}\left(X^{*}\right)=0 & j=m+1, \ldots, l \tag{3.30}
\end{array}
$$

Let us take $V^{*}$ such that
then,

$$
v_{j}^{*}=0, \quad j=1, \ldots, m
$$

,

$$
F\left(X^{*}, V^{*}\right)=\operatorname{Max}_{V \in B^{m_{2}}} F\left(X^{*}, V\right)
$$

and

$$
\begin{equation*}
F\left(X^{*}, V^{*}\right)=f\left(X^{*}\right) \tag{3.31}
\end{equation*}
$$

Let suppose that there exists a vector $Y \in B_{2}^{n}$ such that

$$
\begin{equation*}
\operatorname{Max}_{V} F(Y, V)<f\left(X^{*}\right) \tag{3.32}
\end{equation*}
$$

It follows from (3.32) that $Y$ fulfils the set of constraints (3.1). Indeed,
if not, then at least one constraint is violated. There exists either an index $j_{0} \in(1, \ldots, m)$ such that $\varphi_{j 0}(Y) \geqslant 1$ implying $\varphi_{j 0}=1$, and

$$
\begin{equation*}
v_{j 0} \varphi_{j 0}(Y) \geqslant 1, \tag{3.33}
\end{equation*}
$$

or an index $j_{0} \in(m+1, \ldots, l)$ such that $\varphi_{j 0}(Y) \neq 0$, implying

$$
\begin{equation*}
\varphi_{j 0}^{2}(Y) \geqslant 1 \tag{3.34}
\end{equation*}
$$

Every term of the sum

$$
\begin{equation*}
\sum_{j=1}^{m} v_{j} \varphi_{j}(Y) \tag{3.35}
\end{equation*}
$$

will be non-negative following the choice of $V$ :

$$
\begin{array}{lll}
\varphi_{j}(Y)<0 & \text { implies } & \left(\varphi_{j}=0\right. \\
\varphi_{j}(Y)>0 & \text { implies } & \left(\varphi_{j}=1\right. \\
\varphi_{j}(Y)=0 & & \left(\varphi_{j}\right. \text { free }
\end{array}
$$

From (3.33), (3.34) and (3.35) we get

$$
\begin{equation*}
\underset{V}{\operatorname{Max}} F(X, V) \geqslant f(Y)+B^{+}-B^{-}+1 \geqslant B^{+}+1 . \tag{3.36}
\end{equation*}
$$

From (3.31) and (3.36) we obtain

$$
\begin{equation*}
F\left(X^{*}, V^{*}\right)<\operatorname{Max}_{V} F(Y, V) \tag{3.37}
\end{equation*}
$$

which contradicts (3.32). Hence $Y$ fulfils the set of constraints (3.1).
As above, we deduce that

$$
\begin{equation*}
\underset{V}{\operatorname{Max}} F(Y, V)=f(Y) \tag{3.38}
\end{equation*}
$$

so that relation (3.32) becomes

$$
\begin{equation*}
f(Y)<f\left(X^{*}\right) \tag{3.39}
\end{equation*}
$$

contradicting the fact that $X^{*}$ is a minimizing point for problem (III).
( $\beta$ ) Conversely, let ( $X^{*}, V^{*}$ ) be a minimaxing point of problem (VI); then, $X^{*}$ satisfies the constraints (3.1). If not, we could reason as above deducing

$$
F\left(X^{*}, V^{*}\right)=\operatorname{ax}_{V} F\left(X^{*}, V\right) \geqslant f\left(X^{*}\right)+B^{+}-B^{-}+1>B^{+}
$$

Now it is obvious that $X^{*}$ is also an optimal solution of problem (III).
( $\gamma$ ) If the constraints (3.1) are consistent, let us denote by $Y$ a vector satisfying them. We get

$$
\begin{equation*}
\underset{V}{\operatorname{Max}} F(Y, V)=f(Y) \leqslant B^{+} \tag{3.40}
\end{equation*}
$$

which contradicts the assumption in ( $\gamma$ ).
$(\delta) X^{*}$ satisfies the constraints (3.1). Let us take $V^{*}$ such that $v_{j}^{*}=0$ ( $j=1, \ldots, m$ ) ; then,

$$
\begin{gather*}
F\left(X^{*}, V^{*}\right)=\operatorname{Max}_{V \in B^{n}{ }_{2}} F\left(X^{*}, V\right) \\
F\left(X^{*}, V^{*}\right)=f\left(X^{*}\right) \leqslant B^{+} \tag{3.41}
\end{gather*}
$$

For every $X \in W_{1}\left(X^{*}\right)$ one of the following alternatives holds :
(1) $X$ satisfies the contraints and

$$
\begin{equation*}
f\left(X^{*}\right) \leqslant f(X) \tag{3.42}
\end{equation*}
$$

It follows then, that

$$
\begin{equation*}
\underset{V}{\operatorname{Max}} F(X, V)=f(X) \tag{3.43}
\end{equation*}
$$

From (3.41), (3.42) and (3.43) we get
(2) $X$ does not satisfy the constraints and hence

$$
\begin{equation*}
\underset{V}{\operatorname{Max}} F(X, V)>B^{+} \tag{3.44}
\end{equation*}
$$

It follows then that

$$
\begin{equation*}
F\left(X^{*}, V^{*}\right)<\operatorname{Max}_{V} F(X, V) \tag{3.45}
\end{equation*}
$$

and $X^{*}$ is a locally minimizing point of problem (VI).
( $\varepsilon$ ) From she assumption we deduce that $X^{*}$ satisfies the contrainst. Then

$$
\begin{equation*}
F\left(X^{*}, V^{*}\right)=f\left(X^{*}\right) \tag{3.46}
\end{equation*}
$$

For every feasible point $X \in W_{1}\left(X^{*}\right)$ we have

$$
\begin{equation*}
F\left(X^{*}, V^{*}\right) \leqslant \operatorname{Max}_{V} F(X, V)=f(X) \tag{3.47}
\end{equation*}
$$

From (3.46) and (3.47) we deduce

$$
\begin{equation*}
f\left(X^{*}\right) \leqslant f(X) \tag{3.48}
\end{equation*}
$$

and hence $X^{*}$ is a locally minimizing point of problem (III).
